This group of authors used a suprasystolic pressure to produce a reactive hyperemia. This is probably an entirely harmless procedure in patients whose peripheral arteries show no organic disease and the resulting increased inflow will dilate the peripheral vascular bed. Bettmann^{28a} showed an increase in the size and number of capillaries after such a procedure. In patients suffering from obliterative vascular disease, the production of even a short asphyxia and of pressure on an inflamed or degenerated vessel is inadvisable. Besides, as shown by Freeman,²⁰ the oxygen debt incurred during the arterial obstruction is accurately repaid after release. Reactive hyperemia following arterial constriction is fundamentally nothing but the repayment of an oxygen debt. An excess amount of blood flow occurs only when damage of tissue has been produced by the arterial occlusion. It would seem to us, then, that although reactive hyperemia after arterial occlusion does produce an impressive vasodilatation and an increase in temperature it just barely compensates for the previous asphyxia and, with partially obstructed channels, this compensation will not be adequate.

THE APPLICATION OF VENOUS CONSTRICTION

Bier used soft rubber tubing for venous stasis; this was produced from one to several hours a day. While he recorded some observations on reactive hyperemia

in cases of arterial ligature and of arteriosclerotic and juvenile gangrene, a systematic series of treatments was advocated only for acute and chronic pyogenic infections, tuberculous processes and gas gangrene. One of his followers, Henle,²¹ felt that the constricting pressure should be measured and brought out a rubber cuff that was inflated from 60 to 100 mm. of mercury. Thies²² was the first to point out that hours of continuous venous compression would lead to very cumbersome and intractable indurations and advocated intermittent pressure and release. He first built an apparatus that was filled and intermittently emptied by water; later he used a carbon dioxide tank and finally an air pump to produce alternate pressure and release. He used venous compression for sixty seconds, followed by a release from ninety to 120 seconds. Thus he empirically discovered, as Goldblatt⁵ had found in the animal experiment, that the duration of the release should be at least as long as that of the obstruction, preferably longer. He treated sixty-three cases of joint infections and gas gangrene in a base hospital and reported very favorable results. He warned of using the alternating pressures for more than ten days but would occasionally maintain a treatment continuously for eighteen hours.

Quite recently Collens and Wilensky²³ introduced the method of alternate constriction and release in the treatment of peripheral vascular disease. They never employed pressures over 60 mm. of mercury in congested, ulcerated or gangrenous legs and prefer to use 40 mm. of mercury. When the outstanding symptom is intermittent claudication, pressures up to 90 mm. may be applied. Judged by the subjective improvement of the patients and by objective criteria, which are admirably simple and clinically useful, their results are impressive. A further discussion of their method will be given in the comments. Our own investigations served the purpose of (1) determining, by the help of objective methods, the changes in circulation following rhythmic venous compression, (2) constructing a simple apparatus by which inflation and deflation of the cuff could be obtained at varying pressures and time intervals adaptable to the patients' individual needs, and (3) establishing the value of this procedure, which is chiefly intended for home treatment over a prolonged period of time.

OWN OBSERVATIONS ON INTERMITTENT VENOUS HYPEREMIA

A. Blood Pressure Readings.—When a rubber cuff is thrown around the thigh and inflated to a subdiastolic pressure, the following changes occur: The veins stand out conspicuously on the dorsum of the foot and may show a venous pulsation; the toes become pink or dusky red in from ten to 120 seconds, depending on the degree of circulatory embarrassment, environmental temperature or arteriolar spasm; the patient feels a light sense of fulness and a mild throbbing at the point of constriction, which increases with the duration of pressure; when the pressure is released, a warm wave of blood seems to rush into the congested extremity. All observations recorded here were made following the produc-

tion of a pressure of 80 mm. of mercury for two minutes and a release for from two to four minutes.

Graph I shows four oscillometric curves taken at the right ankle of a patient with normal peripheral circulation. It can be seen from these curves that venous constriction produced an increase in the height of the spikes but no difference in the systolic and diastolic pressures. Immediately after release there is a further increase in pulsation but a decrease in systolic and diastolic pressure. Four minutes after the release of the cuff, the systolic and diastolic pressures have regained their original values but the length of the spikes has further increased. The comparison of the first and fourth curves illustrates a marked change in circulation.

In graph II, a patient's lower extremities showing normal peripheral circulation have been placed under a

of mercury after the release. An increase in the height of the spikes occurred even though, at the first reading, the legs had already been exposed to heat for thirty minutes.

The same procedure carried out on a lower extremity, sympathectomized for Raynaud's disease, resulted in very marked changes after venous compression and release, as shown in graph III. As control and reflex-toric vasoconstriction was abolished in this extremity, the atony of the minute vessels in response to mechanical stretching is striking. A similar result was observed by Capps,¹³ who showed that following an injection of alcohol into the stellate and upper dorsal ganglions the increase in volume of the limb after slight venous pressure was considerably higher than before the injection.

Such increments in pulse waves can be observed also in patients suffering from arterial disease, although the

Fig. 1.—Graph I. The subject's lower extremities were exposed to room temperature of 78 F. for thirty minutes. The cuff of the manometer was at the ankle and the constrictor on the thigh. Curve 1 is the control curve. Curve 2 was obtained after thirty minutes of intermittent constriction and release, at the end of constriction and curve 3 two minutes after release. Curve 4 was taken four minutes after release of the same constriction. There was a progressively increasing pulse volume after each phase of the treatment. Note that four minutes after the release of compression the reactive hyperemia was larger than after two minutes.

Graph II. This subject's lower extremities were placed in a heat cradle under thermostatic control and exposed to 85 F. for thirty minutes. At this time curve 1 was obtained at the ankle. A constrictor was then placed on the thigh and inflated to 80 mm. of mercury, this being the individual's diastolic pressure. After two minutes of venous compression the second reading was secured. Note that the pulse waves appear at 145 mm. of mercury compared with 135 mm. during the control period. Two minutes after release the third curve was run, showing a further dilatation of the peripheral vascular bed and a shift of the oscillations to the right, indicating decreased resistance. These curves were obtained during dilatation with heat and after one cycle of treatment (two minutes of constriction, two minutes of release).

Graph III. This patient had had a lumbar sympathectomy a year previously for Raynaud's disease. The lower extremities were exposed to 75 F. for thirty minutes. The first curve indicates a marked vasoconstriction as a direct response to cool air. She then used rhythmic compression with 80 mm. of mercury at the usual rate for thirty minutes. Curve 2 was obtained at the time, during the end of compression;

curve 3, at the end of release. Because of the absence of reflex-toric vasoconstriction and because of the diminished tonus of the venocapillary bed, the mechanical dilatation of the vascular bed during compression and the chemical dilatation after release are more striking. Note also the shift of the spikes to the left during compression and the shift to the right during release, indicating increased and decreased peripheral resistance respectively. This shift to the left and right can be seen on all graphs but is accentuated in the sympathectomized limb.

Graph IV. This illustrates the effect of alternate constriction and release in a patient, aged 33, suffering from Buerger's disease. The reading was made at the ankle. The greatest increment in pulsation was obtained immediately after release (curve 1), whereas two minutes later the vasoconstriction again prevailed (curve 2). The curve taken during constriction shows only a slight opening of the vascular bed (curve 3). Curve 4 shows the control reading at rest. This patient later underwent a lumbar sympathectomy with marked clinical benefit.

Graph V. This illustrates the effect of fifteen minutes of constriction and release under a constant temperature of 85 F. Curve 1 is taken at the end of compression; curve 2 at the end of release. In an individual with normal circulation, exposed to moderate heat, the vasodilating effect after release is very definite.

Graph VI. This patient, suffering from diabetic gangrene, was placed on the oscillating bed of Sanders: curve 1 feet down, curve 2 head down and feet raised, curve 3 horizontal position. Note the rise in blood pressure when the feet are down and the fall when the lower extremities are elevated. In that position the venocapillary bed is emptied and peripheral resistance is decreased. The effect of the Buerger-Allen exercises is well demonstrated by these curves.

heat cradle, thermostatically controlled. The temperature was set for 85 F. It will be noted that both during constriction but particularly after release there was a further increase in the oscillometric spikes. The blood pressure of 135/80 mm. of mercury rose to 145/80 mm. during constriction and dropped again to 132/75 mm.

changes are naturally not as striking. In graph IV, readings were taken from a patient suffering from Buerger's disease with considerable vessel spasm. The highest spikes are shown immediately after release, whereas two minutes later the persistent vessel spasm again diminishes the pulse waves.

In graph V, two curves were obtained after fifteen minutes of compression and release, showing a good response after release. The temperature of the cradle was kept at 85 F. At the end of thirty minutes, however, both show much smaller spikes and a much smaller response.²⁴ This observation reminds one of the interesting animal experiments of Goldblatt, who found that, unless enough time was allowed to elapse after constriction, repeated arterial occlusions were followed by a refractory stage. He stated that repeated venous compression did not result in a refractory stage, but it must be remembered that if such venous constrictions are carried on for a period of thirty minutes a severe anoxia may result.

Because it was felt that, especially in patients with arterial obstruction, the venocapillary bed could not sufficiently empty during the period of release, the

accomplishes this emptying by elevating the leg during treatment and by the help of the positive phase of the cycle. This can be readily accomplished by elevating the leg as in the Buerger-Allen exercises or by lifting it up with a pulley so that active muscular contractions, which consume so much oxygen, as pointed out by Reid, are avoided.

These considerations led us to adopt a triphasic cycle; namely, (1) elevation of the leg, (2) venous compression while the leg is still elevated and (3) horizontal position followed by release. The time ratios, which may have to vary according to the needs of the patient, will be described presently.

In interpreting the increased oscillations that follow both constriction and release, one must consider that the tightening of the cuff around the congested and later hyperemic extremity may be responsible for the

Fig. 2.—Graph VII. These curves illustrate the effect of placing the cuff of the blood pressure apparatus loosely (curve 1) or tightly (curve 2) around the ankle. Note the rise in systolic and diastolic pressures when the cuff is tight.

Graph VIII. In this graph the recording cuff was placed above the constrictor to rule out the tightening effect of constriction and release on the cuff. Curve 1 is the control curve; curves 2 and 3 were obtained after a single constriction and release respectively. The effects are similar to those obtained with the recording cuff below the constriction. It illustrates that the mechanical stretch and the chemical dilatation during constriction and release are not simulated by the tightening of the recording cuff.

Graphs IX and X. These curves were obtained from an upper extremity of an arteriosclerotic patient aged 60; the recording cuff was

above the constrictor. The effects are shown in curve 1 as control, curve 2 during constriction and curve 2 on graph X after release. Note that in this case there occurred a vasoconstriction in the extremity above the inflated cuff, which is probably on a reflex basis, originating in the pressure of the cuff. After release, vascular relaxation is obvious.

Graphs XI and XII. These indicate the duration of reactive hyperemia, after two minutes of compression with 80 mm. of mercury: (1) immediately after release, (2) one minute after release, (3) three minutes after release, (4) four minutes after release and (5) six minutes after release. It would seem that alternate constriction and release must be so arranged that enough time is given for the full development of the reactive hyperemia. In this instance a ratio of 1:3 brought about the maximum response.

stagnating blood was emptied by elevating the leg just before a renewed compression. The effect of gravity on the blood pressure of an extremity has been emphasized by Bier,³ Pearse and Morton²⁵ and Mont Reid.²⁶ In graph VI we show the pulse of a diabetic extremity on an oscillating bed in the horizontal, Trendelenburg and reverse Trendelenburg positions. When the leg is elevated, not only does the arterial pressure fall but the venocapillary bed empties and makes room for fresh blood. The alternating suction and pressure apparatus

increased oscillations. That this actually happens is shown in graph VII, in which the cuff was first applied loosely and then tightly at the same level under identical external conditions. But it must be remembered that the tight cuff produces a venous compression "per se" and therefore this experiment could not be of decisive value. It had to be shown that increased pulsations could be obtained following venous constriction, even though the cuff remained loose. Therefore the cuff of the automatic sphygmomanometer was placed above the constrictor and not below, as in the previous experiments, in which the venous compression readily causes an increase in limb volume and, in turn, a tightening of the cuff.

24. Graph omitted because of lack of space.

25. Pearse, H. E., Jr., and Morton, J. J.: The Blood Pressure in the Arteries of the Extremities in Normal Subjects and in Patients with Peripheral Vascular Disease, *Am. J. M. Sc.* 153:485 (April) 1932.

26. Reid, M. R.: The General Care of Peripheral Vascular Diseases, *Ann. Surg.* 96:733 (Oct.) 1932.

Graph VIII shows a group of readings in which the constrictor was placed below the cuff of the sphygmomanometer. There seems to be little difference between the control curve and the curve taken during congestion, although there would seem to be a slight increase in both the systolic and the diastolic pressure, probably because of the increased resistance produced by the constrictor. Following release, one again observes a definite reactive hyperemia, with increased pulsation, the same systolic but diminished diastolic pressure, 10 mm. of mercury lower than during constriction. From these observations one may conclude that the increased pulse volume is not due to the tight cuff *per se*, as in these experiments the limb did not swell. In placing the constrictor below the cuff, another phenomenon became apparent; namely, a reflectoric vasoconstriction originating from the pressure of the constrictor. This reflex vasoconstriction, which has been studied by the help of a "pinch reflex" by Carmichael and his associates²⁷ and by Capps,¹³ varies, of

TABLE 1.—*The Saturation of Venous Oxygen During Various Forms of Passive Vascular Exercise*

Type of Procedure	Case	Before	At 20 Minutes	At 40 Minutes

Intermittent stasis and elevation. 2 minutes-3 minutes-1 minute	11	70.0	77.5	69.6
	12	69.8	55.6	62.6

The figures represent the percentage saturation of venous blood, drawn under oil from the femoral vein. In each case the carbon dioxide and oxygen content was determined by puncturing the femoral artery. The oxygen saturation of the femoral vein was used as an indicator of oxygen tension in the venous blood and in the tissues. It will be noted that in the first three cases, in which treatment was given by the A apparatus, a fall in venous oxygen occurred—most marked in case 2. In cases 4 and 5, in which treatment was given with apparatus B, the saturation rose. In case 6 treatment was given with apparatus C, which produced a marked fall as early as twenty minutes. In case 7 a mild continuous venous compression was given with 40 mm. of mercury. In cases 8, 9 and 10, intermittent compression of 80 mm. of mercury was given for two minutes, followed by two minutes of release. In cases 11 and 12 a period of two minutes of compression with 80 mm. of mercury, three minutes release and one minute elevation was employed.

course, in various individuals. It is well demonstrated in graphs IX and X. The release of the constrictor in the same individual, however, resulted in a satisfactory hyperemia. Both temperatures of 90 to 95 F. and a sympathectomy abolish this mild vasoconstriction.

Finally, the effect of repeated oscillometric readings was studied in a normal person. It can be seen (graphs XI and XII) that repeated readings at one, two, four and six minutes after the initial reading open up the vascular bed more and more and may thus serve as a simple test for the flexibility or rigidity of the peripheral vascular bed. Whether they have a prognostic significance in patients with arteriolar involvement remains to be seen.

B. Determinations of Venous Oxygen Saturation.—In yet unpublished observations, Hick and de Takats²⁸ studied the effect of various therapeutic measures on the oxygen content and saturation of the femoral vein draining the treated extremity. Some of these observations relate to the behavior of oxygen saturation during

treatment with different types of suction apparatus and during continuous and intermittent venous hyperemia. Table 1 presents our results expressed in percentage of saturation of venous oxygen. In all these patients the oxygen capacity and the saturation of the arterial blood were normal. To save space we are presenting only the comparable end results of many determinations, all of which were run in duplicate. Treated with suction apparatus A, the first three individuals maintained their oxygen saturation at twenty minutes fairly well, but after forty minutes an unsaturation is definite, especially in cases 2 and 3. Patients 4 and 5, treated with apparatus B, maintained and even increased their venous oxygen content and saturation.²⁹ When continuous stasis was produced with 40 mm. of mercury, the figures behaved very similarly to those seen during the use of apparatus A. When intermittent venous compression was produced, with pressures and cycles recently advocated,^{23a} similar signs of venous stasis and consequent anoxia appeared. Finally, by prolonging the phase of release and emptying the venocapillary bed by posture, the saturation is fairly maintained in spite of the fact that the venous compression is produced with 80 mm. of mercury.

It seems that with certain types of apparatus, in which long negative and short positive cycles are used, the oxygen debt incurred during the negative phase and due to compression of the thigh is not repaid at the end of treatment. The same condition occurs when a mild continuous stasis is used or if the compression is intermittent, but a thorough emptying of the stagnating blood is not permitted. In all these treatments, a "stagnant anoxia" is produced with lowering of oxygen tension in the tissues. Only the last type of intermittent venous hyperemia effects a repayment of the oxygen debt during treatment.

At first glance one might be led to believe that, with the arterial oxygen content remaining the same, the drop in venous oxygen content and saturation must mean an increased utilization of oxygen in the tissues. This would be true if the rate of blood flow through the capillary bed would remain constant. The contrary is true, however. The blood flow is diminished, since the oxygen consumption must remain nearly constant, yet the arteriovenous oxygen difference is found to increase. This means a lowering of tissue oxygen tension.¹⁶

We are well aware of the fact that the paucity of data does not permit conclusions; also that certain variable factors make comparable controls very difficult. We wish to present a method by which various therapeutic procedures can be tested. The observations made during a cycle of compression, release and elevation support our previous observations with the recording sphygmotonomograph that reactive hyperemia must be given enough time for the full repayment of the oxygen debt.

PRACTICAL APPLICATION OF THE METHOD

Any blood pressure apparatus can be used to produce intermittent venous hyperemia, but a wide, 8 inch cuff, conically shaped to fit the thigh, is preferable as the pressure is distributed over a larger surface and the same amount of pressure that is painful when exerted by a narrow cuff is comfortable. The amount of pressure should not exceed the diastolic pressure of the extremity at that level. It varies between 90 and 60 mm. of mercury in an extremity of which the toes are not edematous, not cyanotic, not ulcerated and not gangrenous. When the foregoing conditions exist, 40 mm.

28. Hick, F. K., and de Takats, Geza: The Effect of Sympathetic Ganglionectomy, Alternating Negative and Positive Pressure and Alternating Constriction and Release on the Oxygen-Saturation of Venous Blood, to be published.

29. Patient 6, treated with apparatus C, showed a marked drop of oxygen saturation as early as twenty minutes.

of mercury should not be exceeded at first, although with later improvement the pressures can be gradually raised. The duration of the venous compression is determined by the appearance of a definite rubor; this occurs in from one to two minutes when pressures of from 60 to 90 mm. of mercury are used. The duration of the release should exceed that of the compression; together with the one minute of elevation, which can be

Fig. 3.—Apparatus in use. For the home, the pulley can be screwed into a door jamb, or a wooden frame can be constructed.

kept constant, it should last twice as long as the compression. Thus two minutes of compression requires four minutes of release, out of which three minutes is in the horizontal position and one minute in the elevated position. The elevation can be active, but it is preferable to lift up the leg with the help of a pulley. Thus in the average case a cycle is completed in six minutes; two minutes compression, three minutes release, and one minute elevation. When the circulatory embarrassment is more pronounced, one minute compression will readily produce a rubor and is followed by one minute release and one minute elevation, a cycle of three minutes.

Ordinarily thirty minutes of this vascular exercise in the morning and thirty minutes in the evening are prescribed. The method is flexible and readily adaptable to the patient's needs. Should it be painful or uncomfortable, either the pressure or the duration of the individual cycle has to be adjusted in order to obtain maximum benefit. When the patient is very sick, a relative or a nurse may inflate and deflate the cuff and lift the leg (fig. 3).

RESULTS

We have selected ten patients from a large group for the study of this method.^{29a} These patients were so selected that a close follow up could be instituted and repeated examinations were possible. Our observations are summarized in table 2. We are deeply conscious of the difficulties of evaluating the effects of any form of therapy in peripheral vascular diseases. In the first place, the spontaneous progress, remission and stationary periods, the effects of climate, season and barometric

29a. The number of patients who have taken at least sixty hours of treatment has now risen to twenty-five. Our impressions regarding the value of this method have been further confirmed. Favorable results have been obtained in three patients suffering from Buerger's disease, who have had lumbar sympathectomies. As shown in graph III, the effect of stretching of the venocapillary bed is very marked in the sympathectomized limb. As intermittent claudication is a symptom hardly influenced by sympathectomy (The Value of Sympathectomy in Peripheral Vascular Disease. Surgery, to be published), intermittent venous hyperemia seems to be a useful after-treatment for patients who had previously undergone sympathectomy for Buerger's disease.

pressure are not within control. Secondly, other forms of therapy that have an established value have been continued, as we did not feel justified in withholding any drug or method that in our past experience has proved helpful. Nevertheless, from our past experience with treatments of different types we regard the intermittent venous hyperemia as a valuable adjunct, an exercise for the home, which can be carried out over a period of months with very little expense and loss of time to the patient.

No results have been obtained in one case of Buerger's disease—and this is in harmony with observations made in our preliminary report on the Herrmann apparatus.³⁰ The rather striking improvement in our second case of Buerger's disease may be explained by the abstinence from tobacco which was instituted at the same time. Patient 7, with a severe form of arteriosclerosis with sclerotic but patent major arteries, did get relief from his rest pain. He was, however, immobilized in bed for two weeks with mild continuous heat and received paravertebral alcohol injections. The beneficial effect of rest in bed is so outstanding that we regard it as one of the most important factors in obtaining results. With the exception of this case, however, all other patients were ambulatory, using this exercise morning and evening, before and after work. Patients 1 to 6, suffering from arteriosclerosis or arteriosclerosis with diabetes, have responded favorably. The best result has been obtained in patient 4, a man whom we had the opportunity to observe three times a week for a period of two months, as he took his treatment in the

TABLE 2.—Observations on the Effect of Intermittent Venous Hyperemia on Peripheral Vascular Diseases

Case	Age	Diagnosis	Hours of Treatment	Effect on				Additional Treatment
				Coldness and Numbness	Claudication	Rest Pain		
1	72	Arteriosclerosis	60	+++	—	—		Theobromine

department of physical therapy. His treatment was stopped after forty hours; he was then given an outfit to use in the home.

Our criteria of improvement, as shown in table 2 are purely clinical and only roughly indicate the change in circulation. We have, however, individual instances in

30. de Takats, Geza: Obliterative Vascular Disease, J. A. M. A. 103: 1920 (Dec. 22) 1934.

which careful studies of the vascular status reveal an increase in collateral reserve. In our present state of knowledge it is not possible to decide just how long these treatments should be continued. But when a certain amount of improvement has been obtained we have discontinued treatment to see whether the results would hold. It seems logical to resume the treatments in periods of stress such as the spring and fall months exert on the vascular system. We have followed this principle for some years in giving typhoid vaccine in Buerger's disease during such seasons. That the summer months afford comparative relief to patients affected by vascular disease is obvious to those who study the attendance at vascular clinics in different months of the year.

A final aspect, namely, the mental outlook of the patients, should not be overlooked. These patients are afraid and truly in danger of losing a toe or a limb;

Fig. 4.—Home made apparatus. Note the double cuffs in use. The pulley is attached to a wooden frame. Note the automatic bell on the wall.

they have already tried different methods with questionable results. They hang their hope on the suction and pressure apparatus, which in our experience has occasionally given relief even when no suction and pressure were applied. The comforting feeling of some definite active form of treatment has been given to them by a short intensive course of treatment, which incidentally keeps them in bed, corrects their diet and permits a thorough study of their vascular status. When they leave the hospital, should this mental crutch be suddenly removed? The home treatment, which we confidently feel has a sound physiologic basis, offers them in addition the possibility to continue in active form a type of exercise which, unless the reserve capacity of the vascular bed is completely exhausted, opens, fills and stretches the venocapillary bed and dilates it as far as it will dilate.

COMMENT

We have been interested in finding a simple and inexpensive substitute for the negative pressure apparatus.

Certain advantages of this intermittent venous hyperemia over treatment with alternating suction and pressure are as follows: The treatment (1) can be used at home, at comparatively little cost, far away from medical centers, (2) is therefore available to a larger mass of people, and (3) has a more logical cycle of constriction and release and is readily adaptable to the circulatory embarrassment of the individual patient.

There are obvious disadvantages of this method. It requires an active participation of the patient and cannot be used except with outside help for desperately sick patients, such as we encounter in the acute arterial occlusions. In bilateral lesions, which are so frequently encountered, it necessitates the use of double cuffs with simultaneous elevation of the two lower extremities (fig. 4); this may be cumbersome to some patients. Finally, it may lead to unsupervised self treatment in the home—but this objection is valid for any type of heat, lamp or exercise that may be prescribed for the home.

On the basis of our oscillometric readings and determinations of venous oxygen content and saturation, we suspect that the present cycles used on some of the pressure appliances are not optimal. This is accurately reflected in the diminishing saturation of venous blood with oxygen. On one machine, in which a cycle of 1:1 ratio (even negative and positive cycles) can be produced, the results seem gratifying and the venous oxygen is maintained. It must be remembered, however, that none of these machines produce longer phases than twenty seconds and that the period is scarcely enough to fill and stretch a vascular bed with a normal arterial inflow. In an extremity in which the blood pressure is low and in which the blood flow per minute is cut down to one third or one fourth of the normal, it must take longer to obtain a maximal filling of the minute vessels. Therefore we postulate at least a constriction of one minute to obtain a mechanical stretching of the vascular network, preferably more.

We do not wish to imply that the treatment by alternating negative and positive pressure operates wholly on the basis of intermittent venous hyperemia. There is undoubtedly a partial release from atmospheric pressure of the cutaneous vessels, and this vascular massage of the skin may have reflectoric circulatory effects on deeper structures. But we maintain that there occurs with every phase of suction a marked compression of the thigh and that all the subjective and objective phenomena described as occurring during and after such treatments can be reproduced more simply by alternating constriction and release.³¹

All the contraindications to the treatments by suction and pressure that exist are to be observed in treating patients with intermittent venous hyperemia. They are spreading infection, thrombophlebitis and widespread arteriolar destruction. Because of our comparatively long venous compression from one to two minutes, patients exhibiting venous stasis, cyanosis or gangrene must not be treated with higher than 40 mm. of mercury, as emphasized by Collens and Wilensky.^{22a}

One must guard against an attitude of the patient or the attending physician that such a method effects a cure of peripheral vascular disease and that it provides

31. After the completion of this manuscript there appeared an article by Theis and Freeland (Peripheral Circulatory Diseases, J. A. M. A. 107:1097 [Oct 3] 1936) in which it was stated that alternating positive and negative pressure treatments act by increasing the metabolism of tissues. Their evidence was based on a drop of venous oxygen saturation. Our interpretation of this observation, as outlined in the body of this paper, is the creation of a "stagnant anoxia." The rise in surface temperature observed after such treatments is open to a number of interpretations and is not adequate evidence of increased metabolism.

new feet for the old. It is just one method of physical therapy to be used in combination with other methods of treatment. Its purpose is to halt the progress or slightly improve a progressive obliterative vascular disease of the peripheral arteries. As one of us emphasized in a preliminary report on alternating suction and pressure therapy,³⁰ the organic disease, which is usually systemic, will go on and the life expectancy of the limb will depend primarily on the condition of the vessels of the heart, kidney and brain, to mention the most important factors. But a local improvement of collateral circulation brought about by a mechanical phase of stretching the venocapillary bed and a chemical phase of creating an oxygen debt and repaying it with a reactive hyperemia offers subjective relief and occasionally saves a limb from major amputation.

A combination of intermittent venous hyperemia with methods that help to relax constricted vessels seems worth while, especially when vascular spasm is an important factor. We have always maintained that Buerger's disease is not strikingly influenced by alternating pressure therapy. We found the same to be true with regard to the rhythmic compression used intensively in two patients. A possible explanation is that the cuff pressure may provoke and aggravate the vessel spasm (fig. 1, graph V). Following sympathectomy, however, this reflectoric vessel spasm is abolished and the venocapillary bed can be dilated more effectively (fig. 1, graph III). We are now instituting such treatments on Buerger's disease following sympathectomy, unless they are in an active inflammatory stage.

Heat has been used in these patients with great moderation in the form of simple heat cradles. The temperature within the cradle should not exceed 85 F. More heat than this often aggravates pain, speeds up metabolism and calls for more oxygen than the diminished arterial flow can supply.

Vasodilator drugs show in the majority of cases a slight but unmistakable influence. We have little experience with other drugs than theobromine,³² but this with papaverine and phenobarbital are definitely helpful. In cases of acute arterial occlusion, papaverine is most effective.³³ The general care of patients suffering from peripheral vascular disease has been described elsewhere.³⁴ Undue emphasis on any one therapeutic procedure, be it medical, surgical or physical, spells, sooner or later, a disillusionment.

SUMMARY

The simple method here described produces intermittent venous hyperemia combined with postural emptying of the venocapillary bed and has an effect on the mechanical filling and stretching of the vascular tree, on the chemical vasodilatation as a result of an oxygen debt, on capillary pressure, on lymph flow and on the saturation of the tissues and the venous blood with oxygen. The method may prove helpful as a home treatment for patients suffering from obliterative vascular disease but should be used in combination with other recognized forms of conservative and surgical therapy. The general cardiovascular status, its progressive or stationary trend, will determine the ultimate result of any local therapy.

HYPOGLYCEMIC THERAPY

REPORT OF EIGHT CASES

H. MASON SMITH, M.D.

TAMPA, FLA.

Publicity in the press and the keen interest of the medical profession regarding reports from European clinics of the remarkable results obtained through the use of hypoglycemic shock therapy in the treatment of dementia praecox caused the Committee on Public Education of the American Psychiatric Association to warn both the public and the profession about this new therapy. As mentioned recently in *THE JOURNAL*,¹ the public statement was concurred in by all members of the committee and also by the president of the association, Dr. C. Macfie Campbell. In this warning it was stated that the impression that there is no treatment for dementia praecox except through insulin therapy is entirely erroneous and that the insulin shock treatment is being studied in the New York and Massachusetts state hospital systems, in Bellevue Hospital, New York, and in other scientific centers but is not to be undertaken except by those adequately trained to meet its dangers.

Reports² of European clinics show that 75 per cent of the patients ill less than half a year are completely recovered as a result of this therapy and that more than 69 per cent of those ill less than a year and a half become productive, socialized individuals able to resume work. Especially does it merit consideration since there is no other treatment for dementia praecox that has proved effectual. Spontaneous recovery occurs in this disease in less than 10 per cent of the cases. The remaining large percentage consists of chronic and incurable patients with a very long expectancy as custodial insane persons, most of whom become charges of the state. In 1934 there were 150,000 of these patients in state hospitals, and 19,149 new patients were committed in 1935.³

The hypothesis that Sakel applied successfully in cases of narcotic addiction and with startling results in cases of schizophrenia⁴ seems to be applicable also to at least some neuroses. In my practice psychoneurotic patients, some of them problems for years, are responding to this therapy. In the management of neurotic patients, however, the insulin is neutralized before shock occurs, but in cases of schizophrenia the hypoglycemic shock is the criterion or instrument that produces the benefit. As numerous investigators are agreed, it seems that the carbohydrate metabolism of the central nervous system is stimulated by insulin therapy, improved function resulting.

Grave dangers undoubtedly attend the treatment, particularly in the second of the four phases outlined by Sakel.⁵ In this period of shock a physician should be in constant attendance, and the attendants should be ready for all emergencies. Emphasis is to be placed on the careful guarding of the circulatory system. There

is danger of lasting injury to the heart in too great reduction of the sugar content of the blood. In most cases the coma results from the reaction to insulin rather than from the hypoglycemia, and determination of the blood sugar content in the hypoglycemic state is therefore of practically no value in determining the dosage of insulin. Apart from certain guiding principles, the therapy is individual in character, and both the depth of the shock and the number of shocks given depend largely on the intuition and good judgment of the physician in charge.

The variability of the reaction of the individual patient and of different patients to insulin is amazing. Patient 3 of this series walked around the hospital in apparent comfort after receiving a dose of 310 units. In other cases shock followed the administration of 25 units. Patient 1 went into such a deep coma that the administration of dextrose intravenously failed to restore him to consciousness. Usually the accumulation of a thick viscid mucoid saliva offered a problem. In case 2 pneumonia followed aspiration, an ever present danger. The suction machine was used and atropine freely administered in this series of cases. Since epinephrine reduces the shock, it was not used unless a convulsion or a circulatory disturbance was threatened. Arrangements have been made to use bronchoscopic suction with the next patient who aspirates.

The treatment can be carried out successfully in any general hospital that has a good psychopathic ward with a trained personnel of physicians and nurses. Indeed the dangers are more readily avoided and the emergencies more easily met in such an institution than in a psychopathic hospital. Also, treatment in a general hospital obviates the necessity of committing many patients to state institutions, a consideration usually of great importance to the patient's family and of economic significance to the state as well. The following reports of eight unselected cases of psychosis and neurosis show the feasibility of administering this treatment in a well equipped general hospital:

REPORT OF CASES

CASE 1.—A truck driver, aged 20, white, was admitted to the Tampa Municipal Hospital Dec. 16, 1936, in a disturbed mental state. He stated that while driving his truck he would be unable to remove his gaze from a house or other object on which it chanced to fall and added that his mind failed to tell him when he was physically fatigued. A good student, he was deeply concerned, he said, about the Bible, which until six months previously he had been unable to understand but now comprehended fully. Not he but the world without was disordered, he felt, and others could tell all that passed through his mind. He grimaced, displayed peculiar mannerisms and gave evidence of emotional poverty. He appeared to be wholly indifferent to his environment. After a night in the hospital he held his neck, believing it injured by gas, with which he thought he had been put to sleep. He also believed that waves of electricity, with which he thought he was being treated, were passing through his body. Except for vagotonia, physical examination was negative.

Anxious to avoid commitment, his family insisted on institution of hypoglycemic shock therapy at once, even though no literature on Sakel's method was as yet procurable. Accordingly the patient, fasting, was given 20, 35 and 55 units of insulin on succeeding mornings without any reaction. The drug was then administered every two hours until he lapsed into coma late on the night of December 24 after receiving 172½ units. Two hours afterward he had an epileptic seizure of eight minutes' duration. He was allowed to remain in the coma for four hours and was normal the next morning. He went home two days later.

After eight days pronounced symptoms returned, and the patient was readmitted to the hospital, Jan. 7, 1937. By the

administration of 60 units of insulin at 6 o'clock in the morning and 40 units two hours later, four wet shocks were produced and interrupted without difficulty. Following the fifth shock, however, he remained in the coma. Fifty cc. of 50 per cent dextrose was administered three times at intervals of two hours; epinephrine was given and at one time coramine and caffeine. That night a clonic spasm of forty minutes' duration occurred. After forty hours he came out of the coma in a normal state.

The next day Sakel's original article arrived, and translation revealed how great had been the deviation from his technique in the management of this case. The patient, after being subjected for one week to the polarization phase of Sakel's treatment, was discharged as well, January 24. He is completely rehabilitated, has gained in weight and has returned to work.

CASE 2.—An attorney, aged 30, white, admitted to the Tampa Municipal Hospital Jan. 16, 1937, gave a history of nervousness since an attack of influenza eight years before. In August 1933, while in court defending a client for murder, he had experienced his first hallucination in the form of a radio voice talking to him. Shortly afterward, believing he was about to be murdered by a client who had come to his office intoxicated and armed, he had entered into a state of anxious excitement and had finally collapsed. After two months and then ten months in the state hospital, with an intervening six months' period at home, he had come home again only to converse continually with the radio voice and to become threatening and pugnacious, showing homicidal tendencies. He had threatened his mother with knives and had thrown a piano stool at her.

On admission, he was restless, sleepless, irritable, pugnacious and at times noisy. After an initial dose of 20 units of insulin, given the patient fasting at 6 o'clock in the morning, the dosage was increased 5 units daily until a wet shock resulted on administration of 70 units. He had thirty-five shocks, interrupted with Levine feedings until a nasal obstruction prevented, and dextrose was then given intravenously. Following aspiration during the last period of shock, pneumonia developed in the left lung, but he recovered readily. He was discharged March 14.

The patient made a satisfactory social recovery. He is now thoroughly amenable to life at home and is able to do some legal work. Treatment will, however, be resumed in sixty days.

CASE 3.—A white man, aged 35, admitted to the Tampa Municipal Hospital Jan. 18, 1937, was the son of a prominent New England physician and the brother of a New York surgeon. He had been a normal boy and an average student. At the age of 16 years a subacute nephritis had developed, which cleared up entirely six years later when mental symptoms developed. At a state hospital in New England his case was diagnosed as dementia praecox of the catatonic type, and during the thirteen years intervening before he came under my observation this diagnosis was repeatedly confirmed elsewhere. Although apparently interested in some things, he had during all these years remained negativistic, catatonic and completely mute.

When admitted to the hospital, he was physically in perfect health and weighed 200 pounds (91 Kg.). He showed advanced catatonic symptoms but had some impulsive and spontaneous movements. In standing, his position was purely statuesque and he never batted an eyelid; but in all public places he would shake his head almost constantly, at first slowly and then rapidly, much as a bull does before charging.

The initial dose of 25 units of insulin, given the patient fasting, was increased each morning, at first by 5 units and then by 10, until after two months he was receiving 310 units without going into shock. Fortunately, 315 units produced a shock, and in all he had twenty shocks. In the preshock stages he talked and at times sang in a rather incoherent way, but with the termination of each shock mutism returned. Even before a complete shock occurred, the psychomotor restlessness ceased. Before he returned to New England, April 10, the rigidity and statuesque appearance were somewhat ameliorated, and he walked with less cataleptic appearance. In this case of thirteen years' duration the patient showed definite benefit.

CASE 4.—A white woman, aged 23, admitted to the Tampa Municipal Hospital Jan. 26, 1937, had suffered in infancy from colitis and then from infantile paralysis, as a result of which one leg was shorter than the other. She had neither talked

nor walked until she was 2½ years of age. From childhood she had been difficult to manage, and she had failed to develop emotionally into a well regulated adult. Nevertheless, she had completed the junior year of high school. For two years she had been running away, having hysterical tantrums and secluding herself in her room for long periods. Growing more and more infantile in demeanor, she had eventually become negativistic and pugnacious. Several times she had attacked her mother, to whom she attached all her difficulties.

To avoid commitment, she was admitted to the hospital and insulin therapy was instituted. The initial dose of 15 units of insulin was gradually increased to 50 units, the amount necessary to produce a shock. In all, she had four shocks, suffering a convulsion during the last one. She showed continuous improvement and was discharged, February 28. Subsequently she continued to improve at home until April 17, when she lapsed into her former condition.

CASE 5.—A white girl, aged 18 years, was admitted to the Tampa Municipal Hospital Feb. 13, 1937. While attending college in Virginia the previous fall she had broken down nervously, complaining of weakness and exhaustion and becoming at times hysterical or depressed. Having recovered, she had come to Florida in January. A few days after her arrival she began screaming, and in response to all questioning she but screamed the louder. After several days she grew quieter but lost interest in everything, remaining uncommunicative and refusing food.

Treatment in the hospital was begun with 15 units of insulin, and the amount was gradually increased to 50 units. Convulsions followed the first three shock doses, but epinephrine stopped this tendency. After the first wet shock she was normal for thirty minutes. She has had twenty-three wet shocks and now remains normal for two hours after each shock. Also she shows a much better reaction during the intervals between the hypoglycemic states. She is still under treatment.

CASE 6.—A cigar maker, white, aged 45, admitted to the Tampa Municipal Hospital March 13, 1937, was physically in perfect health. For a year he had had paranoid delusions with increasing frequency until he had begun to have hallucinations almost constantly. Voices talked about him wherever he went, he said, and when at work he would hear his wife tell him she was "stepping out" with young men every night. Fearing attack, he had been continually looking around while on the cigar bench and had refused to leave the factory at closing time.

He was apprehended and brought to the hospital for treatment. The amount of insulin given him was increased from 20 to 90 units, but the insulin was neutralized before shock occurred. At the end of two weeks all hallucinations had disappeared and the patient was discharged. His behavior has since been normal.

CASE 7.—A WPA worker, white, aged 30, was admitted to the Tampa Municipal Hospital March 27, 1937, in such a cloudy mental state that he could give no history. He had, however, had pneumonia a year previously and had been under great emotional stress for two years, his wife, father and brother having died of influenza. He had become greatly introverted, suffering many subjective sensations. Improper relationship with a woman had caused moral conflict. Found in a state of excitement digging into his wife's grave to see whether she was not dead but merely placed in a pasteboard box as voices had told him, he had been apprehended and transferred next day to the hospital.

On admission he displayed psychomotor restlessness, stared into space when quiet and showed no emotional reaction. Physical examination was negative. Fasting, he was given 15 units of insulin in the morning and after dinner a larger dose at 3 o'clock. The dosage was increased gradually until 50 units, given to the patient fasting, produced coma, which was interrupted within an hour. He improved after the third day and following the coma was normal. The dose was gradually reduced, and he was discharged April 10 as cured. He has gained in weight and returned to work. In this hysterical episode, recovery was effected very rapidly.

CASE 8.—A college boy, white, aged 22, admitted to the Tampa Municipal Hospital March 18, 1937, complained of phobias and depression. The illness had begun a year previously while he was living alone and working his way through college in Ohio. He had begun to fear on leaving home that

he had left a cigaret or a match burning. Seeing a bottle of oil of wintergreen while eating pie one day, he had begun to worry about being poisoned. He had become obsessed with the fear that everything he ate was poisoned and that poison got on him as he passed the chemical laboratory daily. Despondent and depressed as the phobias had grown more pronounced, he had had to discontinue his college work.

On admission, he gave no history of other illness and physical examination was negative. The blood sugar level was 144, but there was no reduction with Fehling's solution. Fasting, he was given an initial dose of 15 units of insulin in the morning and a second dose in the afternoon, the dosage being increased by 2½ units each time. He improved steadily during three days spent in the hospital and then returned to Winter Haven, Fla., where Dr. R. E. Gilbert continued the treatment in his office, administering the insulin in increasing doses twice daily and neutralizing it three hours later, keeping the patient meanwhile in his office. Shock was not entered into, but the maximum dose of 50 units caused a considerable degree of reaction. By that time the patient was free from all phobias, the depression had entirely disappeared and his mind was functioning better than it had for years. April 14 he returned to Ohio entirely recovered from the obsessive neurosis.

SUMMARY

Hypoglycemic shock therapy in the treatment of dementia praecox merits exhaustive study. As indicated by the accompanying reports of cases, insulin therapy has proved effectual in treating both psychotic and psychoneurotic patients. In accord with the opinion of numerous investigators, it is here suggested that insulin therapy stimulates the carbohydrate metabolism of the central nervous system.

AN OUTBREAK OF BOTULISM IN WYOMING

CAUSED BY EATING HOME-CANNED WILD MUSHROOMS

R. B. LINDSAY, M.D.
COKEVILLE, WYO.

J. R. NEWNAM, M.D.
KEMMERER, WYO.

AND
I. C. HALL, PH.D.
DENVER

The possibility of dying after eating certain species of mushrooms is so well known that probably few people partake of these delectable comestibles without harboring at least a subconscious thought that perhaps a mistake has been made in the identification, for which they may pay with their very lives. It is a curious fact that in all the literature on mushroom poisoning summarized by Ford,¹ Damon² and Jordan,³ one finds no reference to outbreaks which might have been due to botulism, and in all the literature on botulism we have found only one outbreak due to mushrooms, although Bachman in 1919 "isolated an organism from home-canned mushrooms which was morphologically and culturally like *Clostridium botulinum*" and which, "grown in meat, produced a toxin which when fed to chickens produced symptoms similar to limberneck."⁴

An actual outbreak of human botulism was ascribed to mushrooms by Meyer⁵ but a full account was never published. We are indebted to Dr. Meyer for a detailed account of this outbreak, which occurred in 1934 in San Francisco. The mushrooms had been purchased by an Italian family in San Jose, boiled for twenty minutes, placed in Mason jars, covered with olive oil and capped tightly. When opened six months later an "air noise" was noticed. The mother ate some of them before they were cooked and died from botulism in three days; three other members of the family ate them on two different days after they were cooked and suffered no ill effects. Unfortunately, none of the original material was available for laboratory examination, but Dr. Meyer saw the case personally and was satisfied that it was typical botulism, and the connection with the mushrooms was fully established epidemiologically.

Dr. E. C. Dickson of the Stanford University Hospital, San Francisco, who has had a long and extensive experience with botulism, stated in reply to our inquiry that he had never encountered botulism in connection with mushrooms.

Probably one reason for the scarcity of botulism after eating mushrooms is that, although they must frequently harbor the spores of *B. botulinus* from the soil, they are generally eaten while fresh or after preservation by drying and only rarely after home canning.

THE PRESENT OUTBREAK

The present outbreak occurred in the family of B. R., a rancher living about 5 miles from Cokeville, Wyo.

Thursday afternoon April 9, 1936, one of us (R. B. L.), while on his way by team and sleigh to visit a ranch several miles from Cokeville, was stopped by Mr. R., who lived nearby and requested to call on his return trip as one of Mr. R.'s children was not feeling well. On returning one hour later at 5 p. m. the father and mother were found to be greatly alarmed at the obviously precarious condition of their little girl, Joyce, aged 2½ years, who was evidently dying from respiratory failure. The pulse was strong and regular but no air was passing into or out of the lungs. Quick examination showed that there was no obstruction of the air passages. Lobeline was administered hypodermically and artificial respiration was attempted. Air passed freely to and from the lungs during artificial respiration but there was no natural respiratory response, and the heart action weakened and ceased in about four minutes. The parents said that the child had been sick only since morning; she had vomited a little and seemed drowsy. They did not think she had any fever.

Another girl, Alidde, aged 5½ years, was lying on the bed apparently unconcerned in what was going on. This naturally aroused suspicion but the now hysterical parents, on being questioned, denied that she was ill. Her pulse was found to be normal but she was staring glassily into space and did not wish to be disturbed; she would not answer questions. She was therefore raised to a sitting posture, whereupon her head dropped forward on her chest; she could not be induced to hold her head up, owing apparently to a definite paralysis of the muscles of the neck, simulating and immediately suggesting the "limberneck" of fowls, which is well known to be a form of botulism.

The parents were then questioned about having eaten home-canned or preserved foods. They first answered in the negative but a neighbor reminded them that they had been eating home-canned mushrooms. Mr. R. admitted this but said that they had been eating them for years and he was sure that they had nothing to do with the illness of his children. Further questioning elicited the fact that they had also been eating, among other things, home-made cheese, commercially canned tomato paste and home-cured sausages. Particular attention was directed to the mushrooms because a small remaining portion

appeared to be spoiled. Some of these mushrooms had been served at the evening meal Tuesday April 7, two days before the children became ill. All these foods were saved for examination.

Neither of the parents nor a 4 months old nursing infant showed any symptoms at this time. The infant was taken from the breast and they were advised to bring Alidde at once into the Lincoln County Miner's Hospital 45 miles away at Kemmerer, Wyo., but owing to the poor roads, which were impassable by automobile and difficult even for horses and sleigh, they did not arrive until 3 a. m., April 10.

At this time the sick child was reexamined by two of us (R. B. L. and J. R. N.). She showed marked prostration and was unable to answer questions except by whimpering sounds. She insisted on lying on her right side and when turned on her back began to struggle, gasp and choke. When water was placed in her mouth she was unable to swallow. The pupils were dilated and would not respond to light. There was marked muscular weakness so that she could neither sit up nor support her head when she was raised from the bed. The patellar reflex, however, was practically normal. There was no nausea, vomiting or looseness of the bowels. Examination of the heart, lungs and abdomen gave negative results. The clinical diagnosis of botulism was thus reaffirmed. A high enema and stimulants were administered and botulinus antitoxin was ordered from Denver. This serum was delivered by airplane⁶ and had to be dropped at Kemmerer by parachute because there was no landing field, but the child died from respiratory paralysis a short time before, at 3:32 p. m.

Both parents were tested for skin sensitivity to horse serum; Mrs. R., being found not sensitive, was given intramuscularly 50 cc. of botulinus antitoxin (type A, 6,125 units plus type B, 6,125 units). Mr. R., on the contrary, showed a positive skin reaction; several small doses of normal horse serum were administered at hourly intervals, gradually increasing to 10 cc., which gave no reaction. He was then given about 25 cc. of botulinus antitoxin (type A, 3,000 units, type B, 3,000 units), whereupon a marked serum reaction developed, with excessive perspiration, prostration, pulse 120, respiration 30, temperature 96 F. and generalized urticaria. Six minims (0.4 cc.) of epinephrine intravenously checked this reaction.

All the family were kept under close observation for one week. Neither Mrs. R. nor the baby ever showed any symptoms of botulism but Mr. R. complained of slight difficulty in swallowing during the second week, from which he completely recovered.

Subsequent to the outbreak it was learned that the mushrooms grew wild on the R. ranch. They were gathered during the spring of 1935, packed cold in quart glass jars with a little garlic and one teaspoonful of salt to each jar, and then steamed for four hours in a wash boiler.

On opening the mushrooms for use, Mrs. R. poured off the liquor, fried them in butter with tomato paste, garlic and spice, and served them hot. There was no suspicion of spoilage. How long they were heated is not known, but it is thought that they were removed from the fire almost at once; thorough heating would surely have destroyed the toxin.

LABORATORY STUDIES

A small remnant of the home-canned mushrooms was received at the laboratory in Denver, April 13. The contents of this jar were macerated, gassy and sour smelling. Microscopically there were numerous large gram-positive rods, gram-positive cocci and streptococci. The juice was easily filtered through paper and a Mandler filter. This filtrate contained a weak type A toxin of *Bacillus botulinus*; 3 cc. injected subcutaneously into a 400 Gm. guinea-pig produced the characteristic muscular weakness in forty-eight hours and death in seventy-two hours. This action was prevented by simultaneous injection of the same amount in a second animal with 1 cc. of type A botulinus antitoxin, while type B antitoxin had no preventive effect. These observations confirmed the clinical diagnosis of botulism.

No effort was made to isolate the various aerobic bacteria which were present, but a powerfully toxigenic strain of *Bacillus botulinus*, type A (No. 9184) was recovered from the mushrooms. One cc. of a dilution of 1:100,000 of a Mandler filtrate

5. Meyer, K. F.: The Frequency of Botulism, California & West. Med. 44: 388 (May) 1936.

6. Dr. A. A. Hermann of Denver, the Denver Post, and Governor Edwin Johnson of Colorado, cooperated in providing the serum and in its delivery by airplane.

prepared from a four day dextrose broth culture of this strain of *B. botulinus* injected subcutaneously killed a 250 Gm. guinea-pig in less than forty-eight hours with typical symptoms of botulism.

This raised the questions as to whether *B. botulinus* is capable of producing strong toxin in experimentally canned mushrooms and whether associated staphylococci or streptococci may interfere with toxin production. Fresh commercial mushrooms (*Agaricus campestris*) were rinsed, boiled ten minutes to destroy the tyrosinase and so prevent discoloration. They were then chopped fine, covered with water and a thin layer of vas-par in 250 cc. Erlenmeyer flasks half full, and sterilized in the autoclave at 120 C. for twenty minutes. Just before inoculation they were steamed in the Arnold sterilizer for twenty minutes.

Three such flasks of experimentally "canned mushrooms" were inoculated by gently displacing the vas-par seals. Each flask was inoculated with *B. botulinus* No. 9184 (type A) from the aforementioned outbreak, a 5 day old culture being used in deep brain medium suspended in sterile water and boiled for two minutes to destroy toxin and vegetative rods. A portion of this suspension was filtered through a Berkefeld filter before heating; 1 cc. of this filtrate killed a 450 Gm. guinea-pig with symptoms of botulism over night. Portions of the same filtrate boiled only one minute and two minutes (94 C.) failed in doses of 1 cc. to produce symptoms in five days in inoculated guinea-pigs. These controls insured that no preformed toxin was inoculated into the flasks of "canned mushrooms." One flask received no further inoculation; a second flask received in addition to *B. botulinus* a heavy inoculation of *Micrococcus aureus*, while a third flask received one of *Streptococcus pyogenes*. The upset vas-par seals were quickly reset by cautious melting with the Bunsen flame.

They were incubated at 37 C. Gas production started on the second day and continued vigorously throughout the entire period of incubation of seven days. When opened, all the flasks emitted a foul rotten odor. Aerobic subcultures on blood agar slants failed to show any unintended contaminations, but the inoculated staphylococci and streptococci were easily recovered. The fluid portions of all the flasks were easily filtered, yielding clear light brown filtrates.

Each of these filtrates was shown to contain approximately 10,000 minimum lethal doses of botulinus toxin per cubic centimeter by appropriate tests on guinea-pigs weighing from 525 to 600 Gm., thus proving that experimentally "canned mushrooms" provide a suitable nutritive pabulum for growth and production of a powerful toxin by *B. botulinus* and that the associated presence of *Micrococcus aureus* or *Streptococcus pyogenes* does not interfere with the formation of such toxin. We are unable to explain the weak toxin found in the home-canned mushrooms.

About twenty minutes after the death of the second child, a specimen of blood had been drawn. This was saved and was subsequently forwarded to the laboratory in Denver, where it was received April 15.

Both aerobic and anaerobic cultures made from this blood were sterile and a small guinea-pig inoculated with 1 cc. subcutaneously failed to show any symptoms. We have never been able to demonstrate botulinus toxin in the blood taken post mortem, but Glasmann⁷ succeeded repeatedly in our laboratory in demonstrating the toxin in extracts from the livers of animals that died from experimental botulism. This method has never been adequately tested as a means of postmortem diagnosis in human beings but should be tried whenever possible.

COMMENT

It is noteworthy that the possibility of mushroom poisoning in this outbreak was not even considered, botulism having been correctly diagnosed almost at once from the clinical signs.

It may be considered, however, that possibilities exist for clinical confusion of botulism and mushroom poisoning (mycetismus). First of all, the onset of symptoms in botulism only rarely occurs earlier than twelve hours after ingestion of the toxin, and the symp-

toms in order of appearance are diplopia and dilatation of the pupils of the eyes with dimness of vision, vertigo, aphonia, muscular weakness, dysuria, constipation, salivation due to strangulation, and respiratory failure. Nausea, abdominal cramps and vomiting occur occasionally,⁸ but diarrhea rarely if ever occurs. Terminal convulsions may be observed occasionally but never early in the disease. Patients suffering from botulism generally remain conscious until a few seconds before they die, and the heart is often observed to beat a few seconds after respiration ceases, as in the present instances. The mortality is high, between 60 and 80 per cent.

Mycetismus may be discussed briefly under five headings, as proposed by Ford.¹

In mycetismus gastro-intestinalis caused by certain species of *Lactarius*, *Entoloma* and *Lepiota*, all the symptoms are limited to nausea, abdominal cramps of variable intensity, vomiting and diarrhea. Neural symptoms never occur, and the mortality is low. There is no danger of confusion with botulism, but similar symptoms might be caused by other forms of food poisoning, notably those due to staphylococci, *Bacterium paratyphosum* or *Bacterium enteritidis*.

In mycetismus choleraformis, which is caused by *Amanita phalloides* and probably also by *Pholiota autumnalis* and *Hygrophorus conicus*, the onset is generally characterized in from ten to fifteen hours by violent abdominal cramps, nausea, vomiting and diarrhea, rapidly followed by loss of strength, the appearance of casts in the urine due to damaged kidneys, and heart failure. Liver function is also impaired. The mortality is high, about 50 per cent. Neural symptoms are absent and there is little danger of confusion with botulism.

In mycetismus nervosus, which is due to those mushrooms containing muscarin, such as *Amanita muscaria*, *Amanita pantherina* and certain species of *Inocybe* and *Clitocybe*, violent gastro-intestinal symptoms may appear within two or three hours, accompanied by contracted pupils, profuse perspiration and salivation, localized or generalized convulsions, delirium, hallucinations and death in coma with acute dilatation of the heart. Unless treated early with atropine, the mortality is high. There is little danger of confusion with botulism.

In mycetismus sanguineus, caused by *Helvella esculenta*, the outstanding symptoms are hemoglobi-nuria and abdominal distress followed by a mild persistent jaundice. The mortality is low and confusion with botulism should never occur.

The last form of mushroom poisoning, mycetismus cerebialis, caused by certain species of *Panaeolus*, is possibly the only one likely to be confused with botulism because of the disturbances of vision and the staggering gait. However, the earlier onset, from four to five hours, the exhilarating intoxication and the low mortality should serve clearly to distinguish it from botulism.

SUMMARY

In an outbreak of botulism, type A, due to home-canned wild mushrooms of unknown species in Wyoming, two children died but the parents were saved, probably by the accident of a weak toxin and the timely prophylactic administration of botulinus antitoxin.

8. Hall, I. C., and Gilbert, O. M.: A Survey of Botulism in Colorado with a Discussion of Recent Outbreaks, *Colorado Med.* 26: 233 (July) 1929. Hall, I. C.: Further Outbreaks of Botulism in the Rocky Mountain Region, *Am. J. Hyg.* 17: 235 (Jan.) 1933; New Outbreaks of Botulism in Western United States, *Food Research* 1: 171 (March-April) 1936.

7. Glasmann, V. E.: The Postmortem Diagnosis of Botulism, *University of Colorado Studies* 20: 36, 1932.

This is believed to be only the second outbreak of botulism caused by home-canned mushrooms and the first in which both the toxin and the bacillus were demonstrated by laboratory procedures.

In spite of the comparatively weak toxin, a strongly toxigenic strain of *B. botulinus* type A was recovered from the mushrooms, and both pure cultures and cultures of this mixed with *Micrococcus aureus* and *Streptococcus pyogenes* produced normally potent botulinus toxin.

A brief comparative summary of the differential symptoms of botulism and mushroom poisoning (mycetismus) indicates that these conditions need never be confused clinically.

4200 East Ninth Avenue.

ENCYSTED TRICHINAE

THEIR INCIDENCE IN A PRIVATE PRACTICE AND THE BEARING OF THIS ON THE INTERPRE- TATION OF DIAGNOSTIC TESTS

THOMAS B. MAGATH, M.D.

ROCHESTER, MINN.

Ever since those days when the early anatomists dulled their scalpels on the calcified cysts of trichinae in the muscles of cadavers, trichinosis has been a more common disease of man than generally has been recognized. Just how common it is in North America is not known but recent literature indicates that it is of far more frequent occurrence than most physicians have realized. In the United States many physicians apparently have thought that federal meat inspection regulations protected citizens, but there is evidence that critical evaluation of the actual effect of these regulations has been lacking. It is perhaps not sufficiently realized that only a part of the hogs consumed in the United States are killed in supervised abattoirs¹ and that the regulations do not provide for microscopic examination of the tissues of hogs.² Further, it may not be generally known that somewhere from 3 to 6 per cent of hogs are infected with trichinae.

The incidence of human infection with trichinae is still not known. The clinical diagnosis is attended with difficulty and great inaccuracy. Hall³ has collected more than forty diseases with which trichinosis has been confused and recently Otto and Janney⁴ have reported an outbreak in a family in which diagnoses including typhoid, influenza, encephalitis, mumps and alco-

holism were erroneously made. At present the only basis for establishing the incidence of the infection is that founded on examination after death. Unfortunately there have been but few such studies; a summary of these is given in table 1.

In addition to these studies Osler⁵ recorded that in 1,000 postmortem examinations performed by him in and about Baltimore he casually observed trichinae six times, and Mallory⁶ observed them twice without microscopic examination in 1,103 postmortem examinations done in Boston.

The exact method of examination is important, since the results will be influenced by it. It is fairly clearly established that the muscles of the thorax and neck are more likely to be invaded than other muscles; hence, these should be examined. Gross observation is almost valueless, since cysts will not be seen unless they are heavily impregnated with calcium and are present in large numbers. Sectioning will reveal but a small percentage. Queen⁶ found that, if large numbers of sections which have been specially prepared are studied, one can detect trichinae in only about a fourth of the muscle specimens in which the worms are actually present. A much better and easier method is to examine muscle in a compress with a low power objective. According to the care used and the amount of tissue employed, a fair number of trichinae will be discovered. Queen found 38 per cent positive by using two fields, 4 by 6 cm. If larger and more fields are examined, the increase in positives will be somewhat proportional. If large amounts of muscle are digested and the larvae extracted, more muscle may be used and more trichinae will be found. It may be safely stated, therefore, that the reported incidence of infection with trichinae is much lower than was actually present and was somewhere in the neighborhood of from 15 to 20 per cent. This is ample proof that citizens of the United States frequently eat raw or undercooked pork.

Of great significance is the observation that statistics from Europe, especially Germany, a country generally believed to exhibit a high incidence of trichinosis, indicate a much lower incidence of infection among bodies examined at necropsy or on the dissecting tables than in the United States. Indeed, if the surveys made in Germany are to be compared with those made in the United States, one would conclude that the incidence is about five times greater in the United States than in middle Europe.

The next question is whether the samples examined are representative of the population of today. It is evident that among the observations reported are only five made in the last thirty-five years and that those have come from charity hospitals and dissecting rooms and from only a few regions of the country. Only one survey was made in the northwestern part of the United States and that was of bodies found on the anatomic dissecting tables. With the exception of a few cadavers in St. Louis, a larger series in Minneapolis, a few hospital postmortem examinations made in Denver and one series in San Francisco, no studies have been made west of Buffalo except in New Orleans, and this is the only record from the entire South. Cadavers cannot be considered representative of the population.⁷ They

From the Division of Clinical Pathology, Section on Parasitology, the Mayo Clinic.

1. Under bureau inspection 28,506,019 swine were slaughtered in the last fiscal year. No one knows the number slaughtered other than under bureau supervision.

2. The following embrace the essential regulations governing the inspection of hog meat: The regulations governing the meat inspection of the United States Department of Agriculture require that no article of a kind prepared customarily to be eaten without cooking shall contain any muscle tissue of pork unless the pork has been subjected to treatment prescribed by the chief of the bureau, live trichinae. All parts of the muscle tissue of . . . to heat at a temperature not lower than 137 F., or shall be refrigerated at a temperature not higher than 5 F., for a continuous period of not less than twenty days, or shall be treated by curing as hereinafter prescribed. The pork or the articles of which it is an ingredient, after chilling or preliminary freezing, shall be stored in freezers maintained during the twenty-day period at a temperature not higher than 5 F. If the meat is stored in tierces it is necessary to make a sufficient allowance of time, namely, ten days, for the temperature of the meat in the center of the tierces to drop to the required level. Several methods of curing such meat as hams and pork butts intended to be used without cooking are also as prescribed. These methods vary somewhat according to the size of the pieces of meat, whether they are ground or whole. The amount of curing ingredients and how such ingredients are to be applied, as well as the time and temperature, are also regulated. No deviation from prescribed methods is permitted.

7. Hall and Collins (Studies on Trichinosis: I. The Incidence of Trichinosis as Indicated by Postmortem Examination of 300 Dissections, *J. Parasitol.* 22:532-533 (Dec.) 1936) thought the cadavers were representative of the general population. If they were, they differed markedly from cadavers coming into the dissecting rooms in institutions with which I am familiar.

represent those who are down and out, who live from hand to mouth and of necessity eat inferior and poorly prepared food of all sorts. In addition, they represent persons who are much older than the general population and frequently they are foreign born.

Patients from the charity hospitals are also not altogether typical of the population, since large numbers are foreign born and they too have lived, at least in the past, below the standard usually considered typically American.

With the hope of shedding some light on this matter I examined muscles from bodies of 220 patients of the Mayo Clinic who had died of various causes. While

It is impossible to give figures that would be indicative of the frequency of clinical trichinosis in this country. Until 1898 the diagnosis had been made in something like 900 cases and since then hundreds of cases have been observed. It is evident that in some cases the diagnosis has been trichinosis when actually the disease was not present and many persons infected with trichinae have never been given a diagnosis of trichinosis. It may be concluded, therefore, that clinical trichinosis is actually relatively common in the United States.

Unfortunately, there are few or no facts on which to base a true estimate of the infection among hogs.

TABLE 1.—Summary of Reports of Examinations Made for Trichinae After Death

Year	Author	Place	Number of Necropsies	Infected		Method of Examination

these patients had come from various states, most were from the North and the Middle West. They had been for the most part well to do but were not selected in any way. They died in 1935 or 1936. Almost all were adults. Pieces of the following muscles were procured: diaphragm, intercostal muscles, rectus abdominis and sternocleidomastoid. About 2 Gm. of each was compressed and searched with a binocular microscope equipped to magnify 25 times.

The results are seen in table 2, in which is recorded the degree of infection in the seventeen bodies (8 per cent of the total examined) in which trichinae were found.

It can be seen that although the diaphragm contained more trichinae than other muscles it was not always found to be involved in these examinations. A summary of cases can be had in table 3. It can be seen that symptoms suggestive of a history of infection were present in only seven, but in these the symptoms were readily explained on the basis of other conditions found. History of muscular pains is commonly enough given by persons in whose muscles trichinae are not found. Unfortunately, eosinophil counts were made in only five cases, but in these there was little to suggest infection. In short, the evidence here, as in the series reported by others, indicates that although infection with trichinae is common enough it is frequently, perhaps more often than not, subclinical in intensity and may not produce persistent eosinophilia. On the other hand, many cases of clinical trichinosis go undiagnosed.

In the light of previous work and from the observation that the infection of the persons whose bodies were examined by me was light, it seems safe to assume that, had the examinations included digestion or microscopic examination of from 50 to 100 Gm. of muscle, more larvae would have been found; therefore, the actual incidence of infection can be fairly safely assumed to have been of the order of 12 to 15 per cent.

Bushnell⁸ said that the incidence was 1.95 among hogs inspected from 1898 to 1906, but recent figures are not available. It is assumed that at present from 2 to 4 per cent of hogs in the United States are infected. Hence it is impossible to estimate the exposure to which the population really is subjected. Even the method by which hogs are infected is not clear. Recently it has been generally thought that rats and mice probably act

as reservoirs and infecting agents, since hogs eat these rodents. Examination of rats in slaughter houses has revealed that large numbers are infected, and those in sewers of cities are even more heavily infected. It is not clear, however, just what part these animals play in the general disseminating of the disease among hogs raised in the rural districts.

8. Bushnell, W. F.: Trichinosis as a Public Health Problem, *Journal-Lancet* 55: 42-46 (Jan. 1) 1935.

Since introduction of the skin test and precipitin test for the diagnosis of trichinosis, great increase in interest in the disease has been manifest. More specific knowledge of the significance of the tests is urgently needed. It is reasonably certain that in the presence of acute or even chronic trichinosis the tests give a high percentage of positive cutaneous reactions, but the proper dilution of the antigen to use is not established. Friedlander⁹ criticized Kilduffe¹⁰ for using a dilution of 1:100 and pointed out that the test was more specific when higher dilutions were employed. It has been suggested that the dilution should be 1:10,000 for detecting acute cases. McCoy, Miller and Friedlander¹¹ obtained 70 per cent positive reactions in thirty-six early cases at this dilution and 92 per cent positive reactions at a dilution of 1:500. Spink and Augustine¹² in thirty-four tests found thirty-three positive with a dilution of 1:10,000 but it is not clear that in all cases bona

gave positive skin reactions with dilutions of 1:10,000 and 18 per cent gave positive results with a dilution of 1:5,000; of forty-seven controls tested in San Francisco, 4 per cent gave positive reactions with a dilution of 1:10,000 and 6.5 per cent with a dilution of 1:500. In Louisiana of ninety-two persons tested, all infected with the whipworm, 18 per cent gave positive results with a dilution of 1:10,000 and 62 per cent with a dilution of 1:500. Augustine and Theiler found that, of forty Columbians tested, twenty-eight (70 per cent) gave positive skin tests with a dilution of 1:100; even with a dilution of 1:500 an equal number were positive. Kaljus found only 5 per cent "false" positives in testing 109 controls, using dilutions of from 1:1,000 to 1:2,000. He stated that the presence of whipworms did not influence the test.

From these observations it would appear that the skin test is usually positive in acute trichinosis even when

fide trichinosis was present; at least the parasite was not found in all the sections taken for biopsy. Drake, Hawkes and Warren¹³ made tests in twenty-six cases in which a clinical diagnosis of trichinosis had been made and obtained positive results with a dilution of 1:10,000. Augustine and Theiler¹⁴ found positive reactions at this dilution in nine of ten cases, but Heathman's¹⁵ experience was not so favorable. She tested forty-four patients and obtained a positive response in only 50 per cent with a dilution of 1:100 and only 12.3 per cent with a dilution of 1:6,000 and 1:500. The precipitin test gave 68.2 per cent positive reactions in thirty cases. Kaljus¹⁶ tested sixty-six persons who had early trichinosis and found 74 per cent positive skin tests with dilutions of 1:1,000 and 1:2,000.

The great difficulty with the skin test is the lack of observations on which to establish its value when the result is negative and lack of knowledge concerning the incidence of positive reactions it gives in the general population. McCoy, Miller and Friedlander found that of 104 so-called controls in Rochester, N. Y., 9 per cent

the antigen is used in high dilutions, and evidence indicates that years after acute infection a positive skin test still persists, but for how long, and how sensitive the skin remains to the antigen, is unknown. If infection is as common as microscopic examination indicates that it is, the test should be positive more frequently than evidence shows it to be and if the test does reveal light and long-standing infections, its interpretation when positive must be made with great caution. This suggests that in many cases in which a diagnosis of trichinosis is made on the basis of skin tests, and without biopsy, it may not be correct. Recently I saw a patient who had muscle pains, fever and an eosinophilia which at first was 14 per cent. The eosinophils increased to 21.5 per cent after ten days, and edema of the face and hands developed. A skin test with a dilution of antigen of 1:5,000 gave a slightly positive reaction, yet a liberal specimen of pectoral muscle, carefully examined, failed to reveal the presence of trichinae. The eosinophilia disappeared as rapidly as it had risen. The diagnosis of trichinosis had to be withdrawn.

Eosinophilia, especially rapidly increasing eosinophilia, is of extreme importance and probably is more important than skin tests. If a positive skin reaction is present at a dilution of antigen of 1:10,000, if eosinophilia is more than 10 per cent and is increasing, and if clinical symptoms of trichinosis are present, including fever, transverse facial edema and muscular pain, the evidence is certain enough to justify the clinical diagnosis of trichinosis.

SUMMARY

Although this is the only recorded series of microscopic examinations made on a relatively large number of unselected patients in private practice, it is clear that

they, although perhaps not so frequently infected with trichinae as are patients from economically lower walks of life, nevertheless often harbor the parasite. Exposure must be common.

From available knowledge it is evident that, in the United States, from 10 to 20 per cent of the adult population have acquired trichinae. Although some of these persons have experienced more or less typical symptoms of trichinosis, most of them never have had any signs suggestive of the infection having taken place. This makes interpretation of the skin and precipitin tests difficult, since it is not known whether immunity follows mild or even severe infection with this parasite.

Eosinophilia of more than 10 per cent, and especially rapidly rising eosinophilia, should suggest trichinosis. If, in addition, the skin test is positive in a dilution of antigen of 1:10,000, if a history of eating undercooked pork is obtained, and if typical symptoms are present, the diagnosis would appear almost certain. The final proof must still remain the demonstration of the worms in the body of the victim.

In spite of the fact that trichinosis has not received widespread consideration in the United States, one must conclude, on the basis of studies already made, that it is one of the major public health problems in this country and that there is still need of emphasizing the importance of cooking pork thoroughly before it is consumed.

HOW LARGE IS THE HYPERPLASTIC PROSTATE?

REPORT OF THE LARGEST HYPERTROPHIED PROSTATE EVER SURGICALLY REMOVED

RICHARD P. MIDDLETON, M.D.
SALT LAKE CITY

There is no clinical problem concerning which one may find a wider divergence of opinion among competent urologic surgeons at present than that of the applicability of transurethral resection to various types of obstructing prostates. At one extreme are those who assert that transurethral methods are properly applied only for sclerosis of the bladder neck (median bar) and prostatic carcinoma. At the other end of the gamut is a group, many of whose members are fortified by abundant experience, who claim to be able to resect successfully any prostatic obstruction that will permit passage of the resectoscope into the bladder.

Whatever may be the ultimate outcome of this divergence of opinion, the question at issue has lent practical value to a consideration of the actual size attained by the hyperplastic prostate. The early writers on the subject of transurethral prostatic resection were captivated with the idea that the removal of a very small amount of tissue would suffice—a mere nibbling at the lobes, or “cutting a groove” from the trigon down to the verumontanum. Growing experience, with its painful lessons afforded by incomplete results, has convinced those who persist with transurethral resection that uniform success can be achieved only by the removal of a considerable portion of the hyperplastic mass. Hence it is pertinent to inquire how much tissue the resectionist can remove through the urethra and what relationship this amount bears to that which remains.

Cunningham's "Text-Book of Anatomy"¹ describes the size of the normal prostate in terms of dimensions,

with no mention of weight. "Gray's Anatomy"² says of the normal prostate, "Its weight is about 8 Gm." This is curiously at variance with several other authorities consulted. Keyes,³ for example, gives the weight as from "16 to 24 grams" and Hinman⁴ says: "The normal gland weighs about 23 Gm. The average enlargement will not exceed 85 Gm., even the larger specimens weighing well under 200."

As regards the size attained by hyperplastic obstructing prostates, Alcock⁵ remarks in a summary of his experience with transurethral resection:

How much does the average hypertrophied prostate that is removed surgically actually weigh? These prostates vary greatly in size. A gland the size of a golf ball weighs 43 Gm., one the size of a hen's egg weighs 51 Gm., one the size of a lemon weighs 140 Gm., and one the size of an orange weighs 314 Gm. In the records of my own prostatectomies the weight of the gland removed was recorded in each of 433 cases; the largest was 270 Gm. and the average weight of the 433 was 38.3 Gm. Therefore, if with the resectoscope one removes from 15 to 35 Gm., one is removing a very large part of the average gland. In 85 per cent of the first hundred cases that I did by the resection method I removed less than 10 Gm. of tissue; in the last hundred—the eighth hundred—more than 10 Gm. was removed in 90 per cent of the cases, and in only 2 per cent was less than 5 Gm. removed. I know from my experience that it is absolutely essential to remove an adequate amount of tissue and I find as my experience has grown that I am removing larger and larger amounts of the gland. The largest amount removed at one sitting was 54 Gm.; the largest amount removed from one patient was 134 Gm. in three sittings. In the bulk of the cases now being done, from 15 to 35 Gm. is removed. . . . In general it may be said that from one third to three fourths of the gland is removed.

Emmett⁶ recently reported the transurethral removal of 112 Gm. of tissue from an "enormous prostate gland" of high vascularity. The operation was carried out in two stages, the bleeding being markedly reduced at the second operation by intraprostatic injection of solution of posterior pituitary.

The following case report is noteworthy because it concerns, as far as can be determined, the largest hypertrophied prostate that has ever been surgically removed and the second largest prostate on record in the world's literature:

G. A. M., a retired farmer, aged 72, of Swedish ancestry, was seen first March 13, 1936, in consultation with his family physician. The patient was in acute urinary retention and had been brought to the hospital when efforts to catheterize him at home had been unavailing.

During the preceding ten years the patient had noticed gradually increasing frequency, nocturia, urgency, and diminishing caliber of the urinary stream. From time to time there was some dysuria. For about a year he had been obliged to catheterize himself occasionally. Although this sometimes caused mild bleeding, he never before had failed to insert the catheter into the bladder. His general health remained fairly good, except for the usual disabilities of his age. Aside from the urinary difficulty his only complaint was of a mild chronic cough.

His past medical history was uneventful, with no serious illnesses. His wife and seven children were living and well. The family history was irrelevant as far as any tendency to prostatism was concerned. His father died at 80 of "old age."

At the time of admission to the hospital the patient, who was well developed and reasonably well nourished, was badly dehydrated and complained bitterly of distress from a full bladder.

1. Cunningham's Text-Book of Anatomy, ed. 6, New York, Oxford University Press, 1931, pp. 1279-1282.

A marked arcus senilis was present. The pupils were equal and reacted to light. Hearing was moderately impaired. The teeth were artificial. There was no adenopathy. The chest was moderately emphysematous, with reduced expansion and hyperresonant percussion note. There were no râles. The heart was not enlarged. Its rhythm was regular and there were no murmurs. The heart tones were somewhat distant. The blood pressure was 135 mm. of mercury systolic, 85 diastolic. Abdominal inspection and palpation revealed a tense tender tumor attributable to fulness of the bladder. The extremities were normal except for moderate arteriosclerosis. The external genitalia were normal. Rectal palpation disclosed a huge benign prostatic hypertrophy, which bulged so prominently that the examining finger was deflected sharply backward into the hollow of the sacrum. The upper border of the gland seemed far beyond the finger's reach. The consistency and contour were suggestive of benign hyperplasia, with no indication of malignancy. The great size of the tumor did, however, momentarily raise the question of prostatic sarcoma.

After several attempts with various catheters, the patient was relieved of 600 cc. of retained urine by passing a filiform to which was screwed an 18 French Phillips woven catheter.

Fragmented prostate weighing 557 Gm. (largest surgical specimen on record). One pound avoirdupois contains 453.6 Gm. Many of these pieces are as big as the typical large operative specimen. Photograph made four days after operation, when the specimen had shrunken considerably.

The catheter had to be passed until its whole length disappeared into the urethra before urine was drawn. There was slight bleeding.

The following morning suprapubic cystotomy was carried out under local anesthesia supplemented with a small amount of ethylene. The patient's condition was not particularly good, but the great difficulty of catheterization made immediate intervention imperative. When the bladder was opened an enormous mound of prostatic hypertrophy was encountered rising high into the vesical cavity so as practically to fill the bladder. Its consistency was smooth and elastic. The internal urethral orifice was stretched between the immense lateral lobes to form an anteroposterior slit long enough to admit all the fingers of one's hand. The mammoth gland seemed to fill the true pelvis like the head of a fetus at term. There were no palpable stones, vesical neoplasms or diverticula. A Pezzet catheter was inserted into the bladder and a small empty Penrose drain was left in the space of Retzius.

Two weeks later the patient's condition seemed well stabilized. Values for blood urea nitrogen and creatinine had become normal and the phenolsulfonphthalein excretion was 35 per cent, about equally divided between the first and second hours. Enucleation of the prostate was performed March 28, 1936, under spinal anesthesia with 100 mg. of procaine. The prostate was so tightly jammed in the pelvis as to make the ordinary peripheral cleavage plane inaccessible. It was therefore removed by morcellation, which was effected digitally through the many natural cleavage planes afforded by the hyperplastic spheroids. The resulting heap of chunks of tissue (many as large as the

typical operative specimen) appeared sufficient to fill a man's hat. Bleeding was only moderate. A large-size Pilcher bag was placed in the prostatic cavity, but the fit was like that of an egg in a bowl. The remainder of the cavity was filled with two large gauze packs. The incision was closed with interrupted silkworm gut sutures penetrating all layers and several sutures of chromic catgut.

The day after operation, there being no evidence of fresh bleeding, the gauze packs and Pilcher bag were removed. The urethral tube of the bag was utilized to draw a 20 French soft rubber catheter into position, after which the incision was allowed to heal. During convalescence the bladder was irrigated several times daily through the urethral catheter with sterile physiologic solution of sodium chloride. Except for moderate febrile reaction the patient made a smooth recovery, and there was very little spill of urine through the incision after the first two days. Fourteen days after operation the catheter was removed and the patient voided without leakage through the wound. He was discharged from the hospital April 20, 1936.

At the present time the patient is in excellent health and has normal urinary function, with a large free stream and perfect control. Cystoscopic examination three months after operation showed that the huge prostatic cavity had been almost completely effaced, with restoration of the original anatomic relationships at the vesical neck.

The prostatic tissue was examined by Dr. L. L. Daines, dean and professor of pathology at the University of Utah Medical School. His report reads:

"Specimen consists of many masses of prostatic tissue, the largest measuring 7 by 6 by 4 cm. Together, the masses weigh 557 Gm. (almost 1¼ pounds). There are many well defined rounded tumor-like masses and also flat fibrous masses.

"Microscopic sections show a benign, moderately cystic prostatic hyperplasia. There is no evidence of malignancy in these sections."

COMMENT

This is the largest prostate ever removed surgically. The only larger gland described in medical literature was that reported by Douglas,⁷ which weighed 673 Gm. In his case, however, the patient failed to survive a suprapubic cystotomy and the prostate was obtained and studied at autopsy. Freyer⁸ of England in 1908 removed a prostate weighing 529 Gm., which was the largest surgical specimen previous to the present case. His patient survived and obtained a satisfactory functional result. Freyer was accustomed to remove the largest prostates in one piece and, in another case in which the prostate was almost as big, describes graphically his struggle to encompass the entire mass and work his way down to the apex of the prostate. Such immense prostates fill the pelvis so completely that it seems to me much more simple and gentle to utilize the many natural cleavage planes between the hyperplastic spheroids and remove the mass piecemeal, as was done in the case reported. This method has the additional advantage of permitting delivery of the largest prostate through a small incision. It might be compared with Kelly's⁹ suggestion that the uterus be deliberately split in certain difficult hysterectomies.

SUMMARY

A prostate weighing 557 Gm. was removed from a patient, aged 72 (largest surgical specimen on record). This enormous prostate was almost a pound (avoirdupois) heavier than the greatest mass of tissue ever removed transurethrally up to now, even with multiple operations. Deliberate fragmentation of huge prostates is suggested as the easiest, safest method of operation.

Clinical Notes, Suggestions and New Instruments

ELECTRICALLY OPERATED BURNER AND BACTERIAL LOOP

SOL ROY ROSENTHAL, M.D., Ph.D., CHICAGO

The instrument¹ shown in the illustration will perform all the duties of a Bunsen burner and bacterial loop. It is adaptable to the private office as well as to the general laboratory.

THE APPARATUS

The apparatus consists of a removable holder and loop and a burner set in a stand. The holder and loop are held in position by two posts, which fit corresponding sockets in the stand. When in place, the chrome wire of the loop as well as the stem of the holder is automatically heated. The burner is composed

Apparatus showing removable holder and loop at right and burner at left.

of chrome wire wound on a lava spool and held at an angle to correspond with the inclination of the mouth of test tubes when passed over these coils.

METHOD OF OPERATION

For heating solutions in a test tube (urine, Benedict's solution, and the like) the latter is simply rolled over the coils. Five cubic centimeters of distilled water will boil in forty seconds. Larger amounts of water can be heated over the burner as with a flame.

For bacteriologic work the holder is withdrawn and the regular bacteriologic technic is followed, except that flaming the mouth of containers is activated by passing them close to (at 1 to 4 mm. about burner temperature is beyond 365 C., the highest register of thermometer used) or actually grazing the coils. The holder is returned to its place and is there automatically reheated.

COMMENT

By actual use in the laboratory, the instrument described has been found to qualify for the normal functions in a clinical and bacteriologic laboratory. Its advantages are:

1. It may be used more widely, since it operates from the ordinary electrical outlet.

2. It heats solutions in test tubes more gradually and thus is ideal for the ordinary urine examinations.

3. It saves time in bacteriologic work, since the loop is always ready for use (estimated at 50 per cent minimum).

4. It is silent.

1853 West Polk Street.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

ERGONOVINE

Correspondence of the Council on Pharmacy and Chemistry with Sir Henry Dale

At its annual meeting in 1936, the Council proposed the name Ergonovine as a nonproprietary designation for the new ergot alkaloid which had been termed "Ergotocin" by Kharasch, "Ergometrine" by Dudley and Moir, "Ergobasine" by Stoll, and "Ergostetrine" by Thompson. In connection with the discussion of the Council action, Sir Henry Dale of London, England, who was at that time a Corresponding Member of the Council, wrote a letter stating to the Council his opposition to the adoption of the name Ergonovine. Before the letter of Sir Henry was received the Council had adopted the name. Sir Henry was informed of this and the following correspondence between Sir Henry and the Council ensued:

Letter from Sir Henry Dale of Oct. 22, 1936:

"My attention has been so fully occupied with other matters during the past few months, that I have not found time hitherto to give to your letter of June 1st, written with the authority of the Council on Pharmacy and Chemistry, the considered reply which it required. I will ask you to convey my apologies to the Council for this unavoidable delay. From my own point of view it has a certain advantage, in enabling me to feel sure that I write in no hasty mood of resentment, but after long and careful consideration, which has not modified my view of that action by the Council which formed the subject of our correspondence. Let me, very briefly, summarize the relevant points and the principal stages of this correspondence.

"I have for a number of years been a corresponding member of the Council on Pharmacy and Chemistry. I have welcomed the implied confidence in my knowledge of and judgment in such matters as might come within the sphere of the Council's action. I have held myself ready to give to the Council, if requested, any information or opinion which might be helpful to them in the discharge of their duties. They have courteously forwarded to me, for my confidential information, the regular type-written Bulletins of their discussions and decisions. On receiving the Bulletin of February 26th of this year, I observed that notice had been given of the question whether the Council should adopt a nonproprietary name for the new ergot alkaloid. My interest in this matter might be supposed to be known to some members of the Council, and it seemed possible that they might think fit to consult me more directly upon it. To minimize the loss of time in transatlantic correspondence, I wrote spontaneously to the Council on March 16th, as soon as the matter came to my notice through the Bulletin. My association with those who had given the alkaloid the name Ergometrine made it proper that my communication, though it was as fair and judicial as I could make it, should be treated as an *ex parte* statement. I asked the Council to regard it as such, and urged them, before considering the matter, to obtain similar statements from others, who had claimed the right to name what all had admitted to be the same alkaloid. I felt bound, further, to urge, that, after carefully considering the claims of the four names already current,

1. Model by E. H. Sargent & Co. Patent applied for.

the Council should choose one of them for adoption in New and Nonofficial Remedies, and that they should not add to the existing confusion by introducing yet another name of their invention. Later I learned that the action, which I had thus deprecated in advance, had been taken by the Council on March 17th, the day after my letter was written, and long before it could reach them. It was evident that they had taken this step without communication with any of those who had made claims to the first published description of the alkaloid. Such first published description would, I think, be accepted by scientific convention in all countries, as giving the only right to bestowal on such a substance of the name to be adopted for scientific use, provided only that the name is made generally available, and not restricted in use by trade mark. I accordingly held, and still hold, the view that, in simply ignoring all such claims of prior nomenclature, and in assuming to themselves the right to impose on the medical world of America a new name of their own invention, without consultation with any of those who were properly concerned, the Council were guilty of, at least, a serious scientific discourtesy.

"In publishing their decision the Council stated that they had rejected all the names proposed by the claimants to discovery, on the ground that they were either subject to proprietary rights or objectionably suggestive of therapeutic use. Since the particular name in which I was interested, Ergometrine, could not be under any suspicion as regards proprietary protection, it had to be assumed that it was regarded by the Council as violating their rule against therapeutic suggestion. I wrote to the Council on April 20th to express my opinion of their action; and unwisely, I think, argued at some length against the decision that Ergometrine was therapeutically suggestive, and Ergonovine free from this objection. This argument has led the Council to justify their decision in detail, and has probably helped to divert their attention from the really important grounds of my objection to their action. These are two.

"1. They justify their action by the statement that 'there are almost insensible gradations between "Antirheumatic Compound," "Antifebrin" and "Ascorbic Acid."' I suppose that one must accept the Council's evidence as to the limits of their own ability to draw such a distinction; but I am bound to say that it seems clear enough to me. I am glad that the Council mention 'Ascorbic Acid,' since it provides a less complicated example of the policy, which I criticized in the case of the new ergot alkaloid. In both these cases, men of science were seeking to isolate and to identify constituents of natural materials, the existence of which was known only by specific and therapeutically important actions—in the one case, the prevention or cure of scurvy, in the other the action for which ergot had been used for centuries, viz., the stimulation of the human uterus to activity when the drug was given by the mouth. In each case, the essential discovery did not consist merely in the isolation of a hitherto unknown chemical substance, but in its experimental identification as the substance responsible for a specific action; for preventing or curing scurvy, in the one case, and for producing the traditional effect of orally administered ergot on the human uterus, in the other case. It seems to me that names such as Ascorbic Acid and Ergometrine were not only permissible, but even desirable in these circumstances, as a reminder that these substances were not merely of chemical interest, but owed their identification and their scientific interest chiefly to the specific biological activities which these names indicated. Are the Council, then, preparing to use their power of embargo against the name 'Progesterone,' accepted internationally for the pure luteal hormone by the different experts responsible for its isolation? And at what stage are we to expect the rigid application of their principles to the various antisera and vaccines, the accepted names for which flaunt, in plain English, the suggestion of their therapeutic uses, each for a particular disease or type of infection? 'Ascorbic acid' or 'Ergometrine' we are told, must be excluded on the principle which rejects 'Antirheumatic mixture'; while

'Antidysenteric serum,' to quote only one of a very long list, passes without question. If an antitoxin, identified by its specific action, were to be isolated as a chemically pure substance, would its name become improperly suggestive? It does not seem to me that the Council's action is justified by a rigid application of any intelligible principles.

"2. My most serious complaint, however, was not of the lack of consistency in the Council's action, but of their assumption of the right to make and to give effect to decisions, which cut right across the accepted rules of scientific nomenclature, without even consulting those whose proper right and interests would thus be affected. The right of a discoverer of a new substance to name it has a wider authority and recognition than any principles which the Council may lay down for themselves. I suggested, in an earlier letter, that their infringement of this right, without any kind of communication with its possessor, involved a scientific discourtesy. They reply, in effect, that it is the discoverer who is to blame for any injury or annoyance he has sustained, in that he did not obtain their approval, *before exercising his own unquestionable right*. Lest there should be any doubt about this suggestion, I quote the actual words from the letter which you wrote to me on June 1st, with the Council's express authority. 'This interpretation, or misinterpretation, of the Council's motives often could be avoided if the Council were given the opportunity to examine new names for their compliance with its rules, before these names were released to the medical public.' The subject of our correspondence was the Council's action with regard to scientific names, properly given to new substances by their discoverers. The Council suggest, as a protection for the discoverer against their invasion of his rights, that he should approach them like a manufacturer wishing to advertise a nostrum in the United States of America, and wondering how near to the wind of the Council's regulations, well known to him, he will be allowed to sail. The Council have instanced the case of Ascorbic Acid. Do they really feel entitled to assume that Professor Szent-Györgyi, or any other foreign savant, has ever heard of their rules, or even of their existence?

"It seems to me that the Council's attempt thus to extend their authority is quite intolerable, quite apart from the manner in which they exercised it. That part of their proper function which is concerned with nomenclature, deals with the misuse of names in the commercial exploitation of remedies, in the interests of particular businesses. The Council have done work of immense value in curbing the nuisance due to the misleading trick of inventing multiple trade names for a single well-known remedy; they have properly refused their approval to proprietary preparations labeled so as to indicate, not their true nature, but a therapeutic action which the proprietor wishes to suggest. But what concern have such practices with the proper naming of newly isolated pure substances—vitamins, alkaloids, or hormones—in a manner conveniently identifying them with the specific actions which led to their recognition, and which give them their chief interest? It is the attempt to act consistently, in thus applying their policy outside the proper range of their authority, that has led the Council into an attitude of such arrogant assumption, quite foreign, I am sure, to their individual natures.

"In the circumstances, there is only one proper course left to me, namely, with the greatest respect for their aims, to ask the Council to accept my resignation from the position of Corresponding Member, on account of my strong disapproval of their interpretation of their authority. In so doing I should like to thank the Council for the privilege I have had so long, of following their important activities through their confidential Bulletin. I should like to ask one parting favor, and to make one parting recommendation. I should be grateful, and I believe it would help them, by eliciting the comments of others than myself, if they thought it proper to give publicity to this letter through THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION."

Letter to Sir Henry Dale of Jan. 26, 1937:

"Your letter of October 22 in reply to the communication from the Council of June 1 was transmitted in full to the Council for its consideration.

"The Council voted (1) that your communication be submitted to the Editor of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* for his consideration with a view to publication; (2) that the following reply of the Council also be submitted to the Editor with a view to its appearance in *THE JOURNAL* with your letter of October 22. The Council further voted to await your comments on its reply before submitting both communications to the Editor of *THE JOURNAL*.

"The statement authorized by the Council as a reply to your letter of October 22 is as follows:

"Sir Henry Dale's letter concludes his correspondence with the Council regarding the naming of the new ergot alkaloid. It may be recalled that this alkaloid was discovered independently and practically concurrently by four groups of workers, and that each group had proposed a different name for this substance. The Council found that each of these names was in conflict with the published Rules of the Council, and that none of these could be accepted without nullifying the rules under which the Council had worked for these many years, and which it had applied impartially to numerous other cases. The Council therefore used the privilege which it has reserved under its published procedure and coined a name 'Ergonovine,' with the hope that this would prove acceptable to the medical public. Indeed the Council had some hope that the discoverers of the alkaloid would also see the advantages of this name. The Council did not correspond with these discoverers in advance, chiefly because it did not believe that this would do any good, since it had reason to believe that the discoverers were already familiar with these rules when they framed the conflicting names. Sir Henry Dale, who is identified with one of the groups, considers this a serious scientific discourtesy. The Council regrets that Sir Henry views its actions in this light and assures him that no discourtesy was intended. It had not occurred to any one in the Council that they would be so interpreted. Apparently it had not occurred to Sir Henry himself, in analogous cases; for instance, with Viosterol. As corresponding member of the Council, all discussions and decisions of the Council were mailed to him, just as they are to the regular members, as well as the printed Rules and Explanatory Comments in New and Nonofficial Remedies; and the Council would have been glad to receive his views on this as on all subjects. In the absence of any dissent on his part, either as to the Rule or the procedure, up to this time, his present reaction came as a distinct surprise.

"The most serious part of the letter is the assertion that the Council has no moral right to censor names applied by the discoverer. Sir Henry writes: 'The right of a discoverer of a new substance to name it has a wider authority and recognition than any principles which the Council may lay down for themselves' and 'Such first published description would, I think, be accepted by scientific convention in all countries, as giving the only right to bestowal on such a substance of the name to be adopted for scientific use, provided only that the name is made generally available, and not restricted in use by trade mark.' The last clause contradicts what precedes, or rather it indicates that Sir Henry is assuming a universal agreement with his point of view, which does not seem to exist. Such names as 'Adrenalin' and 'Insulin' have been widely accepted by scientists, although they are trademarked; and the pharmacopoeias, as well as the Council, have coined names whenever this appeared to them to be to the public interest. It may be assumed that the discoverer has also given thought to the public interest, but any one who believes that he has erred in this seems to have a moral right to endeavor to correct the error, so far as he may; and for bodies, such as the Council, which are appointed for the purpose of protecting the public interest, this right becomes a duty. The final arbiter is the public itself, especially in the case of the Council, which has considerable moral responsibility, but no power of dictating

to the public. It may indeed happen that the interests of different sections of the public differ in degree or in kind, and in such case it is possible that one name may be employed in preference by chemists, and another by physicians.

"Sir Henry feels that there is something sinister or humiliating in the Council's offer 'to examine new names for their compliance with its rules, before these names were released to the medical public.' The first words of the quotation 'This interpretation or misinterpretation of the Council's motives could often be avoided' shows that the Council had not thought of imposing humiliating conditions on the discoverer but was seeking the discoverer's cooperation in protecting the Council against the imputation of pedantry, and the public against needless polemics. At the same time, the Council feels that it would be ruinous to discriminate in the applications of its rules, and that the manufacturer has a moral right to demand that whatever rules are adopted, they be applied impartially to all the products that come to the Council. The Council doubts seriously whether scientists themselves profit in the end by a different treatment.

"Sir Henry also believes that therapeutically suggestive names are not only permissible but desirable when the substance is 'responsible for a specific action.' One difficulty in such suggestions is that of drawing a line, especially if the action of Ergometrine were considered as 'specific.' Sir Henry asks some pertinent questions about other names, which he considers inconsistent with the Council's interpretation of its rules. To these it may be replied in general that the Council has not felt called on to combat names which had become firmly established before its own Rules were adopted, and that these Rules themselves, and their interpretations, have undergone progressive development. The Council does not propose to change the name of 'morphine,' which has been in use over a hundred years; it has not even proposed to change the name of 'narcotine,' although this has become misleading; it accepted the names 'diuretin' and 'urotropin' because they were in use before the Council was established; it accepted a few other names, which are somewhat suggestive of therapeutic use, at a time when it was thought possible to draw arbitrary lines between 'more and less,' which experience has shown to be impractical; it may have accepted a name or two without recognizing their significance; but all these are not good reasons for framing and accepting new names with therapeutic suggestions.

"The answer to Sir Henry's question as to the acceptance of the name 'Antidysenteric Serum' has been tersely explained in the Rules of the Council for many years: 'The prohibition against therapeutically suggestive names is not applied to serums, vaccines and antitoxins, because the accepted nomenclature of the specific organisms used in their preparation makes this unavoidable and because self medication with them is improbable.'

"The endocrine glands, which elaborate a number of principles, do constitute a difficult problem, because the action is often the only feature by which the specific principles can be identified and differentiated, if several are present. The Council has therefore believed it advisable in the interest of avoiding confusion to accept names which imply these actions; for instance, 'androsterone,' 'estrone,' 'progesterone,' provided they are not framed as therapeutic indications. This exemption cannot be applied to the new ergot alkaloid, for Dr. Dale himself showed long ago that this is not the only ergot principle which acts on the uterus. In conclusion, it may be added that the examples which Sir Henry cites, and the difficulties which they present, are but a few of the large number which the Council endeavors to solve to the best of its ability, not by isolated instances, but with a view to the entire problem.

"The members of the Council regret that Sir Henry does not see some of these problems in the same light, especially since our ideals are fundamentally identical. Although he has ceased to be a member, we trust that he will continue to feel free at all times to discuss with the Council any matters of mutual interest."

THE RHYTHM OF HUMAN FERTILITY

Recent evidence indicating that the actual union of sperm and egg in the human species is possible only for a period of less than twenty-four hours in any menstrual cycle has stimulated tremendous interest in the possible practical applications of this apparently biologic fact. The principal corollary, according to Willson¹ in a review of this subject, is that intercourse, in order to be fertile, must take place not more than twenty-four hours preceding the actual occurrence of ovulation. This view is revolutionary and runs counter to the conclusions drawn from the more or less continuous sexual activity of man and the primates as opposed to lower animals. Furthermore, it conflicts with the previous understanding of the biologic analogies of human menstruation. Clearly, according to Willson, the biologic classification of human beings lends credence to the available clinical and laboratory evidence which points to the same midcycle timing of ovulation that exists in other primates.

The observations of Hartman, however, on the rhesus monkey, in which the time of ovulation appears to be independent of the length of the menstrual cycle, would make the unqualified acceptance of some of the practical applications of this theory rather premature at this time. At present, no practicable method or methods exist for exactly timing ovulation. Should such tests be devised, however, as Willson says, "it will require a seer to cast the horoscope of the epoch of social, economic and moral change upon the threshold of which humanity now stands!" It seems certain that the great majority of women are incapable subjectively of even approximating the time of ovulation. Until this can be done by them, or for them by appropriate laboratory tests yet to be devised, this vital date must be estimated by the physician. In the present state of knowledge it seems wise in the attempted determination of the date of ovulation to allow two days before and two days after the theoretical date.

This results in placing its occurrence somewhere in a five day period covering inclusively the twelfth to the sixteenth day before the beginning of the next menstrual period. It is necessary to add two days before the twelfth to cover the term of functional activity of the sperm and one day after the sixteenth to allow for the death of the egg. The period of possible fertility is further lengthened in most women by the fact that the menstrual cycle is likely to vary at least a few days in either direction. Thus, assuming a cycle varying between twenty-six and thirty days (actually few will be found more regular than this) the theoretical date of ovulation using the shortest cycle of twenty-six days may be estimated at the twelfth day after the day the last period began. Four additional days before this must be allowed: two for possible occurrence of early ovulation and two to cover the span of viability of the sperm. This calculation places the first day of the possible fertile period on the eighth day after menstruation. If the patient were regular with a twenty-six day cycle, this day, the eighth, would be the first of a fertile period of eight days, made up of the four days previous to the theoretical day of ovulation, the day of ovulation itself, two days after this to allow for late ovulation, and one additional day to allow for death of the egg. In view of the irregularity of the cycle, however, the difference of four in this instance is now added to the eight days originally figured to make a total of twelve, the number of days of the possible fertile period in this particular patient. Practically then, as Willson points out, the average woman with a maximum irregularity of five days who follows this method of birth control must observe a fertile period of thirteen days which, in addition to the days of menstruation, makes her incapacitated for marital relations for eighteen days in each menstrual cycle. Put in another way, this woman must be continent for about 234 days in each year, as against sixty-five days necessary for the one who is using adequate modern contraceptive measures.

No final conclusions can be drawn from the data thus far available. Willson, however, cites some personal impressions which seem noteworthy. The "safe period" he states, when determined by a competent physician or intelligent layman on reliable menstrual data, is believed to be as reliable as any other known method of contraception. It is, however, unpractical for a considerable proportion of women and unworkable for some and is therefore in no sense a uniformly satisfactory method. Because of the prolonged periods of continence necessary, it tends to destroy spontaneity in marriage to the extent that it forces sexual relations contrary to the normal physiologic tides of desire; in this respect it is antisocial and will tend to destroy rather than to promote marriage. It is obviously unsatisfactory from the standpoint of venereal prophylaxis. Until such time as its limits can be much narrowed and its exact timing more accurately determined,

1. Willson, Prentiss: Present Knowledge on the Rhythm of Human Fertility, M. Ann. District of Columbia 6: 87 (April) 1937.

it can be considered legitimately only as a method accessory and complementary to ordinary methods of contraception. The "safe period" then, used in that way, and also as a guide in the prevention or cure of sterility, is a valuable and practical addition to medical knowledge.

BENZEDRINE SULFATE "PEP PILLS"

Since the advent of ephedrine in modern therapy, a number of similar vasoconstrictors have been proposed primarily for their use in rhinology. Benzedrine, one of this group, has been accepted by the Council on Pharmacy and Chemistry.¹ Benzedrine, as well as its carbonate, differs from other vasoconstrictors which are used for this purpose in being volatile and effective by inhalation.² During the past year a nonvolatile salt of benzedrine—the sulfate—has been introduced and has been extensively exploited as a stimulant for the brain and a producer of sleeplessness. This promotion followed exaggeration in newspaper accounts of the results of experiments made with the drug in psychologic investigations.

The inhalation of benzedrine for its vasoconstrictor action occasionally resulted in sleeplessness after over-dosage. This action led to its use³ and later to the use of the sulfate⁴ orally for the treatment of narcolepsy and postencephalitic parkinsonism. The sulfate has also been used rather extensively in psychopathic institutions for its effect on fatigue and mood⁵ in certain types of mental cases. The latter studies, along with certain attempts to evaluate the mental stimulation resulting from its use in normal persons,⁶ came to the attention of the general public. Subsequently some tablets of the sulfate were used in the department of psychology at the University of Minnesota for the purpose of determining its effect in mental efficiency tests. It was noted that the drug prevented sleepiness and "pepped up" the person who was fatigued. Apparently this information was disseminated to the student body by word of mouth and the drug has been and still is being obtained by the students from drug stores

for the purpose of avoiding sleep and fatigue when preparing for examinations. Previously caffeine and coffee have been used for the purpose of staying awake during examination periods. Benzedrine sulfate, however, has a greater potential danger because it is more effective and produces many side actions which are not likely to follow the use of caffeine.

The eradication of fatigue and the stimulation of mental activity cannot be produced for any appreciable period without subsequent periods of retribution. Whipping a tired horse is an inefficient practice. Cases of collapse, fainting and insomnia have been reported to the student health physicians. Dr. Ruth Boynton⁷ issued a warning in the *Minnesota Daily* against the use of this drug by students, who refer to them as "pep pills" and, according to *Time*,⁸ deans and officials of other colleges are finding it necessary to issue similar warnings. Recently the *Minnesota Daily*,⁹ in commenting on the situation editorially, stated in part:

The growing concern of medical men over increasing use of the stimulant is reflected in an item in the current issue of *Time* magazine. There the drug is termed "poisonous," although most physicians are not willing to go so far in condemnation. All of them, however, are unanimous in condemning indiscriminate and unsupervised use.

Benzedrine differs primarily from other sympathomimetic amines that are used primarily for their vasoconstrictor actions in the extent of its ability to produce certain effects on mood and fatigue. These differences make it especially important that the drug be used only under a physician's direction. There is as little excuse for employing it to avoid fatigue and sleepiness during a temporary period of stress and strain as there is for using morphine to produce sleep after that period is over. The approaching final examinations in universities and schools suggest that physicians in a position to do so issue warnings of the danger of employing the drug in this manner. The druggist too has an opportunity to demonstrate his cooperation with the medical profession by refusing to sell the item except on prescription. Unfortunately, at one of the university cities where the drug has been obtained it has been purchased principally from the drug stores of a large national chain whose owners are apparently more interested in the immediate profit than in the ultimate effects on the purchaser. The manufacturers, on the other hand, appear to be anxious not to have the drug fall into disrepute through misuse, since it has been presented for consideration by the Council on Pharmacy and Chemistry of the American Medical Association.

Benzedrine sulfate thus becomes one more example of a drug which is useful in a limited field of therapeutics but which has been diverted to uncontrolled use by the public for related, but not similar, purposes. If the situation is to be remedied, and it certainly must be as soon as possible, the manufacturer, the druggist, the student health authorities, the college officials and

the physicians must cooperate in preventing the use of this drug by students, who through ignorance may be harming themselves, at least temporarily. It is chiefly the ignorant who try such self medication, not realizing that a drug can never substitute for knowledge or intellect. The drug is too new to pharmacology and experimental medicine to warrant any prediction as to possible permanent harm that may result from its continued misuse.

This drug is one of a group which is contraindicated in certain circulatory conditions, especially hypertension. Some persons have an idiosyncrasy to the drug, which makes its use by them inadvisable. Thus far the reports of difficulties encountered with the drug have arisen from two midwestern campuses. Physicians may well keep this drug in mind when encountering cases of fainting, exhaustion and collapse.

A PROPOSED MEDICAL EXAMINER SYSTEM FOR MICHIGAN

In 1877 Massachusetts abolished the office of coroner and replaced it with the office of medical examiner. The law authorized two full time, salaried medical examiners for Suffolk County, in which Boston is situated, and in each of the other counties as many part time examiners on a fee basis as the county commissioners might deem necessary. In such counties the number varies from one to eleven. The office is appointive, the term of service being seven years. Repeated reappointment of the medical examiners of Boston has resulted in a high type of medicolegal investigation not approached in any coroner jurisdiction. The success of the new system in Boston led to its adoption in New York City in 1918 and in Essex County (Newark), N. J., in 1927. In each of these urban centers the superiority of the medical examiner system has been amply demonstrated.

In sparsely settled rural counties the problem of the antiquated coroner's office is more difficult to solve because of the relatively small amount of work to be done. In Massachusetts outside of Suffolk County the medical examiner system is an improvement over the coroner system but still leaves much to be desired. With modern transportation facilities there is no necessity for from one to eleven medical examiners per county. In rural regions the consolidation of two or more adjoining counties into a medical examiner district under a single examiner might induce competent young physicians to enter the field of medicolegal pathology.

March 29, a bill abolishing the coroner's office and setting up an examiner system was introduced into the legislature of Michigan. The essential features of the title of this bill are:

A bill relative to investigations in certain instances of the causes of death within this state due to violence, negligence or other act or omission of a criminal nature; to provide for the taking of statements from injured persons under certain circum-

stances; to abolish the office of coroner, and to transfer the powers and duties to a state medical examiner and to county medical examiners; to create the office of state medical examiner, and provide for county medical examiners and assistants, and to prescribe their powers and duties . . .

The state medical examiner, who has no counterpart in the coroner system of any state, in addition to qualifications as to residence, profession and licensure shall "possess special training in pathology and the investigation of violent deaths." He "is authorized to incur such . . . expenses and employ such assistants as shall be necessary in carrying out the provisions of this act." A reasonable appropriation for this provision would assure the organization and maintenance of a central medicolegal laboratory or institute, which would serve the entire state through the county medical examiners. This would be the most enlightened step in this field thus far taken in this country and would go far in the development of a system of scientific medicolegal investigation. It is further provided that the state medical examiner shall supervise the county examiners, shall consult and advise with them, and may perform the duties of any county examiner who may be negligent in the performance of his work.

For each county there is to be a county medical examiner appointed for a term of three years by the board of supervisors with the approval of the state medical examiner. The county examiner must be a resident of the county for which he is appointed, or of an adjoining county. The latter provision makes it possible for a single examiner to serve two adjoining counties. This is a step toward desirable functional consolidation. The board of supervisors may also appoint, with the approval of the state medical examiner, such deputy county medical examiners as may be necessary. This would insure the proper performance of the work of populous counties. The state medical examiner may recommend to the county board of supervisors the removal of any county examiner or deputy who may fail to perform his duties properly.

County medical examiners are authorized to make the necessary examinations of the bodies of such persons "as are supposed to have come to their death by violence; without medical attendance up to a time thirty-six hours prior to the hour of death; abortion, whether self induced or otherwise; or in case any prisoner in any county or city jail shall die while so imprisoned." The county examiner is the sole judge of the necessity for postmortem examination in such cases. He may retain, for so long as may be necessary, such parts of the body as may be necessary for the detection of crime. On written order of the prosecuting attorney or attorney general or on petition of six electors of the county, the county medical examiner may investigate the death of any person whose death is believed to have occurred in the county. No dead body may be cremated without the consent of the county medical examiner. The latter official is authorized to take the statement of "any person who has been

injured by the criminal act, omission or negligence of another, and there is reason to believe that death is impending."

One of the worst features of the coroner system is the coroner's jury, as such juries are usually constituted. The Michigan act does not require a jury but makes the calling of a jury optional with the county medical examiner. The latter may issue summons; failure of attendance is subject to penalty. If it appears that death was due to the unlawful act of another, the county medical examiner shall submit his conclusions and those of the jury, if one was called, to the prosecuting attorney. Any and all medical examiners may be required to testify in behalf of the state.

In a measure so enlightened as this, it is a matter of regret to note one seriously undesirable feature. The bill provides that the state medical examiner is to be appointed by the governor for a term of four years. This carries with it the potentiality of making the medical examiner system a part of a state political machine. The terms of governor and state medical examiner should not coincide. If appointment is made by the governor, the term of the state medical examiner should be seven years, as in Massachusetts. It is to be hoped that this feature will be amended and that the measure will become a law. To Michigan would then belong the credit of being the first state to devise a statewide agency for the scientific investigation of deaths of which government must take official cognizance.

Current Comment

COLLAPSE WHILE SWIMMING

The fact that collapse and sudden death while swimming may be due to hypersensitiveness to cold has now been generally recognized. Horton and Roth¹ of the Mayo Clinic now report a further study of this phenomenon, stating that in Minnesota alone approximately 3,000 persons have drowned while swimming since 1920, and that it seems likely that at least some of them were victims of this abnormal reactivity. Physical agents such as cold, they state, probably cause increased permeability of the tissue cells and permit the release of chemical substances. As a result of cold it seems that a histamine-like substance is released and that this, in addition to producing the usual urticarial changes locally, frequently attains sufficient concentration in the general circulation to produce reactions in every way comparable to those obtained when histamine is injected into the body. Nevertheless present chemical methods are not sufficiently sensitive to allow exact quantitative estimation of the histamine-like substance in the blood and therefore corroboration awaits more exact analytic methods. Individual hypersensitiveness can be easily determined by immersion of the hand in ice water at 8 to 10 C. for five minutes. Prior to immersion, obser-

vations on the blood pressure and pulse rate are made and continued at intervals of one minute while the hand is immersed in the water and for a period of twenty minutes after removal from the water. If swelling of the hand occurs after it has been removed, the indication is that the patient is hypersensitive to cold. A systemic reaction is indicated by a drop in blood pressure, an increase in the pulse rate and flushing of the face. The Rochester investigators hold the opinion that all subjects who demonstrate a systemic reaction to this test are likely to develop symptoms of collapse if they swim in cold water. The disorder, however, is readily amenable to treatment. Systemic desensitization can be accomplished either by short immersions of the hand in cold water for one or two minutes twice a day for three or four weeks or by subcutaneous injections of 0.1 mg. or less of histamine twice daily for from two to three weeks.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Institute for Tuberculosis Workers.—An institute for tuberculosis workers will be conducted at the University of Southern California, June 14-26, under the direction of Philip P. Jacobs, Ph.D., director of publications and extension, National Tuberculosis Association. The course will be given in cooperation with the state and local tuberculosis associations. Information may be obtained from the National Tuberculosis Association, 50 West Fiftieth Street, New York.

COLORADO

Dr. Jackson Gives Memorial Lecture.—Dr. Edward Jackson, emeritus professor of ophthalmology, University of Colorado School of Medicine, Denver, delivered the third annual Phi Rho Sigma Memorial Lecture on "Light, and the Branching of Medicine," April 21. The lectureship was inaugurated by Psi chapter of Phi Rho Sigma as a memorial to deceased members of the chapter.

DISTRICT OF COLUMBIA

Short Course on Criminal Investigation.—The Institute of Criminal Science, Washington, D. C., is offering a short course in modern scientific methods of criminal investigation, June 14-July 10, at Georgetown University School of Medicine. The program includes a fifty minute lecture on "Medical Fakes and Their Detection."

GEORGIA

State Medical Election.—Dr. Grady N. Coker, Canton, was chosen president-elect of the Medical Association of Georgia at its annual meeting in Macon, May 14, and Dr. George A. Traylor, Augusta, was inducted into the presidency. Other officers elected are Drs. Charles Hall Farmer, Macon, and Hulett H. Askew, Atlanta, vice presidents. Dr. Edgar D. Shanks, Atlanta, has three more years of a five year term to serve as secretary-treasurer. The next annual meeting will be held in Augusta, May 10-13, 1938.

Society News.—The Fulton County Medical Society was addressed April 15 by Dr. George A. Williams on "The Elliott Treatment as Prophylaxis for Gonorrhea in the Female" and Mr. Earle A. Rowell, "Narcotics as Related to White Slavery, Crime, Prostitution and Medical Practice."—A recent meeting of the Georgia Medical Society was addressed in Savannah by Dr. Joseph W. White, Greenville, S. C., on "Progressive Bone Growth Deformities and Reformities."—Among other speakers, Dr. Frank K. Bolland, Atlanta, discussed surgical treatment of pulmonary tuberculosis before the Spalding County Medical Society in Griffin recently.

1. Horton, B. T., and Roth, Grace M.: Collapse While Swimming: The Most Dangerous Consequence of Hypersensitiveness to Cold, Proc. Staff Meet., Mayo Clin. 12:7 (Jan. 6) 1937.

IDAHO

Society News.—Dr. Floyd H. Jergesen, Nampa, was elected president of the Southwestern Idaho District Medical Society at a meeting in Boise, April 24, succeeding Dr. Orval F. Swindell, Boise, and Dr. Lyman F. West, Boise, was reelected secretary-treasurer. Speakers included Dr. Goodrich C. Schauffler, Portland, Ore.; Dr. Don C. Sutton, Chicago, and John A. Kostalek, Ph.D., dean of the premedical school of the University of Idaho.

ILLINOIS

State Medical Election.—Dr. Samuel E. Munson, Springfield, was chosen president-elect of the Illinois State Medical Society at its annual meeting in Peoria, May 18-20, and Dr. Rollo K. Packard, Chicago, was installed as president. Vice presidents are Drs. Everett C. Kelly, Peoria, and Thomas D. Doan, Palmyra; Drs. A. J. Markley, Garden Prairie, and Harold M. Camp, Monmouth, were reelected treasurer and secretary, respectively. The next annual meeting will be in Springfield, May 17-19, 1938.

Chicago

Personal.—The Willard Gibbs gold medal of the Chicago section of the American Chemical Society was presented, May 21, to Herbert N. McCoy, Ph.D., formerly professor of chemistry at the University of Chicago. Dr. McCoy, who is vice president and research director of the Lindsay Light Company, received his degree of doctor of philosophy at the University of Chicago in 1898. He is known for work on radioactivity.

Beaumont Collection Augmented.—Several personal items have been added to the Dr. William Beaumont collection given to the University of Chicago in 1936. The recent gifts include Dr. Beaumont's watch, his pistol with appurtenances in a mahogany case, a framed photograph of his birthplace in Lebanon, Conn., and his Masonic emblem, inscribed and dated "Plattsburgh, 1815." A Colt pistol, belonging to his son, I. G. Beaumont, was also included. The entire collection, which is the gift of the physiologist's grandson, Ethan Allen Beaumont, and his wife, of De Pere, Wis., will be on permanent display in the library of the Albert Merritt Billings Hospital of the University Clinics.

Alumni Reunions.—The annual dinner of the University of Illinois College of Medicine will be held at the Medinah Club, June 10, with the graduating class as guests of honor of the alumni and faculty. Speakers will include Arthur C. Willard, LL.D., president of the University of Illinois, and A. L. Bowen, Chicago, director of the state department of public welfare. Northwestern University Medical School held its annual reunion June 2-4. A golf tournament at the Illinois Country Club opened the session, with Dr. John F. Delph as chairman. The scientific program included lectures and demonstrations. At the annual dinner Friday evening, at which the graduating students were honor guests, the principal address was delivered by Dr. Irving S. Cutter, dean of the medical school. Dr. Howard B. Carroll, class of 1925, is secretary of the medical division, Alumni Association.

INDIANA

Dinner to Dr. Barnhill.—The Indianapolis Ophthalmological and Otolaryngological Society and the department of otolaryngology of the University of Indiana School of Medicine held a dinner meeting, April 11, in honor of Dr. John F. Barnhill, emeritus professor of surgery of the head at the school. Speakers included William Lowe Bryan, LL.D., Bloomington; Drs. Joseph C. Beck, Chicago; Harry A. Van Osdol, Indianapolis; Fred McK. Ruby, Union City; William F. Hughes, Indianapolis; Eugene G. Boss, Springfield, Mass.; Willis D. Gatch, dean of the medical school, and Mr. John Gaardsmoe, Chicago. Dr. Barnhill retired in 1927 after thirty-eight years' service as a teacher at the University of Indiana School of Medicine and its predecessor but continued his association in an advisory capacity. He was secretary of the Section on the Eye and Ear of the American Medical Association from 1901 to 1903 and chairman in 1904. He was president of the American Laryngological, Rhinological and Otolological Society in 1927.

IOWA

Outbreak of Scarlet Fever.—An outbreak of eighty-eight cases of scarlet fever, later found to be milk borne, was reported in Clarinda recently. In the beginning of the outbreak, several cases were traced to one dairy which supplied less than 10 per cent of the city's milk. Subsequent investigation, when other cases occurred, disclosed that this dairy had purchased milk from a farm which continued to sell milk although under quarantine for scarlet fever.

Fifty Years of Practice.—A dinner was given by the Scott County Medical Society in Davenport, May 4, to honor Dr. Frederick Lambach on his completion of fifty years in the practice of medicine. The guest speaker was Dr. Bert I. Beverly, Chicago, on "Behavior Problems in Children." Aged 71, Dr. Lambach graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1887. He served as coroner of Scott County for eleven years and is past president of the county medical society.

KANSAS

Weekly Cancer Clinic.—The Sedgwick County Medical Society, in cooperation with county officials, began a series of weekly diagnostic clinics on cancer, April 10, at the county hospital in Wichita. Following examination at the clinic, patients are referred to the county hospital for treatment. Dr. David W. Basham is executive officer of the clinic, to which members of the society are donating their time.

State Medical Election.—Dr. Noble E. Melencamp, Dodge City, was chosen president-elect of the Kansas Medical Society at its annual meeting in Topeka, May 4, and Dr. Jacob F. Gsell, Wichita, was inducted into the presidency. Vice presidents are Drs. George W. Davis, Ottawa, and William E. Jones, Eureka; Dr. George M. Gray, Kansas City, is treasurer, and Dr. Harry L. Chambers, Lawrence, was reelected secretary. The next annual session will be held in Wichita, May 2-5, 1938.

MAINE

Women's Field Army Aids Needy Patients.—The Women's Field Army in Maine recently voted to expend the \$13,000 collected in its membership drive in the treatment with x-rays and radium of needy patients. The money will be disbursed through a volunteer state commander with headquarters in Portland. The cost of treatment is to be determined by an advisory board.

MARYLAND

Sir Henry Dale Gives Public Lecture.—Sir Henry Dale, director, National Institute for Medical Research, London, England, delivered a public lecture, May 17, under the auspices of the Thayer Lectureship Fund, Johns Hopkins University School of Medicine, Baltimore, on "Transmission of Excitation by Acetylcholine."

Burial Permits from Adjacent States.—The Maryland Department of Health adopted a regulation, April 22, recognizing burial permits from the District of Columbia and states adjacent to Maryland. Undertakers from these states will no longer be required to obtain a second burial permit when entering Maryland. In the future, cemetery authorities in Maryland will accept, record, endorse and forward such foreign permits to the local registrar in the district of the burial, in the same manner as is prescribed by law for Maryland permits.

MASSACHUSETTS

Henry Jackson Lecture.—Dr. Lewis A. Conner, New York, delivered the annual Henry Jackson Lecture of the New England Heart Association at the Boston Medical Library, April 30; his subject was certain aspects of rheumatic fever and rheumatic heart disease.

Alumni Reunion.—The annual dinner meeting of the alumni of Boston University School of Medicine was held at the Hotel Kenmore, April 29, with Dr. Sanford B. Hooker as toastmaster. The speakers included Dr. Alexander S. Begg, dean of the school of medicine; Dr. Leroy M. S. Miner, dean of the Harvard Dental School and a member of the faculty of the school of medicine; Daniel L. Marsh, Sc.D., president of the university; Dr. Wesley T. Lee, Boston, and Anthony R. Palma, president of the graduating class. Plans for launching a campaign to raise funds for a new building equipped with modern laboratories to replace the 65 year old building on East Concord Street were discussed at the reunion.

Legislature to Study Mental Institutions.—A legislative committee of seven members was organized, April 26, to study the entire field of handling mentally diseased patients in Massachusetts, including administration of all hospitals, schools and allied institutions. Empowered to subpoena witnesses, take testimony and spend \$7,000 in its inquiry, the committee intends to study every one of the nineteen institutions in the department of mental diseases. A report must be ready December 10 for submission to the next legislature. Members of the committee are Judge John Forbes Perkins, Milton, of the Boston Juvenile Court, chairman; Erland H. Fish, Brookline, vice chairman; Judge Joseph W. Monahan, Representative Thomas P. Dillon, Dr. Lloyd Vernon Briggs, Boston, Rev. Otis F. Kelly and John M. Gray.

MICHIGAN

New Regulations for Communicable Diseases.—Botulism, chancroid and psittacosis were added to the list of reportable diseases under the revised rules and regulations for the control of communicable diseases, adopted by the state council of health recently. Streptococcal sore throat was made reportable only in epidemics. New provisions were made for the control of trachoma, which is a reportable disease, and while isolation of patients with trachoma shall be optional with the local health officer, they shall be excluded from public gatherings and not permitted to attend school.

Alumni Reunion.—The Alumni Association of Wayne University College of Medicine will hold its forty-eighth annual graduate clinic and reunion in Detroit, June 16-17. A symposium on biliary tract disease will open the program Wednesday morning at the Medical College Auditorium with Drs. Frank H. Lahey, Boston, Plinn F. Morse, Detroit, and Charles G. Johnston, Detroit, as the speakers. Other speakers will include:

Dr. James E. Davis, Malignant Tumors of the Ovary and Pathology of Puerperal Infection.

Warren O. Nelson, Ph.D., New Haven, Conn., Recent Advances in the Physiology of Reproduction.

Thomas L. Patterson, Ph.D., Demonstrations in Gastric Physiology.

A clinical program will be presented by the staff of Harper Hospital at the hospital Thursday morning, and entertainment in the afternoon will include a visit to the Parke, Davis & Co. laboratories and a boat ride, during which the annual meeting of the alumni association will be held. The annual dinner will be held in the evening at the Detroit Leland Hotel.

MINNESOTA

Reunion of Hospital Interns.—Northwestern Hospital, Minneapolis, is planning a homecoming and reunion Saturday June 19. The program will include a scientific session, luncheon, a boat ride and dinner. All former interns at the hospital are urged to communicate with Drs. Arthur E. Benjamin and William A. H. Hanson in care of the hospital, who are in charge of arrangements, so that they may be sent invitations and additional information. The hospital was established in 1882.

Society News.—At a joint meeting of the Wabasha and Winona county medical societies in Wabasha, recently, the speakers included Drs. Alfred W. Adson, Rochester, on "Problems of the Minnesota State Medical Association"; Edward A. Meyerding, St. Paul, "Our Relation to the Social Security Problem"; Albert E. Meinert, Winona, "The Nervous Patient," and Francis F. Callahan, Pokegama, "Present Trends in the Diagnosis and Treatment of Tuberculosis." Dr. Adson also discussed "Management of Essential Hypertension: Conditions and Indications for Surgical Treatment."—The Minnesota Academy of Ophthalmology and Otolaryngology was addressed, April 9, among others, by Drs. Charles E. Gurney and Henry L. Birge, Rochester, on "Experimental Study of the Fate of Free Fat Transplants" and "Pulsating Exophthalmos" respectively.

MISSOURI

Scholarships at Washington University.—Five new honor scholarships in medicine have been announced at Washington University School of Medicine, St. Louis, each to have a minimum annual stipend of \$300 and not more than \$1,000, varying with the financial state of the student who receives the award. The scholarships have been designated the Jackson Johnson Scholarships in honor of the man whose bequest to the university made them possible. The awards will be renewed for the subsequent years of the medical course, depending on the character of work done each year. The announcement from the school emphasizes that many students of unusual promise interested in medicine are in some instances unable to attend a medical school because of financial limitations and that the loss of such men to the medical profession should be avoided. The new scholarships will be made on a competitive basis to applicants of outstanding ability who possess personal qualities, habits and aptitude likely to form the basis for productive leadership in medical practice.

NEBRASKA

Society News.—Dr. Richard H. Young, Omaha, addressed the Adams County Medical Society, recently, on "The Use of Insulin Shock in the Treatment of Schizophrenia."—Dr. Alfred P. Synhorst, Grand Island, discussed hematuria at a meeting of the Nance County Medical Society in Fullerton recently.—The Omaha-Douglas County Medical Society was

addressed, April 13, by Drs. Charles F. Geschickter, Baltimore, and Francis L. Simonds, Omaha, on "Chronic Cystic Mastitis and Tumors of the Breast" and "Low Back Pain Due to Herniation or Rupture of the Inner Vertebral Disk into the Spinal Canal" respectively. Speakers at the meeting, April 27, included Bruno H. Harms, D.D.S., and Dr. John W. Duncan, who discussed cyclopropane from the standpoint of the anesthetist and surgeon respectively, and Dr. Richard H. Young, "Hypoglycemia Shock Treatment in Dementia Praecox"; Dr. George Alexander Young was the co-author of this paper.

NEW JERSEY

Personal.—Dr. William H. Vail, Newark, 92 years of age, the oldest alumnus of Blair Academy and the only surviving member of the class of 1862, attended his seventy-fifth consecutive reunion, May 8, and made an address of welcome, according to the *New York Times*. He has been a trustee of the academy fifty-one of the eighty-nine years the school has been in existence. Dr. Vail, who is retired, graduated from Columbia University College of Physicians and Surgeons in 1869.—Dr. Harrison S. Martland, Newark, has been reappointed chief county medical examiner of Essex County for a term of five years.

NEW YORK

Fifty Years as Health Officer.—Dr. Henry Charles Young was presented with an engrossed testimonial by Dr. Edward S. Godfrey Jr., Albany, state health commissioner, May 3, "in recognition of fifty years of faithful and continuous service as health officer" of Hagaman, a village in Montgomery County with a population of 867. Dr. Young graduated from Albany Medical College in 1887. He is 76 years of age.

Outbreak of Food Poisoning.—Staphylococci in the cream filling of pastry was responsible for an outbreak of fifty known cases of gastro-enteritis in Rochester and vicinity during the latter part of April, it is reported. All the patients complained of illness about two hours after eating the pastry, the purchase of which was traced to one bakery. An investigation by the city department of health showed all employees of the bakery to be free from skin lesions or other gross evidence of disease, but laboratory analyses of the cream filling revealed that staphylococci were present.

State Medical Election.—Dr. Charles H. Goodrich, Brooklyn, was elected president of the Medical Society of the State of New York at its annual meeting in Rochester, May 25, to succeed Dr. Floyd S. Winslow, Rochester. Drs. William A. Groat, Syracuse, and Arthur S. Driscoll, Staten Island, were chosen vice presidents, and Dr. Peter Irving, New York, was reelected secretary. A resolution was passed by the house of delegates directing the society to assist state authorities in the preparation and administration of motor vehicle laws to reduce the increasing fatalities from automobile accidents. The creation of two new sections on pathology and orthopedic surgery was authorized.

New York City

Conference on Tuberculosis and Public Health.—The annual conference of state and local committees on tuberculosis and public health of New York was held at the Hotel Roosevelt, May 11-13. Speakers included Drs. Wade H. Frost, Baltimore, on "Eradication of Tuberculosis"; Thorvald Madsen, Copenhagen, "Methods of Finding the Sources of Infection in Tuberculosis and Syphilis," and J. Burns Amberson Jr., New York, and Robert E. Plunkett, Albany, whose subjects were not announced.

New Home for Cancer Hospital.—A new home for the Memorial Hospital for the Treatment of Cancer and Allied Diseases will be erected on the block bounded by East Sixty-Seventh and Sixty-Eighth streets, York and First avenues, the *New York Times* reports. The building will cost approximately \$2,800,000 and provide twice as much space as is now available in the Central Park West buildings, for research and treatment. There will be accommodations for about 170 beds, with provision for expanding. It will be some twenty months before the structure is completed. The site was presented by John D. Rockefeller Jr. about a year ago, and the General Education Board provided the funds. Dr. James Ewing is director of the hospital.

Medical Relief in 1936.—The Emergency Relief Bureau, in its annual report, stated that about 900,000 persons representing 285,000 home relief cases received some type of relief during 1936, compared with 1,750,000 persons representing 440,000 cases in 1935. The Medical and Nursing Division of the bureau extended services to 130,167 home relief families;

nursing care was given to 13,955, pharmaceutical prescriptions to 68,434 and surgical or optical appliances to 18,466. The total expenditure for medical and nursing care was \$1,126,000, of which \$783,069 was spent for physicians' services, \$63,210 for nurses, \$200,073 for prescriptions, and \$79,648 for surgical and optical supplies. In 82 per cent of the families there were acute house-confining illnesses that required two or more doctors' visits. The remaining 41,584 families were either referred to hospitals or clinics after the physician's first visit or suffered from chronic illness.

NORTH CAROLINA

Society News.—Drs. Claude B. Squires and Addison G. Brenizer, Charlotte, addressed the Mecklenburg County Medical Society, March 2, on "Mandelic Acid Therapy in Urinary Infections" and "Harelip and Cleft Palate" respectively. Dr. Paul H. Ringer, Asheville, was the guest speaker at a meeting of the Eighth District Medical Society, April 8; he spoke on "Differential Diagnosis of Pulmonary Disease."

OHIO

Fifty Years of Service.—Dr. Lyman A. Brewer, chief of staff of the Mercy Hospital, Toledo, since it was founded in 1918, was guest of honor at a banquet, May 8, in recognition of his completion of fifty years in the practice of medicine and presented with an automobile, a plaque and a medal. Dr. Louis R. Effler was toastmaster at the dinner. Dr. Brewer graduated from the University of Michigan Medical School in 1887 and began practice in Toledo in 1889. He was formerly dean and professor of surgery at Toledo Medical College and assisted with the organization of Mercy Hospital in 1918. The Toledo Academy of Medicine recently made Dr. Brewer an emeritus member.

One Day Institute on Syphilis.—A one day institute on syphilis was held at the Cincinnati General Hospital, May 13. The program opened with a clinical demonstration and presentation of patients with acute syphilis. The guest speakers included Drs. Clyde L. Cummer, Cleveland, and William A. Hinton, Boston, who addressed a special meeting of the Academy of Medicine of Cincinnati in the evening on "The Role of the Private Practitioner in the Early Recognition and Treatment of Acute Syphilis and the Relations to the Local, State and National Health Organizations" and "How the State of Massachusetts Functions in the Control of Syphilis" respectively. Both speakers led a round table discussion in the afternoon and Dr. Cummer addressed a meeting at the University of Cincinnati College of Medicine.

New Professors at Ohio State.—Dr. Emmerich von Haam, assistant professor of pathology, Louisiana State University Medical Center, New Orleans, has been appointed professor and chairman of the department at Ohio State University College of Medicine, Columbus, effective July 1, and Dr. Jesse Fremont Bateman, superintendent of the Columbus State Hospital, has been appointed professor of clinical psychiatry. Dr. Carl L. Spohr has been acting chairman of the department of pathology since the death of Dr. Ernest Scott in 1934. Dr. von Haam graduated in 1926 from the Faculty of Medicine of the University of Vienna. Following a year's graduate work, he was awarded a fellowship of the Rockefeller Foundation, later receiving an appointment at the University of Arkansas as associate professor of pathology. He has been at Louisiana State University for six years. Dr. Bateman, who is 39 years of age, graduated from the University of Cincinnati College of Medicine in 1928.

PENNSYLVANIA

Dr. Gross in New Position at Polyclinic.—Dr. Herbert F. Gross has been elected to the newly created position of medical director of the Harrisburg Polyclinic Hospital. The position was created at a recent meeting of the board of directors of the hospital, at which the charter was amended and new by-laws governing the institution were adopted, it is reported. Dr. Gross is a charter member of the hospital board and staff and has served as chief surgeon since the organization of the latter.

Philadelphia

Personal.—A bronze plaque was unveiled at the Frederick Douglass Memorial Hospital, April 30, in honor of Dr. Lawrence F. Flick for his work on tuberculosis. Dr. Berton C. Truitt, chief of the medical staff, presided, and Dr. John P. Turner, head of the department of surgery, unveiled the tablet. Speakers included Judge Harry S. McDevitt, chairman of the board of directors; William C. Hunsicker, director

of public works; Ralph Senter, member of the board of directors, and Dr. Thomas S. Burwell, head of the tuberculosis department.

Anniversary of College of Physicians.—The one hundred and fiftieth anniversary of the College of Physicians of Philadelphia was observed, May 14-15. The first day Mr. Roland S. Morris, president, American Philosophical Society, spoke on "The College and Its Present Opportunities," and Dr. David Riesman, emeritus professor of clinical medicine and professor of the history of medicine, University of Pennsylvania School of Medicine, "The College, Its Library and Other Treasures." After these addresses, the building, with its reading and seminar rooms, stacks, incunabula and special collections, Mutter Museum, and special exhibits illustrating the early days of the college, was inspected. In the evening thirty-two delegates from foreign and American institutions of learning were welcomed by the president, Dr. George P. Müller. Speakers included:

Sir Henry H. Dale, director, National Institute for Medical Research, Hampstead, England, Medicine as an Experimental Science.

Dr. Hans Zinsser, professor of bacteriology and immunology, Harvard University Medical School, Boston, The Transformation of Medicine by Public Health Development.

At the fellows' banquet, Saturday, Dr. Henry E. Sigerist, William H. Welch professor of the history of medicine and director of the Institute of History of Medicine, Johns Hopkins University School of Medicine, Baltimore, discussed "The Beginnings of Scientific Societies"; Dr. Francis R. Packard, "Last Fifty Years of the College," and Dr. Müller, "The Future of the College." The College of Physicians of Philadelphia was established in 1787 and as part of its objective to advance the science of medicine awards annually the Alvarenga prize.

Pittsburgh

Society News.—At a meeting of the Allegheny County Medical Society, Pittsburgh, May 18, the speakers included Dr. Sidney M. McCurdy, Columbus, Ohio, on "The Advantages of a Medical Bureau of Economics."—Dr. Leon Herman, Philadelphia, discussed "Renal Tumors" before the Pittsburgh Medical Society at its annual meeting, May 10.

Mellon Lecture.—Edward A. Doisy, Ph.D., professor of biochemistry and director of the department, St. Louis University School of Medicine, St. Louis, gave the twentieth Mellon Lecture under the auspices of the Society for Biological Research of the University of Pittsburgh School of Medicine at the new building of the Mellon Institute for Industrial Research, May 13. Dr. Doisy's subject was "The Ovarian Follicular Hormone."

UTAH

New Department of Social Welfare.—A department of social welfare has been created at the University of Utah, Salt Lake City, to provide professional training in social case work, it is announced. Present plans call for a two year course, which may be taken by senior students. Arthur L. Beeley, Ph.D., since 1927 professor of sociology and director of the Bureau of Student Counsel at the university, has been placed in charge.

WASHINGTON

The Annual Health Conference.—The Presidents' Forum, an organization of the presidents of various women's clubs in Seattle, held its annual health conference April 26-27 under the sponsorship of the King County Medical Society. Heretofore the conference has been sponsored by the state department of health. Mrs. Walter Raymond Jones, president-elect of the woman's auxiliary of the county medical society, directed the program. Various members of the society spoke on timely subjects, and round table discussions were directed by Drs. Clarence Luverne Smith, representing pediatricians; Raymond L. Zech, the Seattle Health Council, and Donald G. Evans, state health officer.

Society News.—The King County Medical Society was addressed in Seattle, May 17, by Drs. Kenneth K. Sherwood, Kirkwood, and David Metheny, Seattle, on "Chronicity of Rheumatic Fever" and "Instrumental Perforation of the Recto-sigmoid" respectively. At a meeting, April 19, Drs. Arnold W. Hackfield and Louis H. Edmunds, both of Seattle, spoke on "Significance and Interpretation of Low Basal Metabolism Without Myxedema" and "Common Injuries to the Soft Structures About the Knees" respectively.—Dr. Karl A. Menteninger, Topeka, Kan., addressed the Pierce County Medical Society, Tacoma, recently, on "Neuropsychosis in Hypertension."—Drs. Glenn N. Rotton and Harold Frederick Thorson, Jackson, Seattle, addressed the Skagit County Medical Society, Oak Harbor, recently, on "Management of Breech" and "Simu-

sitis" respectively.—Drs. John F. Beatty and Herbert W. E. Johnson addressed the Snohomish County Medical Society, Everett, recently, on "Postoperative Lung Complications" and "Transurethral Resection" respectively.—Dr. Robert F. E. Stier, Spokane, addressed the Walla Walla Valley Medical Society, Walla Walla, recently, on "Desensitization by Oral Administration of Pollen Extracts."

WEST VIRGINIA

Refresher Courses.—The division of maternal and child hygiene of the state health department and the West Virginia Medical Association have planned a series of refresher courses in obstetrics and pediatrics during July and August. They will be held in the following towns: Charleston, Parkersburg, Huntington, Logan, Williamson, Bluefield, Welch, Beckley, Lewisburg, Elkins, Romney, Wheeling, Clarksburg, Fairmont and Morgantown. Lecturers announced in the *West Virginia Medical Journal* are Drs. James R. McCord, Atlanta; Everett D. Plass, Iowa City, and Lee Palmer, Louisville, Ky.

PHILIPPINE ISLANDS

Study of Leprosy.—A special committee on leprosy was recently formed in Manila to carry out a research project in Welfareville with children of leper parents as subjects. The study will cover research on leprosy immunization and the determination of the presence of the lepra bacillus in persons through the reaction of the bacilli to protein serum and vaccines. It will be supervised by Dr. Earl B. McKinley, dean and professor of bacteriology, George Washington University School of Medicine, Washington, D. C., and members of the newly appointed committee: Drs. Sulpicio A. Chiyuto, Manila; Cristobal Manalang, Manila; Felix Velasco, Manila; Jose N. Rodriguez, Mandaue; Casimiro B. Lara, Culion, and Herbert Windsor Wade, Culion.

CANADA

Vancouver Summer School.—The annual summer school sponsored by the Vancouver Medical Association will be held June 22-25 at the Hotel Vancouver, Vancouver. The speakers will be Drs. Leonard G. Rowntree, Philadelphia; William Boyd, Winnipeg; Paul B. Magnuson, Chicago; Harold Brunn, San Francisco, and Donald V. Trueblood, Seattle. Among the subjects to be discussed are endocrine diseases, chronic arthritis and hypertension by Dr. Rowntree, tumors of the mouth, neck and uterus by Dr. Trueblood, fractures of the femur, the forearm and the elbow by Dr. Magnuson, lung abscess, empyema, cancer of the colon and hemorrhage by Dr. Brunn, and bronchogenic carcinoma, nephritis and tumors by Dr. Boyd. Drs. Boyd, Trueblood and Bede J. M. Harrison will present a symposium on carcinoma of the breast.

Society News.—Dr. Milton H. Erickson, Eloise, Mich., addressed the Ontario Neuropsychiatric Association recently at London on "The Applications of Hypnosis to Psychiatry."—The program of the Academy of Medicine of Toronto, April 6, was arranged by the Hamilton Academy of Medicine with the following speakers: Drs. William J. L. Deadman, "Wilms' Tumors"; Otto W. Niemeier, "Some Indications for Gallbladder Surgery and the Importance of Earlier Operation," and William R. Jaffrey, "Dermatologic Neurosis." Dr. Thomas Anwyl Davies, director of the venereal disease department and lecturer at St. Thomas's Hospital, London, England, discussed "The Control of Venereal Disease in Great Britain—Statistical, Administrative and Therapeutic," before the academy, May 3.

Public Health Meeting.—The Canadian Public Health Association and the Ontario Health Officers Association will hold their annual sessions in Ottawa, June 17-19, at the Chateau Laurier. The tentative program announces the following speakers:

- Dr. Clarence E. Hill, Toronto, president, Ontario Health Officers Association, Certain Problems of Health Administration Common to All Health Officers.
- Dr. Frederick W. Jackson, Winnipeg, Manitoba, Poliomyelitis.
- E. W. McHenry, Ph.D., Toronto, Causes of Malnutrition.
- Dr. Ronald Hare, London, Puerperal Fever.
- N. L. Burnette, Ottawa, Accident Control.
- Dr. Albert Grant Fleming, Montreal, Mental Hygiene.
- Dr. Douglas V. Currey, St. Catharines, Ont., Health Administration.
- Dr. Robert E. Wodehouse, Ottawa, Ont., The Federal Department of Health.
- Dr. Malcolm R. Bow, Edmonton, Alta, president, Canadian Public Health Association (subject not announced).

At the annual dinner Friday evening, the speakers will be C. G. Power, minister of pensions and national health and honorary president of the Canadian Public Health Association, and Dr. Frank G. Boudreau, formerly of Geneva, Switzerland, director of the Milbank Fund.

GENERAL

Reunion of A. E. F. Physicians Proposed.—It has been proposed that physicians who served overseas during the World War with Evacuation Hospital No. 14 have a reunion during the annual convention of the American Legion in New York in the fall. Those who are interested are requested to communicate with Charles Meloy, Room 3050, Grand Central Terminal, New York, or Ernest O. Bianco, Elmsford, N. Y.

Executive Secretary for Academy of Pediatrics.—Dr. Thomas B. Cooley, professor of pediatrics, Wayne University School of Medicine, Detroit, has been appointed executive secretary to the council for pediatric research of the American Academy of Pediatrics. The council, which was established in 1935, includes Drs. Cooley, Kenneth D. Blackfan, chairman, and Fritz B. Talbot, of Boston; Dr. Alexis F. Hartmann, St. Louis; Dr. Irvine McQuarrie, Minneapolis, and Dr. Oscar M. Schloss, New York. Dr. Cooley is 65 years of age and a graduate of the University of Michigan School of Medicine, class of 1895. He was formerly president of the American Academy of Pediatrics.

Misrepresentation of Burial Vaults.—The Federal Trade Commission recently ordered the Cast Stone Company, Columbus, Ohio, to stop advertising that its burial vaults will harden with age and finally become adamant or of impenetrable hardness. The company agreed to stop asserting that its vaults will endure for centuries or for all time, free from the inroads of water or rodents. It will also cease implying that the material of which its vaults are made is the only material which, regardless of burial conditions, is strong and dependable enough to exclude water indefinitely, when such is not a fact. The commission's stipulation points out that vaults made of concrete are in many cases subject to the effect of and are appreciably affected by corrosion caused by the presence in the soil of alkali and other soluble chemicals.

American Association for the Study of Goiter.—The annual meeting of the American Association for the Study of Goiter will be held in Detroit, June 14-16, at the Book-Cadillac. The tentative program lists the following speakers:

- Dr. Joseph L. DeCoursey, Cincinnati, "The Goiter Problem and Abnormality: Its Relation to the Iodine Problem."
- Dr. Saul Hertz, Boston, Prognosis of the Goiter Problem.
- Dr. George W. Crile, Cleveland, Comparative Anatomy and Physiology of the Thyroid Gland.
- Drs. Walter M. Boothby and William A. Plummer, Rochester, Minn., Interpretation of Basal Metabolic Rates in the Relatively Normal Individual.
- Drs. Howard M. Clute and Fuller Albright, Boston, Management of Minor Complaints After Thyroidectomy.
- Dr. Charles W. Mayo, Rochester, Minn., Malignancy of the Thyroid: Further Observations.

"Radio Pratique" Supplants Quarantine.—Beginning February 1, the U. S. Public Health Service placed into effect the system of clearing certain passenger vessels by "radio pratique" instead of by the customary quarantine inspection. According to *Public Health Reports*, seventy-six vessels entering New York used the system 127 times in forty-six days during the period February 1-March 26. The 127 entries totaled 1,513,104 net tons and carried 42,438 passengers and 48,973 crew members. While the report covers a period of fifty-four days, there were eight days on which no eligible vessels entered the port. The seventy-six vessels, of 822,308 net tons, belonged to eighteen steamship companies under nine flags: British, American, German, French, Italian, Swedish, Dutch, Polish and Norwegian. "Radio pratique" was inaugurated to facilitate the landing of steamship passengers in the port of New York and is considered the most radical alteration of the country's sanitary defenses against the importation of foreign disease and pestilence since the first quarantine station was established in New York Harbor in 1758 (THE JOURNAL, February 6, page 484).

Certification Without Examination by Board of Internal Medicine.—Until July 1, the American Board of Internal Medicine will receive applications for certification without examination from the following groups:

- Professors and associate professors of medicine of approved schools of medicine of the United States and Canada.
- Physicians who have practiced the specialty of internal medicine for ten years and are fellows in good standing in one or more of the following special societies of internal medicine: (1) American College of Physicians, (2) Royal College of Physicians of Canada, (3) Association of American Physicians, (4) American Clinical and Climatological Association, (5) American Gastro-Enterological Association, (6) American Society for Clinical Investigation, (7) Central Society for Clinical Research.
- Physicians, members of the American Medical Association, who have practiced the specialty of internal medicine for fifteen years, and are recommended by the Executive Committee of the Section on the Practice of Medicine of the American Medical Association.

Requests for application forms should be received before July 1, at the Office of the Chairman, Dr. Walter L. Bierring, 1210, 406 Sixth Avenue, Des Moines, Iowa.

Cancer Foundation in Honor of Drs. Howell and Finney.—A foundation for the study of cancer will be created under the will of the late Dr. George Walker, head of the outpatient department of the Johns Hopkins Hospital, Baltimore, who died from cancer March 31. It will be known as the Finney-Howell Research Foundation, in honor of Dr. John M. T. Finney, emeritus professor of surgery at Johns Hopkins University Medical School, and Dr. William H. Howell, emeritus professor of physiology at the School of Hygiene and Public Health. The primary object of the foundation is to provide a series of fellowships for the study of cancer, each with an annual stipend of \$2,000, although special grants may be made to support the work done by the fellows. With no laboratory or institute of its own, the foundation will expend all the money in supporting the work of the fellows. The will places \$300,000 at the disposal of the foundation, to be expended within ten years. The fellowships will be annual appointments but may be renewed for a period of three years and may be awarded to workers in institutions in any part of the world. Members of the board of scientific directors include Drs. Finney and Howell; Philip Bard, Ph.D., Drs. Curtis F. Burnam, William A. Fisher, Wade Hampton Frost and Warren H. Lewis of Baltimore; Evarts G. Graham, St. Louis; Ernest L. Kennaway, London; Jonathan C. Meakins, Montreal, and Florence R. Sabin, New York. The financial directors of the foundation are Jesse N. Bowen, Frederick G. Boyce Jr. and Lee E. Daly, all of Baltimore.

Various Sentences for the Eyesight Swindlers.—The arrest of persons involved in the eyeswindling racket was reported in *THE JOURNAL*, Dec. 19, 1936, page 2059. The arrests were brought about by the U. S. Post Office Department. According to a recent report, Edward Robinson, alias Eddie A. Robinson, pleaded guilty in Shelby, N. C., March 15, to an indictment charging him with using the mails to defraud. He was sentenced to two years in jail on each of two counts, but the second was suspended for five years pending his good behavior. In Alexandria, Va., in the U. S. district court, Roy L. Martin, Curtis Yeager and Jack Holtkamp pleaded guilty to similar charges. Martin was sentenced to nine years and six months; Yeager's sentence of six years will begin on the completion of a sentence of five years which he is now serving in the Virginia State Penitentiary at Richmond, and Holtkamp's sentence of five years will commence at the expiration of a sentence of one year and one day, which he is now serving in the U. S. Penitentiary at Leavenworth, Kan. Frank Mackett Jr., an attorney in Milwaukee who deposited checks sent him by the swindlers for collection, remitting the proceeds less 10 per cent commission, was sentenced to seven years and to pay a fine of \$25,000. William E. Hanecy received a concurrent sentence of three years on one count and two years on another count, Lewis Levy was fined \$500 and Jerry Theeman was sentenced to four years. Other arrests, not included in the earlier list in *THE JOURNAL*, include James Henry Howard, alias Jimmy Head; William and Susie Sachs, who have been indicted in the western district of North Carolina; Raymond B. Hall, arrested at Nashville, Tenn., and removed to Norfolk, Va., for trial, and Ernest Mandell, arrested March 6 to stand trial in Milwaukee.

FOREIGN

Medal for X-Ray Research.—A David Anderson-Berry gold medal and a money prize amounting to about £100 will be awarded in July 1938 by the Royal Society of Edinburgh to the person who in the opinion of the council has produced the best recent work on the nature of x-rays in their therapeutic effect on diseases in human beings. Applications for this prize are invited. Both published and unpublished work may be submitted. Applications must be in the hands of the general secretary of the Royal Society of Edinburgh, 22 George Street, Edinburgh 2, by June 1, 1938.

Congress on Child Psychiatry.—The first International Congress on Child Psychiatry will be held in Paris July 24 to August 1, at the Maison de la chimie, 28 rue Saint-Dominique. Subjects to be discussed are neurophysiologic bases for child psychiatry, educational methods, and mental debility as a cause of infantile and juvenile delinquency. Among American physicians to take part in the discussions are Drs. Arnold L. Gesell, New Haven, Conn.; Lauretta Bender, New York; Frederick L. Patry, Albany, and Frederick Peterson, New York; Arthur H. Ruggles, Providence, R. I., and William Healy, Boston. The secretary-general is Dr. Leon Michaux, 74 Boulevard Raspail, Paris.

Foreign Meetings.—An International Congress on the Short Wave in Physics, Biology and Medicine will be held in Vienna, July 12-17. The address of the secretariat is Alser-

strasse 4, Vienna IX.—The twenty-first annual conference of the National Association for the Prevention of Tuberculosis of Great Britain will be held in Bristol, July 1-3. Information may be obtained from the Acting Secretary General, Tavistock House North, Tavistock Square, London, W. C. 1.—On the program of the International Congress on Hepatic Insufficiency to be held in Vichy, France, September 16-18, the following physicians of the United States are listed as participants: Drs. Lathan A. Crandall Jr., Chicago; Andrew C. Ivy, Chicago; Norman W. Elton, Reading, Pa., and Hyman I. Goldstein, Camden, N. J. This congress will be preceded by the second International Congress of Gastro-Enterology, in Paris, September 13-15. Those wishing to attend these congresses may receive information from Dr. Anthony Bassler, 121 East Seventy-First Street, New York.—The twenty-sixth annual meeting of the Oxford Ophthalmological Congress will be held at Keble College, Oxford, July 8-10. Among the speakers will be Dr. Bernard Samuels, New York, on "The Histopathology of Papilledema."

Deaths in Other Countries

Joseph Halban, professor of gynecology, University of Vienna, died April 23, aged 76.—Sir George W. Badgerow, London, vice president of the British Medical Association, died suddenly, May 9, in London, aged 65.—Samuel Alexander Kinnier Wilson, Croonian Lecturer, Royal College of Physicians, London, 1925; Morison Lecturer, Royal College of Physicians, Edinburgh, 1930; president, Section of Psychiatry, Royal Society of Medicine, London, 1930-1931; honorary member, neurological societies of Italy, Poland, Paris, Vienna, Philadelphia, Society of German Neurologists and Medical Society of Copenhagen and of the American Neurological Association; president, Royal Medical Society, Edinburgh, 1902-1903, died, May 12, following an operation.

Government Services

The Wellcome Prize

The Sir Henry S. Wellcome Medal and Prize of \$500 will be awarded this year for the best paper on "The Contributions of the World War to the Advancement of Medicine." Competition is open to medical department officers and former officers, acting assistant and contract surgeons of the army, navy, public health service, organized militia, U. S. Veterans' Administration, U. S. Volunteers and the reserves of the United States, commissioned medical officers of foreign military services, and all members of the association. Further information on the competition, which closes August 15, may be obtained from the secretary of the Association of Military Surgeons of the United States, Army Medical Museum, Washington, D. C.

Scientific Research Division Reorganized

Under the recent reorganization of the Scientific Research Division of the U. S. Public Health Service, effective February 1, three new divisions were established at the National Institute of Health: the division of biologic control under the direction of Sr. Surg. Walter T. Harrison; the division of public health methods, which incorporates the work of the former field office of public health methods with the work of the offices of child hygiene, milk investigations, statistical investigations and the laboratory of stream pollution investigations, under the direction of Surg. Joseph W. Mountin, and the division of industrial hygiene, which coordinates the work of the former office of industrial hygiene and the extensive laboratory studies of occupational dermatoses carried on at the National Institute of Health, under the supervision of Sr. Surg. Royd R. Sayers. The former division of bacteriology and pathology was further reorganized so that part of the division relating to bacteriology is known as the division of infectious diseases. Under the direction of Sr. Surg. Rolla E. Dyer, this division covers the field and laboratory work relating to infectious diseases, including leprosy studies, malaria investigations, the Rocky Mountain Laboratory, tuberculosis and epidemiologic studies. The division of pathology now includes the field office of cancer investigations. The former divisions of chemistry, pharmacology and zoology of the institute remain under the direction of Claude S. Hudson, Ph.D., Carl Voegtlin, Ph.D., and Maurice C. Hall, D.V.M., respectively. According to the *Health Officer*, the National Institute of Health has become, in fact, the Scientific Research Division. Asst. Surg. Gen. Lewis R. Thompson, in charge of scientific research, is now director of the institute.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 8, 1937.

Changes in the Forms of Illness

Lord Horder recently said that the expectation of life had risen by fifteen years in the past two generations and that the increase in cancer might be no more than a confirmation of that fact. Influenza was still the great plague. The decrease in tuberculosis during the past thirty years was perhaps the greatest achievement in the control of infectious diseases in this generation. Fifty years ago the large industrial cities were full of rickets. Today the disease was fast dying out. Gout had greatly declined in its most classic phases, such as acute inflammation of the big toe, but the same processes may be expressed in the circulatory apparatus. There was a considerable increase in the prevalence of diabetes. Neurasthenia was now one of the major problems of medicine, as regards both its causes and its treatment.

The Pasteurization of Milk

In the House of Lords the government announced its intention of bringing forward legislation dealing with the milk policy generally. Lord Dawson, president of the Royal College of Physicians, said that the numerous epidemics of recent years caused by infected milk made the problem urgent. He agreed that if pure milk from healthy herds could be obtained and pasteurization made unnecessary it would be ideal, but that the financial and technical difficulties were immense. He saw no other way of dealing with this vital question than a properly controlled and organized system of pasteurizing milk. The mortality from tuberculosis had declined, but there had not been the improvement in the bovine type of infection encountered with regard to the human type. What was the good, Lord Dawson asked, of spending large sums on health services while leaving this bad sore open?

Mental Disorder Following Head Injury

Before the section of psychiatry of the Royal Society of Medicine, Dr. C. P. Symonds communicated a minute study which he had made of mental disorder following head injury, based on sixteen cases in which the acute symptoms lasted from three weeks to fourteen months. These were all "closed cases." He excluded cases of compound fracture, in which the clinical picture might be complicated by laceration of the cortex or by infection. Even closed injuries might be accompanied by clinical evidence of coarse focal lesions; for instance, hemiplegia or dysphasia. These too he excluded, his object being to present what appears to be the direct effect of injury on the cerebral function as a whole.

The principal mental disorder after head injury was loss of consciousness in some degree. The qualification was necessary because confusion was apt to arise in practice as to what loss of consciousness meant. It might be argued that a man who could answer questions, such as giving his name and address, after an accident, was conscious. But if next day he had no recollection of having done so, or of the time when the accident occurred, he might be said with equal reason not to have been fully conscious. The duration of unconsciousness might be measured by that of the traumatic amnesia.

Take the common case of minor injury—so-called concussion. At the moment of the accident the clinical picture was dominated by the physical state of complete flaccid paralysis. The mental state was profound stupor, from which recovery was always gradual, through a stage of dazed bewilderment and, after this, automatism, before full consciousness returned. The initial deep stupor might be momentary, while the process of recovery was spread over a longer period. This was particu-

larly true for the phase of automatism, as in the injured football player who played to the end of the game, with subsequent amnesia. Occasionally the loss of consciousness after injury might be delayed.

After severe injuries, recovery to full consciousness might be spread over days, weeks or even months. Between these two extremes every gradation might be observed. In one case the mental disorder might be dismissed as "after-effects of concussion"; another might be dignified by the title of "acute traumatic psychosis," but Dr. Symonds believed that there was no essential difference. He considered traumatic psychosis as one disease, recognizing the predominance at one time or other of certain features—in the early stages, stupor; later, confusion; after confusion had faded into the background, amnesia for recent events, with a tendency toward confabulation.

The state of deep stupor rarely lasted more than a day or two, but it might extend to many weeks. As the patient emerged from the stupor he usually was excited, sometimes was dazed, and reacted irritably to interference. He was wet and dirty and had to be fed. Often there was delirium. This state might continue for days, weeks or even months, and there might be an occasional relapse into stupor for two or three days. Gradually conversation became possible and then were found a profound disorientation in space and time and inability to synthesize perceptual data. Memory and judgment were grossly impaired. Thought was impeded by perseveration. Disturbance of speech was conspicuous. The mood was elated and the talk resembled that of hypomania. There was a far reaching retrograde amnesia.

THE PRECIPITATION OF SPECIAL MENTAL DISORDER

Head injury might precipitate specific mental disorder—schizophrenia, paranoia or manic-depressive psychosis. This was shown in two ways. One of the symptoms of post-traumatic dementia was an exaggeration of preexisting traits. Secondly, the injury created an invalidism to which the patient reacted in terms of his mental make-up. Manic-depressive symptoms might appear before the patient recovered from the acute traumatic psychosis.

TRAUMATIC NEURASTHENIA

Why was traumatic neurasthenia more common after head injuries than after injuries of other parts? The answer was that the patients fell into three groups: 1. The accident led to the development of psychogenic states no more frequently after head than after other injuries. 2. There is a group of patients suffering from post-traumatic dementia who are apt to react with anxiety and irritability to tasks beyond their capacity. 3. A group of patients had constitutions before the accident of the depressive or anxious type. The injury precipitates an illness which, once begun, runs its own course—usually toward recovery. These patients are suffering from neurasthenia, which is traumatic in a physical rather than in a psychogenic sense.

The Overtreatment of Gonorrhea

In communications to the *Lancet*, three genito-urinary surgeons, who have had considerable experience in venereal disease clinics, maintain that gonorrhea is much overtreated. Mr. M. F. Nicholls states that acute urethritis subsides as rapidly as acute nasal catarrh with rest in bed. Custom, however, makes gonorrhea an ambulatory disease. When rest cannot be given it is illogical, he believes, to irritate the inflamed mucosa by active measures. Antiseptics cannot destroy gonococci in the urethra without damaging the mucous membrane. Yet posterior irrigation is frequently employed from the onset which unless done efficiently is dangerous. Mr. Nicholls has found it frequently responsible for spreading the infection to the posterior urethra and causing epididymo-orchitis. During the acute stage of posterior urethritis, bladder irrigation fortunately is too painful to be possible. In the chronic stages, when the posterior

urethra is already infected, filling and emptying the bladder from without with an antiseptic is better tolerated, but Mr. Nicholls thinks that it is less efficient and less safe than the passage of large quantities of urine.

Much misdirected energy, he says, is devoted to massaging the anterior urethra and prostate. This treatment seems to be carried out too early, too often and sometimes too violently. But when active inflammation has subsided and collections of mucus are present, occasional massage is probably beneficial. Employed too frequently, it produces a traumatic irritation.

The Effects on Health of the Combustion of Illuminating Gas

The Royal College of Physicians appointed a committee including Dr. W. W. Jameson, professor of public health, London University, and Sir Joseph Barcroft, F.R.S., physiologist, to investigate the effects of the combustion of gas in dwellings and particularly in flueless rooms. The report, which has just been published, shows that with properly working apparatus there is no danger to health whatever. Even in a room with a minimum air change and under conditions of gross vitiation and overheating, such as would result from a continuous gas rate of 1 cubic foot per hour for 50 cubic feet of room capacity, the maximum carbon dioxide concentration will be only about 1 per cent. A sedentary person may breathe air containing 0.02 per cent of carbon monoxide for six hours and develop only mild symptoms, such as slight headache, and there are no lasting deleterious effects. In industrial work, prolonged exposure to 0.01 per cent is permissible and does not produce harm. The committee concluded that 0.005 per cent in living rooms would be innocuous and 0.01 per cent safe. In appliances of good design, combustion is practically complete. With a maximum concentration of 1 per cent of carbon dioxide in a room the carbon monoxide would be only 0.002 and with unsatisfactory apparatus 0.01. But the normal concentration of carbon dioxide is much less than 1 per cent and the carbon monoxide correspondingly less, rarely exceeding 0.0005 per cent. There is no evidence that even the higher concentrations mentioned are injurious to health. The evidence is unconvincing as to the occurrence of any definite group of symptoms that would indicate a chronic form of carbon monoxide poisoning. This view is supported by the fact that this gas is not stored in the tissues and is therefore not a cumulative poison.

Application of Forty Hour Week to Private Hospitals

A law was passed in June 1936 according to which a salaried employee is obliged to work only forty hours a week. The application of this law to commercial organizations has taken place at a far more rapid rate than was generally thought, resulting in innumerable protests on the part of employers. March 22 a decree, as it is termed here, was issued by the president of the republic, in accordance with a motion of the minister of labor and approved by the cabinet, extending the new law to all public and private institutions engaged in the care of the sick or mentally incapacitated. The French Private Hospital Association is sending to the government the following resolution of protest against the application of the forty hour week to private institutions:

Such an application will create serious difficulties in the necessary surveillance of patients in private hospitals, and sanatoriums and will greatly increase their already existing heavy expenditures for nursing and other personnel. The present high cost of foodstuffs has already necessitated large additional expenditures, because the majority of the personnel receive their meals at these institutions.

Even before this application of the forty hour a week law, the outlay for salaries and maintenance of the personnel had already constituted 35 per cent of the total expenditures. Private patients refuse to accept an increase of more than 20 per cent in the charges for hospital care.

The allowance for care of injured veterans has not been changed since 1922, in spite of two devaluations of the French franc; the allowance for care of those injured in industrial pursuits remains the same as in 1928; finally, the allowances granted to hospitals and other institutions which receive patients covered by social insurance have not been changed in spite of the increase in premiums which all the socially insured must now pay but whose indemnities for sickness or injury are now higher than before. The closing of private hospitals and sanatoriums would throw a great many people out of work; furthermore, such institutions, in case of war, must be considered a part of the national defense. These institutions have decided therefore, in a spirit of loyalty, to attempt to apply the forty hour a week law. However, taking into consideration that employment in a hospital cannot be compared to work in a factory or office, the hospital association feels that, since hospital service is continuous, i. e., a twenty-four hour one, the hospitals have the right, in view of article 38 of the labor code, to insist on daily cessation of work of their employees, in rotation.

In consequence of a recent statement of the minister of labor, in the case of institutions in which service is continuous the working week is regarded as composed of six days, so that each employee is entitled to one day's rest every week.

Tomography in the Diagnosis of Pulmonary Lesions

The new radiographic technic of tomography will be of great aid to those interested in the diagnosis of pulmonary disorders, according to Dr. Etienne Bernard of Paris, who presented a paper at the April 7 meeting of the Académie de chirurgie. It is particularly in pulmonary tuberculosis that tomography will yield important information. For example, to detect a cavity overlooked by the usual methods of diagnosis, to be able to measure its size accurately, to locate it and to evaluate the results of an operation will be possible when this new technic is employed.

Tomography, from the Greek word "section," is needed for the following reasons: Ordinary radiography enables one to interpret the sum of all the images situated in the cone of irradiation of the luminous source. In the case of the thorax, the diameters of which are relatively large, the superposed planes form a sum of images whose analysis is often difficult and the interpretation subject to error. In addition, the shadows of the ribs obscure the normal pulmonary opacity. As a result, in certain regions the lesions can be partially or completely masked. This is particularly true wherever the ribs cross one another or the clavicle and also in the anterior and posterior costomediastinal zones. In addition, a deep seated lesion is invisible when an opacity of greater density lies in front of or behind such a lesion. Finally, a lesion is to be detected only by a difference in the degree of transparency; under ordinary conditions and in certain cases, such a difference can be insufficient, especially if the lesion is small and of slight density. The new technic renders it possible to obtain chest films in the frontal or transverse planes, free from the ordinarily superposed bone shadows. Those who have employed tomography consider it superior to stereoscopy or profile radiography. The principles of tomography are the following: As the result of the studies of Bocage (1922), Vallebona (1930), de Ziedes des Plantes (1932) and the practical adaptations of Grossmann and Chaoul (1935), the present equipment can be briefly described as consisting of an x-ray tube which, instead of being fixed, has a curvilinear movement which is coordinated with a synchronous change in position, but in the opposite direction, of the film holder. The remainder of the

technic and the interpretation of the tomographs can be read in the original of Bernard's paper (*Mémoires de l'Académie de chirurgie*; No. 11 of volume 63, meeting of April 7, 1937).

The method has been employed extensively during the past few years in Germany by Chaoul and Grossmann and by Reissner and Schmidt, in Italy by Vallebbona and in England by McDougall of Maidstone. Bernard showed a number of slides illustrating the technic and its application to the diagnosis of pulmonary lesions. The technic still needs to be improved. The supine position is required at present, which is a disadvantage in radiography of the chest.

International Congress of Industrial Medicine

The International Congress of Industrial Medicine will be held at Paris during the week beginning June 1. Prof. Victor Balthazard, head of the Medicolegal Institute here, will preside. The program includes visits to factories, excursions, entertainments at the exposition and a banquet. Among the papers, those of special interest are on the subjects of instruction in industrial medicine, treatment of workers with cardiac disease or pulmonary tuberculosis, benzene poisoning, and the modern conception of industrial medicine. Those who wish to take part in the congress are asked to write to Dr. G. Hausser, Medicolegal Institute, Paris.

Danger of Air Embolism in Thyroidectomy

The Vienna Physicians' Society recently had as a visiting lecturer Dr. Donald Guthrie of Sayre, Pa. He described the mechanism of the air embolisms that may occur in the course of a surgical intervention, especially if the thyroid is involved. Arterial embolism is more dangerous than a venous embolism, since it may lead to embolism in the brain or in the coronary arteries. In the first rank of blood vessels, predisposed to venous embolism, are those veins which are strongly intergrown with the deep cervical fascias. Fatal air embolism in man was first described in 1818, although in medieval times animals were put to death by intravenous insufflation of air. Fatalities from air embolism depend on mechanical and biologic factors; the blood becomes frothy and is forced back into the veins by the systole, a small amount of blood reaching the lungs and the left ventricle. The anemia that ensues in the region of the fourth ventricle (a vital center) causes cessation of respiration. Death occurs only if the amount of entering air exceeds a certain magnitude; the patient may be saved by timely artificial respiration. Small quantities of air cause dyspnea and a fall in blood pressure. Exophthalmic goiter patients are in greater peril if an air embolus appears than patients with other forms of thyroid disease. Diagnosis is easily established by the typical sounds that accompany entrance of air into the vascular system: a hissing sound and a "mill-wheel sound"; the latter is audible at a distance of 1 or 2 meters. Gas bubbles are often observed on the retinal blood vessels. The speaker has observed four embolic accidents, one fatal, which occurred during thyroidectomies. The best treatment is a speedy prophylactic ligature of the exposed vein; one should take care not to apply too great a number of Kocher's forceps. In operation for recurrent goiter the cicatrices are a great source of annoyance. In case of collapse the immediate indication is artificial respiration by means of oxygen and carbon dioxide, since the impairment of respiration precedes the cardiac dysfunction. Intracardial injection of a 2 per thousand solution of epinephrine can also be tried.

In the general discussion of Dr. Guthrie's paper, Professor Denk said that among 378 thyroidectomies observed by him during the past four years there had been three cases of embo-

lism, two mild and one fatal. Professor Ranzi reported similar experiences. He said that in most instances air embolism runs a favorable course. Should an embolic accident occur the patient should immediately be shifted and the field of operation covered with cloths or gauze and common salt solution. Professor Finsterer usually performs a thyroidectomy with the patient in Trendelenburg's position. He considers this the best prophylactic measure that can be taken against embolism. The drawing off of the intruding air by means of a glass tube or of a ureteral catheter advanced from the cubital vein toward the heart is recommended by many. Professor Werkgartner has gone over the necropsies for all the years since 1919 at the Institute of Legal Medicine. Since that year fifty cases of fatal embolism have been reported. Included in this number are embolic accidents connected with induced abortions and puncture wounds. In fatal cases Professor Werkgartner observed from 70 to 120 cc. of air in the right side of the heart. At necropsy it is often most difficult to determine the exact point at which the air entered. It is usually apparent that the frothy blood has been forced by the systole into the pulmonary artery and the larger veins and that relaxation of the heart has caused it to recede, so that blood no longer reaches the periphery of the lungs.

The Electrical Energies of the Organism

At the last session of the Vienna Society of Biology, Professor Dr. Keller of Prague read a highly instructive report of the micro-electrical studies of the liver and connective tissue, to which he has for many years given his attention. Keller has elicited a body of facts which constitute a notable contribution to an understanding of hepatic and connective tissue functions in their relation to metabolism. The basic fact repeatedly stressed by the investigator is this: The interrelation of the cells and the blood is governed by an electrostatic difference in potential; namely, there exists an electrical field in which the blood (serum) acts as a negative pole, and the cells of the liver or of the tissues as a positive pole. Since all nutritive substances possess a certain electrical charge, namely, are capable of being attracted or repelled by the poles according to the law of electrical attraction and repulsion, there must be a certain amount of differentiation among the nutritive substances. On the basis of this selection some substances will infiltrate the cells and others will remain in the blood. If, as is now the case, one is able to prove the validity of these theoretical assumptions by actual observations of metabolic function, it signifies a remarkable correspondence between theory and practice. The Vienna school has already evinced particular interest in this problem, as shown by practical discussions based on the work of Kaunitz, Siedek and Schober at the Eppinger clinic. Professor Keller now demonstrates these facts, using for the first time as an example the healthy liver, and shows what changes appear if the liver is diseased and the electrical tension thus diminished. Infiltration of the liver cells by water and common salt takes place and this renders the organ incapable of performing its normal tasks.

Prof. Dr. Salomon Klein and Prof. Jakob Erdheim Are Dead

The Nestor of the Vienna Faculty of Medicine, Prof. Dr. Salomon Klein-Bäringer, recently died at the age of 92 at Budapest, in which city he had resided for a short time previously. Professor Klein was a pupil of the ophthalmologist Jäger, a teacher of the classic period of the Viennese medical school. Klein's investigations of the interrelation of nerves and blood vessels of the eye, of the condition of the retina in tabes, of dementia paralytica and neuritis optica, and of cataract were of fundamental importance for the development of ophthalmology. He was a brilliant operator and teacher. He attracted to his classes a great number of foreign physicians, to whom he lectured in five different languages. Since he had been

inactive at the polyclinic for the last twenty years, the younger generation of ophthalmologists knew of him only through his past contributions.

Vienna University has suffered a great loss in the sudden death of Prof. Jakob Erdheim, who succumbed to an attack of angina pectoris at the age of 63. A pupil and assistant of Professor Dr. Weichselbaum, Erdheim was rated as one of the world's foremost pathologic anatomists. His investigations of the hypophysis and of the parathyroids have come to be of the greatest significance for present-day hormonology. Erdheim was regarded as an authority in the field of histopathology of the skeleton. In the last months of his life he dedicated himself to anatomic studies of the blood vessels. A preeminent teacher who possessed the gift of smooth and precise diction, he was an asset of the first rank to Vienna University. His lectures were perhaps the most visited in all Vienna. His pupils occupy professorial chairs the world over, in America and Asia as well as in Europe. As an international authority, he was the recipient of many high honors despite his personal modesty.

The Treatment of Vascular Lesions

Dr. Karitzky, assistant to Professor Rehn, ordinarius in surgery at Freiburg, outlined before the Freiburg Medical Society the principles advanced by Rehn on the treatment of vascular lesions. Lesions of the medium-sized and smaller arteries wherein a corresponding collateral circulation can be substituted for the normal circulation should be treated by acupression and ligation. Hematoma masses that are capable of producing a necrosis of the limb by pressure on the uninjured arteries under the rigid fascias of the lower leg ought to be removed by simultaneous wide severing of the fascias. In minor lesions of the larger, and for the nutrition more important, blood vessels, the restoration of the necessary circulation is accomplished by lateral or annular vascular sutures. The suturing, if effected within the first twenty-four hours, remains intact despite the suppuration that will appear later in the infected region of a wound. The suture brings about improved perfusion in this region and thus exercises a favorable influence on the healing of the wound. In traumatic lesions of larger arteries, the wound is covered with a free venous transplant. Plastic lesion-grafts are contraindicated only if the region of the wound is infected. In wounds from shooting, especially those inflicted by shell fragments, the suppuration of a wound leads to destruction or thrombosis of the transplant. In extensive gunshot wounds there usually is present, however, so severe a degree of destruction that even vascular plastic surgery cannot save the extremity. If, to repair a major lesion by primary suture, it is necessary to subject the lumen of the vessel to considerable traction, a later necrosis of the extremity frequently ensues despite the intact suture and permeability of the arterial lumen. Clinical observations demonstrate that for proper treatment of vascular lesions a knowledge of the physiology of the vascular system is requisite. If the technic is skilful, the results will be gratifying.

It was further observed that there is an adjustment of the venous transplant to the altered velocity within an artery. If the walls of a venous transplant are too weak, the saphenous vein dilates, elongates and serpentine itself even if it is implanted in the length corresponding to the arterial defect. This can be demonstrated by x-ray visualization. The phenomenon is explicable to be sure in terms of arterial pressure. Gradually, however, the venous wall adapts itself functionally to the arterial pressure, as histologic follow-up examinations have shown. The wall thickens (but only through the connective tissue) and becomes stronger, until finally it is commensurate with the pressure and equilibrium is then restored.

The Fight Against Cancer

Early recognition is the main problem of the anticancer campaign. Recently efforts have been made to institute annual examination of the largest possible number of women over 30 years of age for the purpose of detecting any cancerous alterations of the genitalia or of the breasts. Professor Esch, director of the women's clinic of Münster University, has just made public in the *Münchener medizinische Wochenschrift* data bearing on the anticancer campaign in Westphalia. In the year 1931 the number of cancer patients (1,024) admitted to the larger hospitals of the province was 21 per cent greater than the corresponding number (881) in 1930. In 1931 there were 386 admissions of uterine cancer cases against 296 in 1930, an increase of 32.6 per cent. The corresponding figures for breast cancer were 111 admissions in 1931 against 103 in 1930, an increase of 7.7 per cent. These increases were due to the fact that a larger number of cases in which operation could not be performed came to hospitalization. The number of admissions in 1932 was 9.1 per cent greater than that of 1931. The distribution of newly admitted cases during the three years 1930 to 1932 according to operability is given in the accompanying table. The increase in the number of operable cases in 1932 may thus be considered a noteworthy advance. In more than 10 per cent of the inoperable cases of uterine cancer, complete cure was accomplished by radiotherapy; and even in the incurable cases, important partial successes were achieved.

Esch attributes this favorable trend to better education of the public with respect to cancer. The number of persons who consulted a physician immediately after or within a month after the observation of suggestive symptoms increased by 13.4 per cent; namely, from 19.8 to 33.2 per cent of the total num-

Operability of Cancer in Newly Admitted Cases

Year	Uterine Cancer Cases		Breast Cancer Cases	
	Percentage Operable	Absolute Number of Cases	Percentage Operable	Absolute Number of Cases
1930	21.9	274	58.33	96
1931	16.53	386	56.57	111
1932	35.5	555	74.9	338

ber of patients. This increase followed the inauguration of a public propaganda campaign against cancer. Nevertheless, two thirds of the patients had been slow to consult a physician. On the basis of the foregoing data, early medical diagnosis is still lacking in a majority of cases. It was noted in particular that vaginal examination, always a necessary procedure, was frequently omitted, hemorrhages were erroneously interpreted, and the possibility of carcinoma was not given sufficient consideration in cases of younger women presenting metrorrhagia, especially if the patients appeared to be in a good state of nutrition. The illness of many women (11.6 per cent of all the patients) was often first correctly diagnosed at a late date in the clinic because of personal or domestic conditions. Some women needlessly delayed the beginning of proper attention by symptomatic treatments, which usually took the form of cauterization.

Marriages

WILLIAM DAVID MACKAY, Mount Vernon, N. Y., to Mrs. Margaret Estee Somers of Bronxville, in Miami, Fla., February 26.

MAURICE L. TOWNSEND to Miss Nell Hamlin, both of Washington, D. C., in Raleigh, N. C., February 18.

STANTON CLIFFORD LOVRE, Watertown, S. D., to Miss Frances Anderson of Lincoln, Neb., March 25.

WILLIAM BENDER MILLER to Miss Helen Jane Stambaugh, both of Harrisburg, Pa., April 17.

MERLIN TREADWELL RYMAN, Chatham, N. J., to Miss Ruth Sparks of Brooklyn, May 8.

Deaths

Way Sung New ☉ Shanghai, China; Harvard University Medical School, Boston, 1914; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; secretary of the Council of Medical Missions, and past president of the Chinese Medical Association; chairman of the administrative board of the National Anti-Tuberculosis Association of China in 1934; in charge of the department of anatomy at the Harvard Medical School of China, 1915-1916; he was an orthopedic assistant in the outpatient department of the Carney Hospital, Children's Hospital, and the Massachusetts General Hospital, Boston, 1916 and 1917; formerly was in charge of orthopedic surgery at Peiping Union Medical College; professor of orthopedic surgery, Medical Department of St. John's University; associate professor of orthopedic surgery, Woman's Christian Medical College; visiting orthopedic surgeon at the Margaret Williamson Hospital, Shanghai, and consulting orthopedic surgeon at the Soochow Hospital, Soochow; honorary superintendent of the Chinese Infectious Diseases Hospital; superintendent and chief surgeon of the Orthopedic Hospital of Shanghai, which he founded in 1928; aged 44; died, May 4.

Charles Breckenfeld Jones ☉ Sacramento, Calif.; University of California Medical Department, San Francisco, 1906; fellow of the American College of Surgeons; on the staffs of the Mercy and Sutter hospitals; surgeon to the Western Pacific Railroad Company; local surgeon to the Pacific Telephone and Telegraph Company; consulting surgeon to the Sacramento Northern Railway; aged 57; died, March 14.

George Standish Dickinson, Erie, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania and the American Gastro-Enterological Association; past president of the Erie County Medical Society; president, and for many years a member of the board of health; formerly on the staff of the Hamot Hospital; aged 66; died, March 10, of coronary thrombosis.

Charles McClure Doland ☉ Spokane, Wash.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the North Pacific Surgical Association; past president of the Spokane County Medical Society; fellow of the American College of Surgeons; veteran of the Spanish-American War; on the staff of the Sacred Heart Hospital; aged 59; died, March 13.

Archibald Magill Fauntleroy ☉ Medical Director, Captain, U. S. Navy, retired, Ossining, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1901; entered the navy in 1901 and retired in 1921; served during the World War; fellow of the American College of Surgeons; aged 60; died, April 13, at the Harkness Pavilion of the Presbyterian Medical Center, New York.

Charles Freeman Halsted, Somerville, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; University of the City of New York Medical Department, 1890; member of the Medical Society of New Jersey; member of the staff of the Somerset Hospital; aged 68; died, March 8, of pulmonary embolism and arteriosclerosis.

Millard Langfeld, Omaha; Johns Hopkins University School of Medicine, Baltimore, 1898; at one time assistant professor of medicine at the Creighton University School of Medicine; formerly city health director; author of a book entitled "Infectious and Parasitic Diseases"; aged 64; died, March 22, of essential hypertension, chronic nephritis and uremia.

Albert Harrison Hill ☉ Mifflinburg, Pa.; Medico-Chirurgical College of Philadelphia, 1901; member of the local board of health and medical inspector for the schools of Mifflinburg; aged 59; died, March 28, in the Geisinger Memorial Hospital, Danville, of perforated duodenal ulcer and subdiaphragmatic abscess.

Thomas F. Higgins, Elizabeth, N. J.; College of Physicians and Surgeons, Baltimore, 1908; member of the Medical Society of New Jersey; for many years city physician; on the staffs of the Elizabeth General Hospital, St. Elizabeth's Hospital and the Alexian Brothers' Hospital; aged 57; died, March 24, of pneumonia.

Wilder De Wolfe Hubbard, Florence, Ala.; College of Physicians and Surgeons of Chicago, 1895; member of the Medical Association of the State of Alabama; formerly secretary of the Lauderdale County Medical Society; for many years county health officer; aged 65; died, March 25, of angina pectoris.

Robin William Cummins Francis, Westerville, Ohio; Medical College of Ohio, Cincinnati, 1898; member of the Ohio State Medical Association; formerly demonstrator of anatomy at his alma mater; served during the World War; aged 66; died, March 14, in a hospital at Washington, D. C.

Hiram Clayton Finch ☉ Pulaski, Iowa; Medical College of Indiana, Indianapolis, 1881; Chicago Medical College, 1890; an Affiliate Fellow of the American Medical Association; past president of the Davis County Medical Society; aged 82; died, March 7, in Bloomfield, of cerebral hemorrhage.

Arthur Frederick Jackle, New York; University of Buffalo School of Medicine, 1907; member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Oto-Laryngology; aged 55; died, March 6, in Pasadena, Calif., of pneumonia.

Stephen Masury Gordon, Fall River, Mass.; Harvard University Medical School, Boston, 1885; member of the Massachusetts Medical Society; formerly on the staffs of the Fall River Union Hospital and the Fall River City Hospital; aged 78; died, March 20.

Waldo Milton Gaines, Sidney, Ohio; Central College of Physicians and Surgeons, Indianapolis, 1905; member of the Ohio State Medical Association; president of the medical staff of the Wilson Memorial Hospital; aged 64; died, March 16, of cerebral hemorrhage.

Robert Franklin Foster, Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1903; member of the Michigan State Medical Society; aged 66; member of the staff of the Highland Park (Mich.) Hospital, where he died in March.

Auguste Guertin, Nashua, N. H.; School of Medicine and Surgery of Montreal, 1892; member of the New Hampshire Medical Society; member of the staff of the Memorial Hospital and formerly on the staff of St. Joseph's Hospital; aged 70; died, March 7.

Ashley Darling James, Choctaw, Ala.; Medical Department of the University of Alabama, Mobile, 1901; member of the Medical Association of the State of Alabama; secretary of the Choctaw County Medical Society; aged 60; died, March 25.

Howard Conner Dunham ☉ Sulphur, Okla.; Tulane University of Louisiana School of Medicine, New Orleans, 1930; on the staffs of the Murray County Hospital and Clinic and the Soldiers Tubercular Sanatorium; aged 35; was found dead, March 15.

William Preston Hoy, Petersburg, Va.; University College of Medicine, Richmond, 1899; member of the Medical Society of Virginia; on the staff of the Petersburg Hospital; aged 61; died, March 23, in the Lankenau Hospital, Philadelphia.

John S. Hasty, Lamar, Colo.; Drake University College of Medicine, Des Moines, Iowa, 1887; St. Louis College of Physicians and Surgeons, 1891; formerly member of the state board of health; aged 76; died, March 19, in a hospital at Denver.

George Beggs Crews ☉ Denver; Chicago Medical College, 1883; at one time a medical missionary in China; formerly professor of pharmacology at the Denver and Gross College of Medicine; aged 80; died, March 11, of arteriosclerosis.

John R. Graves, Zebulon, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897; member of the Medical Association of Georgia; aged 66; died, March 30, in Chapel Hill, N. C., of cerebral hemorrhage and chronic nephritis.

Frederick Prentiss Glazier, Hudson, Mass.; Boston University School of Medicine, 1883; formerly member of the state legislature, the school committee and board of health; aged 77; died, March 23, in the Hahnemann Hospital, Worcester.

John W. Hawkey, Bloomingdale, Mich.; Medical College of Fort Wayne, Ind.; 1882; member of the Michigan State Medical Society; aged 78; died, March 16, in the City Hospital, South Haven, of carcinoma of the stomach.

William Robert Alway, Waterford, Ont., Canada; M.B., University of Toronto Faculty of Medicine, 1897; M.D., Trinity Medical College, Toronto, 1897; formerly medical health officer; aged 65; died, March 25.

Irving Lloyd Carpenter, Manchester, N. H.; Harvard University Medical School, Boston, 1890; member of the New Hampshire Medical Society; at one time city and county physician; aged 70; died, March 15.

Frederick Jerome Doherty, Medical Lake, Wash.; Trinity Medical College, Toronto, Ont., Canada, 1903; member of the staff of the State Custodial School; aged 58; died March 18, of heart disease.

David Kapp ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1906; aged 51; on the staff of the Jewish Hospital, where he died, March 19, of carcinoma of the prostate.

Charles McIntosh Burroughs, Sudbury, Ont., Canada; University of Toronto Faculty of Medicine, 1911; member of the Associated Anesthetists of the United States and Canada; aged 51; died, March 14.

John Logan Fleek, Brodhead, Wis.; Rush Medical College, Chicago, 1895; past president of the Green County Medical Society; aged 75; died, March 21, of chronic myocarditis and pulmonary tuberculosis.

Millard Francis Cupp, Clarksburg, Ind.; Medical College of Ohio, Cincinnati, 1882; member of the Indiana State Medical Association; aged 78; died, March 22, of endocarditis and arteriosclerosis.

Marvin Ward Dupree, Athens, Ala.; Medical College of Alabama, Mobile, 1903; member of the Medical Association of the State of Alabama; aged 57; died, March 13, of carcinoma of the stomach.

John O. Gaston, Rochester, Mich.; Detroit College of Medicine, 1904; at one time health officer of Accomac County, Va.; aged 58; died, March 27, of chronic myocarditis and nephritis.

Andrew Howard Fuller ☉ West Upton, Mass.; Baltimore Medical College, 1906; aged 69; died, March 13, in the Memorial Hospital, Worcester, of injuries received in an automobile accident.

Robert Lee Glascock, San Antonio, Texas; University of Louisville (Ky.) Medical Department, 1902; served during the World War; aged 68; died, March 23, of cerebral hemorrhage.

Maxwell Vidaver, New York; Bellevue Hospital Medical College, New York, 1898; aged 60; died, March 5, in the Mount Sinai Hospital, of perforated peptic ulcer and peritonitis.

Charles Edward Mackey, Boston; Tufts College Medical School, Boston, 1919; member and formerly chairman of the city school committee; aged 43; was shot and killed, March 25.

William Norman Cowles ☉ Cataumet, Mass.; Harvard University Medical School, Boston, 1887; aged 74; died suddenly, March 28, of coronary occlusion and arteriosclerosis.

Ottocar E. Kopetschny, Jersey City, N. J.; University of the City of New York Medical Department, 1886; aged 75; died, March 23, of Hodgkin's disease and arteriosclerosis.

John W. Harper, Hampton, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897; member of the Medical Association of Georgia; aged 62; died, March 22.

George Leonard Baber, Winnsboro, Texas; Atlanta College of Physicians and Surgeons, 1906; member of the State Medical Association of Texas; aged 55; died, March 3.

E. Curtis Gevedon, Grassy Creek, Ky.; Kentucky School of Medicine, Louisville, 1894; formerly member of the board of education; aged 66; died, March 14, of pneumonia.

Theophile Albert Combre, Lake Charles, La.; Meharry Medical College, Nashville, Tenn., 1917; aged 46; died in March at Kerrville, Texas, of pulmonary tuberculosis.

Israel Isaac Bernstein, New York; Baltimore Medical College, 1906; for many years on the staff of the Bronx Hospital; aged 58; died, March 9, in Miami Beach, Fla.

George Dean Ferguson, West Hartford, Conn.; University of the City of New York Medical Department, 1879; aged 80; died, March 19, of coronary thrombosis.

William Henry Doty, Sanderson, Texas; Memphis (Tenn.) Hospital Medical College, 1900; aged 66; died in March, at a hospital in Del Rio, of pneumonia.

Francis R. Lane, Sheffield, Mass.; Columbian University Medical Department, Washington, D. C., 1885; aged 78; died, March 28, of carcinoma of the prostate.

Stephen Keyes Williams, Detroit; Michigan College of Medicine and Surgery, Detroit, 1906; served during the World War; aged 56; died suddenly, March 1.

William Casey Ingram, Lanagan, Mo.; Vanderbilt University School of Medicine, Nashville, Tenn., 1893; also a druggist; aged 73; died suddenly, March 12.

David H. Wood, Coldwater, Mich.; Detroit Medical College, 1876; Civil War veteran; formerly member of the board of education; aged 91; died, March 1.

Baxter Clyde Culler, Martinsville, Va.; Tulane University of Louisiana School of Medicine, New Orleans, 1922; aged 38; died, March 15, of lobar pneumonia.

W. Jonathan Kiefer, Lebanon, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1890; aged 71; died, March 24, of cerebral hemorrhage.

Paul Francis Ela, Manchaug, Mass.; Harvard University Medical School, Boston, 1894; aged 74; died, February 19, at the Whitinsville (Mass.) Hospital.

Artemus Daniel Killian, Tuscaloosa, Ala.; University of the South Medical Department, Sewanee, Tenn., 1901; aged 65; died in March of pneumonia.

Walter Bruce Bannerman ☉ East Bridgewater, Mass.; University of the South Medical Department, Sewanee, Tenn., 1903; aged 59; died, February 27.

Henry Hanson ☉ Kirkwood, Mo.; Missouri Medical College, St. Louis, 1889; aged 79; died, March 7, in the Barnes Hospital, St. Louis, of uremia.

Paul Kase Jr., ☉ Northwood, Iowa; University of Michigan Medical School, Ann Arbor, 1931; aged 33; died suddenly, March 21, of heart disease.

Frank Philip Zeffass ☉ Hamilton, Ohio; Medical College of Ohio, Cincinnati, 1903; on the staff of the Mercy Hospital; aged 60; died, February 3.

Leonard Francis Cruse, Osage City, Mo.; Marion-Sims College of Medicine, St. Louis, 1897; aged 59; died, March 20, of cerebral hemorrhage.

George Davis, Beaufort, N. C.; Kentucky School of Medicine, Louisville, 1894; also a lawyer; aged 62; died in March of Hodgkin's disease.

Michael Evans Cole, Philadelphia, Miss.; Mississippi Medical College, Meridian, 1907; aged 54; died in March at a hospital in Meridian.

Loretta Mann Hammond, Santa Ana, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1871; aged 94; died, February 13.

Oscar L. Woodall, Iowa Park, Texas; Louisville (Ky.) Medical College, 1894; served during the World War; aged 70; died, March 4.

Henry R. Hoover, Wilson, N. C.; Baltimore Medical College, 1891; aged 76; died, March 16, of a self-inflicted bullet wound.

Jay Stiles, Lena, Ind.; Ohio Medical University, Columbus, 1898; aged 69; died, March 12, in the Putnam County Hospital, Greencastle.

Mae Sherer Harris, St. Louis; Eclectic Medical University, Kansas City, 1901; aged 68; died, March 22, of intestinal obstruction.

Francisco R. de Goenaga, San Juan, P. R.; Universidad de Santiago Facultad de Medicina, Spain, 1878; aged 80; died, March 1.

Thomas H. Diven, St. Louis; Marion-Sims College of Medicine, St. Louis, 1895; aged 67; died, March 22, of pneumonia.

Benjamin Frederick Preston, Farmington, Ga.; Eclectic Medical Institute, Cincinnati, 1908; aged 61; died, February 3.

Robert D. Flippen, Pilot Mountain, N. C.; Louisville (Ky.) Medical College, 1892; aged 65; died suddenly, March 24.

Elkanah B. Head, Franklin, Ky.; University of Nashville (Tenn.) Medical Department, 1870; aged 88; died, March 16.

Andrew Hamilton Miller, Hamilton, Ont., Canada; Trinity Medical College, Toronto, 1877; aged 88; died, February 10.

Homer Head, Dahlonega, Ga.; University of Georgia Medical Department, Augusta, 1900; aged 70; died, March 10.

Theodore E. Hoyt, Hondo, Calif.; Jefferson Medical College of Philadelphia, 1879; aged 88; died, March 22.

Alfred Jonathan Downs ☉ Los Angeles; Jefferson Medical College of Philadelphia, 1901; aged 60; died, March 12.

Henry Evans Thompson, Senecaville, Ohio; Ohio Medical University, Columbus, 1900; aged 75; died, February 7.

John Evan Engstad, Grand Forks, N. D.; Rush Medical College, Chicago, 1885; aged 78; died, February 19.

James E. Gray, Danville, Ohio; Illinois Medical College, Chicago, 1898; aged 72; was found dead, March 4.

Warren Riley Stateler, Dupont, Ohio; Kentucky School of Medicine, Louisville, 1893; aged 72; died, March 2.

Howell Cobb Strickland, Gillsville, Ga.; Atlanta Medical College, 1890; aged 76; died, February 26.

Samuel C. Balch, Etiwanda, Calif. (licensed in Illinois in 1877); aged 86; died, March 11.

B. N. Spears, Junction City, Ark. (licensed in Arkansas in 1903); died, February 20.

Bureau of Investigation

SEX AND GLAND REJUVENATORS

Postmaster General Clamps Down on Mail Order Frauds

The United States Post Office Department has recently clamped down on several concerns exploiting gland remedies of the sexual rejuvenation type.

BERLIN PRODUCTS COMPANY

On March 22, 1937, the Acting Postmaster General, Harlee Branch, issued a Post Office fraud order against the Berlin Products Company, the Atlas Products Company, the Atlas Products, and their officers and agents, of Chicago.

According to the fraud order, a Mr. Charles S. Thompson sold through the mails preparations called "Prescription No. 25" and "Prescription No. 40," for sexual deficiencies and allied conditions in men and women. The enterprise was started in August 1936 by J. Walker Jones, who, after two weeks' operation, sold it to the present proprietor.

Victims for the nostrums were obtained by newspaper and periodical advertisements. One such advertisement read:

"FOR MEN AND WOMEN MAKE THIS TEST AT OUR RISK

"Don't feel old. Be young at 60. Help your glands by using famous doctor's own guaranteed private prescriptions of proven merit . . . Prescription No. 25 for men, and prescription No. 40 for women. These prescriptions assist nature in restoring the prostate, ovaries and other glands of the body to normal activity. Harmless and effective. Price \$1.00, super strength, \$4.00. If C. O. D., postage extra.

MONEY-BACK-GUARANTEE

After 6 days trial, if you are not satisfied, return the unused portion of the medicine and your money will be returned. You be the judge.

BERLIN PRODUCTS CO., 454 E. 42nd St., Dept. 4, Chicago, Ill."

The promoter advised the post office inspector who investigated the case that the formula for the preparations is as follows:

Prescription No. 25, Orchic Substance, prostate substance, ext. nux vomica, ext. yohimbin, and zinc phosphide.

Prescription No. 40, Ovarian substance and pituitary substance.

The therapeutic effects of the active ingredients are well known to the medical profession. Substances such as are contained in Prescription No. 25 have no value in restoring the prostate to normal or rejuvenating sexual vigor. The claims made for Prescription No. 40 for women were also held to be false.

BIO-CHEMICAL LABORATORIES, LTD.

The Bio-Chemical Laboratories, Ltd., the Laboratori Biochimici, S. A., the Laboratories Biochimiques, S. A., and the Biochemische Laboratorien, A. G., of Locarno and Melano, Switzerland, had the United States mails closed to them on April 6, 1937, for selling through the United States mails a fraudulent "gland treatment" called "Bulltone," a "Sexual and Nerve Tonic for men."

According to the fraud order, a chemical analysis of the preparation showed that it consisted "essentially of animal or glandular matter, kola nut and yohimbin."

Yohimbin at one time was thought to have value in sexual impotence but has long since been discarded by the medical profession.

The post office authorities held that it was false to claim that Bulltone was a proper treatment for "all stages and forms of sexual debility, nervous derangements, general weakness, loss of memory, increased liability to tiredness, neurasthenia."

ZION HOLY SPIRITUAL MISSION

On April 7, 1937, the Postmaster General closed the mails to the Zion Holy Spiritual Mission; Zion Holy Spiritual Laboratories; Zion Holy Spiritual Mission Laboratory; Rev. E. N. French, D.D.; Rev. E. N. French, D.D., Manager; Rev. Dr. E. N. French, Spiritual Adviser; Rev. Dr. E. N. French, Spiritual Adviser and Bishop; Zion Holy Spiritual Mission Distributing Auxiliary, and their officers and agents as such.

The "Rev. E. N. French, D.D.," a thirty-five year old British West Indian Negro, operated a combination mail order business and a so-called "mission" in Chicago. According to the

post office report, 75 per cent of his mail order business consisted of the sale of a preparation called "Bry-o-lyn" for "blood trouble," lost manhood and various other diseases and ailments. The versatile Rev. French also sold a "kidney and bladder treatment," a "bowel" preparation, an alleged remedy for piles, a corn treatment, and various talismanic seals.

Bry-o-lyn, the leader of the French preparations, was analyzed by the Food and Drug Administration and shown to contain "iron, emodin and small quantities of ammonium, magnesium, sodium, potassium sulfate and chloride." It was essentially an iron solution containing saline laxatives and was, of course, wholly worthless for the diseases and ailments for which it was recommended.

The kidney and bladder nostrum was found to contain copaiba, potassium nitrate, emodin, magnesium, iron sulfate and carbonate. The pile medicine consisted of a white salve containing a small percentage of calomel, phenol and boric acid.

French, the post office evidence shows, is not a physician, chemist or pharmacist; neither had he ever been ordained as a minister.

WEST COAST SPECIALTIES COMPANY

The West Coast Specialties Company, Pacific Coast Specialties Company, and their officers and agents as such at Portland, Ore., were found by Acting Postmaster General Howes on April 27, 1937, to be conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises.

According to the post office report, the West Coast Specialties Company and the Pacific Coast Specialties Company are names used by a J. E. Tryzelaar in the sale through the mails of a "marvelous secret." The "secret" was represented as enabling the possessors to retain their youthful appearance and vigor regardless of age and to overcome various diseases and ailments incident to advancing years.

Patronage was attracted through advertisements of the "Be Young at 60" type. Among other representations was the "gag" used by practically all food faddists that the ordinary diet lacks certain vital food elements. "Absence of this unusual food element in the daily diet is the chief cause of premature old age, graying or falling hair . . . mental depression . . . hardening of the arteries and high blood pressure."

The gullible who made remittances received a single, letter-size, printed sheet containing the "Vital Health Secret." The secret seemed to be that ". . . iodine is essential for the health of man," and some rambling phrases purporting to show the incidence of iodine deficiency and goiter.

Iodine, therefore, in varying doses, was recommended as an old age preventer and as a means of eliminating gray or falling hair, wrinkles, facial lines, sagging muscles in the face and neck, pyorrhea, tooth decay, poor circulation and various other ailments. The medical evidence introduced by the post office authorities failed to concur that iodine possessed such marvelous therapeutic properties, and the Postmaster General closed the mails to the aforementioned concerns and parties.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Golden Brown Ointment.—McKesson-Van Fleet-Ellis Corp., Memphis. Composition: Essentially petrolatum with 10 per cent of mercuric oxide. For eczema, rash, pimples, skin discolorations, etc. Fraudulent therapeutic claims.—[N. J. 21978; September, 1934.]

Men-tho-lo.—Leighton Supply Co., Pittsburgh. Composition: Essentially menthol and wintergreen in a mixture of petrolatum, paraffin, starch and water. For toothache, asthma, rheumatism, catarrh, piles, etc. Fraudulent therapeutic claims.—[N. J. 24034; November, 1935.]

Ray-X.—Ray-X Corp., no address given. Composition: A water containing minute proportions of salts in solution. Cure-all. Fraudulent therapeutic claims.—[N. J. 24017; November, 1935.]

Correspondence

"MACHINE FEVER" IN SYPHILIS

To the Editor:—In the May issue of the *Reader's Digest* is a condensation of an article entitled "Machine Fever," by Paul de Kruif, which appeared originally in the *Country Gentleman* for April. The condensed article in the *Reader's Digest* contains one sentence at the beginning of the second paragraph on page 109 which reads "No longer, then, need a victim of early syphilis come once a week for almost two years for treatment with the standard arsenic and bismuth dosage." I must confess that I am disturbed by the implications of this detached sentence, particularly since it bears on certain experimental studies which we have carried out at the Kettering Institute for Medical Research in Dayton.

In the original article by de Kruif, he described accurately and in some detail the character and extent of the experimental studies on the treatment of early syphilis with artificial fever therapy combined with chemotherapy. De Kruif stated that these experiments had extended only over four years and had involved only thirty-two patients. To quote from the original article in the *Country Gentleman*: "All these thirty-two have been given the now safe, practical machine fever; and at the same time small, safe shots of arsenic and bismuth drugs are injected to reinforce the fever's power. This test has been in progress only four years; it is still strictly experimental; and it is true that syphilis is of all plagues the longest, sneakingest, most treacherous. . . ."

In our publications in medical literature we have emphasized repeatedly the purely experimental character of the application of artificial fever therapy as an adjunct to chemical therapy in the treatment of early syphilis. While there is no longer any valid reason to doubt the efficacy of fever therapy in the treatment of syphilis of the central nervous system, it would be extremely illogical and indiscreet to intimate at this preliminary stage of the experiment that this method of treatment should be regarded as a tried and proved procedure for the treatment of early syphilis. The standard schema of continuous chemical treatment as outlined by Surgeon General Thomas Parran and the other members of the Cooperative Clinical Group of the U. S. Public Health Service provides, without question, the best method for the mass attack on the enormous number of cases of early syphilis which occur each year in this country. Furthermore, the remarkable results which have been achieved in the nation-wide programs for the eradication of syphilis in Denmark, Sweden and Great Britain leave little doubt as to the efficacy of controlled and adequate chemical therapy in the mass-management of the disease.

Even in the few cases of early syphilis in which artificial fever therapy has been combined with chemotherapy the patients have received injections of arsenic and bismuth preparations for several months. It will require many more years of diligent experimentation before the combined artificial fever-chemical method of treatment of early syphilis is established as sound practice or rejected. The constant development of simpler and safer methods for the production of artificial fever should stimulate vigorous inquiry of the possibility that the time, effort and expense involved in the adequate therapy of early syphilis may be greatly lessened. Such studies should be restricted to those large clinics in which adequately trained personnel may engage in long-term, controlled experiments.

There are no tried and proved "short cuts" to the treatment of syphilis. To create such an impression would be to declare a Roman holiday for the charlatan.

WALTER M. SIMPSON, M.D., Dayton, Ohio.
Director, Kettering Institute for Medical
Research, Miami Valley Hospital.

EDUCATIONAL LANGUAGE TEST FOR PHYSICIANS

To the Editor:—In THE JOURNAL, Oct. 3, 1936, in a communication entitled "Vocabulary of Physicians and Aptitude Tests," there is a list of words from Garrison's History of Medicine used in the aptitude tests.

I hate to admit it but there were many that I had never seen before, so I began looking the definitions up in Funk and Wagnalls, Webster's latest unabridged Dictionary, and Dorland's seventeenth edition of the Medical Dictionary, 1936, and was unable to find definitions for six of the 131 words.

I presume they are scientific words occurring in biology or botany, but certainly they should be in one of these three dictionaries. Would you kindly tell me the definition of the following, or where to find them: farago, marano, mascaron, paracutic, vao and espalier?

It would be interesting to find how many physicians many years in practice could define these words.

C. C. OWEN, M.D., San Bernardino, Calif.

COMMENT.—Farago: A Spanish word equivalent to fardo, which means a bundle.

Marano: A Jew or a Moor who, during the persecution by the Spanish Inquisition, publicly professed Christianity but privately adhered to his own religion (Standard Dictionary).

Mascaron: A grotesque mask (Standard Dictionary).

Paracutic: Probably an adjective from the noun paracusis, in which case it would refer to any perversion of hearing.

Vao: An arrow poison from the United States of Colombia, containing corrovaline; supposed to be adulterated corroval (Foster's Medical Dictionary).

Espalier: A trellis on which to train the branches of fruit trees (Standard Dictionary).—Ed.

ORTHOSTATIC HYPOTENSION

To the Editor:—There is an importance in the article on "Orthostatic Hypotension: The Treatment of Two Cases with Benzedrine Sulfate," by Perk Lee Davis and Margaret Shumway-Davis, in THE JOURNAL, April 10, page 1247, which should be recognized and applauded. This importance lies in the fact that the authors have used a comparatively unknown function of the circulation to determine the effect of a drug. This function of the circulation is its "gravity resisting ability." The symptom that reveals its weakness is "postural" or "orthostatic hypotension." This is measured by comparing the blood pressure lying down with the blood pressure while standing. Postural or orthostatic hypotension (first called blood ptosis) is measured by the amount of fall of blood pressure on standing. The systolic pressure moves more than the diastolic. Differences may amount to as much as from 80 to 100 mm. on standing, and in postural hypotension there may be high blood pressure lying down, low blood pressure standing up.

Postural hypotension has been noted by Ghrist and Brown (*Am. J. M. Sc.* 175:336 [March] 1928), by Bradbury and Eggleston (*Am. Heart J.* 1:73, 1926), Sewall (*Am. J. M. Sc.* 1:491 [April] 1916) and perhaps earliest in America by me (*M. News* 87:529 [Sept. 16] 1905; *New York M. J.*, November, 1913; *Am. J. M. Sc.* 160:721 [Nov.] 1920). Bradbury and Eggleston considered postural hypotension an illness and sought remedies, finding none that would adequately affect the symptom. Ghrist and Brown, at the Mayo Clinic, reported successful treatment by ephedrine sulfate. I have found that digitalis and squill will favorably affect some cases, notably chronic hypotension (Mosenthal, H. O.: *Diagnosis and Treatment of Variations in Blood Pressure*, Oxford University Press, p. 60. Crampton, C. W.: *New York State J. Med.* 36:1087 [Aug. 1] 1936).

The obvious result of these observations has been that certain drugs—digitalis, squill, ephedrine—will favorably affect

postural hypotension. The Davises have added benzedrine sulfate. In this use of postural hypotension as a test of the efficiency of the drug they have added an item of importance to the careful work in clinical observations in the effect of benzedrine sulfate by Wilbur, MacLean and Allen (*Proc. Staff Meet., Mayo Clin.* 12:97 [Feb. 17] 1937), who as yet have not reported on the effect on this significant symptom, which is now, I understand, under way at Rochester. The less obvious but most important fact is revealed that there is now a method of finding out more about the effect of drugs than before; they can be calibrated as to their effect on a factor of circulatory efficiency essential to life and, shown by postural hypotension, this is different from pulse rates and all blood pressures considered singly.

I have repeatedly urged the use of this symptom for pharmacologic assay and welcome the work of the Davises. Let others follow.

C. WARD CRAMPTON, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

WAS A DIAGNOSIS OF SYPHILIS JUSTIFIED?

To the Editor:—In December 1930, on the basis of a single four plus Kahn reaction, a diagnosis of syphilis was made in the case of a white man, aged 20, single. There was no history of exposure or evidence of a primary lesion. No familial history or congenital stigmas of syphilis could be ascertained. The patient has continued well and healthy on active duty in military service. His conduct is exemplary. Treatment to date has consisted of forty-nine injections of nearsphenamine, fifty-five of bismuth compounds, seventy mercury injections or inunctions, and an indeterminate amount of mixed treatment and potassium iodide by mouth. Twenty-five serologic tests have been performed (Kahn and Wassermann). These have ranged the scale from 0 to 4 plus with no apparent relation to treatment. Two spinal fluid examinations have been negative. The Bureau of Medicine and Surgery, United States Navy, disapproves establishing a diagnosis of syphilis by means of serologic positivity alone. The institution of treatment clouds the issue as to the true diagnosis ever being definitely known. False positive serologic results do occur. Within the past two years I have seen them reported in cases of influenza, malaria and vaccinia. Syphilis has been ruled out in these cases by the prolonged observation of various medical officers. The serologic reaction returned to negative without treatment. The spinal fluids were normal. The person involved craves assurance that he is nonsyphilitic. In view of the fluctuating serologic reaction I have hesitated, though it would appear that adequate treatment has been given. My advice has been to watch and wait. I would greatly appreciate your opinion as to the validity of the diagnosis, whether further treatment is indicated and how you would advise this patient.

M.D., Florida.

ANSWER:—This inquiry involves two points for discussion: (1) the issue of nonspecific or falsely positive serologic tests and (2) the question of latent syphilis. In regard to the first point, since the advent of the flocculation tests clinicians have been confronted with "weak positive" reports in patients who have neither signs nor symptoms nor a history of syphilis. This type of report is encountered in patients who have systemic disease not of syphilitic nature as well as in those who are apparently perfectly well. The majority of serologists are loath to accept the idea that such reports may be falsely positive, and many clinicians will not accept such reports as diagnostic of syphilis. In a sense both the clinician and the serologist are right because these "weak positive" reports are encountered in persons known to have syphilis and on the other hand they have also been reported during the menstrual period, in association with endocarditis, cutaneous and glandular tuberculosis, lymphoblastoma, and during numerous febrile states. The interpretation of these reports, especially when numerous tests are done with variations in the degree of positivity, is difficult. It is suggested that, when inconclusive reports are obtained from one laboratory in this way, a specimen of blood be drawn not sooner than eight hours after the patient has eaten and divided so that it can be placed in two or three test tubes and sent to two or three different laboratories for examination. This permits all the laboratories to examine the same specimen. The majority of these reports should be accepted as authentic.

The diagnosis of syphilis was accepted and treatment was given in 1930, and the patient is now clinically negative; the spinal fluid is negative but there are variations in the serologic report. If we accept the original diagnosis as correct, the patient is in the latent phase of syphilis and should be treated with two courses of bismuth compounds a year for several years to come. It is not possible from the data furnished to determine accurately now whether the patient ever had syphilis, as the facts that he is clinically negative and his present physician feels that the reports are false positives are not sufficient reasons to discard the original diagnosis as made in 1930. In fact, the responsibility of the diagnosis rests on the physician who accepted the report and started treatment, and there is not sufficient evidence available now to say that he was in error.

The opinion expressed that a diagnosis of syphilis should not be made on the basis of positive serologic tests alone is not warranted if for no other reason than the fact that patients in whom the diagnosis of syphilis was supported by clinical manifestations may develop latency and remain serologically positive indefinitely. When such cases are encountered for the first time, the serologic evidence confirmed by repeated tests in an accredited laboratory is the only basis for the diagnosis of syphilis.

It is readily understood why the inquirer is loath to accept the diagnosis of syphilis now and why he believes the reports are not authentic. Similar problems are encountered frequently by syphilologists, and in the future, as the serologic tests become more sensitive, more confusion will be created in the minds of physicians who encounter patients with syphilis occasionally because more falsely positive tests will be reported. Sometimes our sympathy for the individual involved will sway our judgment and lead to the ignoring of an authentic positive test, an offense as serious as treating an individual because of a falsely positive test.

Accordingly, it would seem wise to accept the diagnosis as made in 1930 and to continue with bismuth treatment and observation. Further repetition of the spinal fluid test is not necessary. Following an observation period of three years, if no clinical symptoms appear, the patient may marry if he so wishes.

LYMPHEDEMA OF LEG

To the Editor:—A white woman, aged 28, came to me complaining of swelling of her right leg from the ankle to approximately 4 inches below the knee. In April of this year she had erysipelas of this area, which was treated by violet ray and in due time disappeared. However, after the erysipelas was apparently cured she began to notice that the leg would swell, especially with standing or walking. After a night's rest in bed the leg would be of normal size, but within three hours after she resumed activity the swelling would reappear. The remainder of the physical examination was negative and the past history was negative. She has used hot epsom salt packs to this area, infra-red radiation, ultra-violet rays and high voltage roentgen therapy. She has had no treatment for three weeks but still complains of and exhibits swelling of this leg. Can you suggest any medication or treatment that I might give her to relieve this condition? Please omit name.

M.D., Ohio.

ANSWER:—Apparently the patient had acute lymphangitis and cellulitis in April, which was followed by lymphedema. Acute lymphangitis and cellulitis produce lymphedema by effecting thrombosis of the lymph vessels, which produces lymph stasis, which in turn causes an overgrowth of connective tissue and obstruction of the lymphatics. While one cannot determine the etiology of the episode of acute inflammation from the history of this case, one should always suspect trichophytosis, as this condition is responsible for single or recurrent episodes of acute lymphangitis and cellulitis of the lower extremities in a considerable number of cases.

The treatment consists in active treatment of trichophytosis, if this condition is present, and prevention of the edema by adequate bandaging. An important first step is elevation of the extremity until as much as possible of the lymph has been removed from the extremity. Cloth bandages are of little or no value; the support which they give is of little value. Elastic stockings are unsatisfactory in many instances, for the same reason; they tend to stretch and lose their elasticity. Adhesive bandages are somewhat more efficient than the previously mentioned supports. The entire criteria for establishing the value of any type of support is control of edema; a support that does not prevent swelling, when the patient is active, is valueless; one that prevents swelling is adequate. A pure rubber roller bandage, 3 inches wide and 15 feet long, is preferable. Of the three weights available, the proper one prescribed for any specific patient depends on the difficulty in controlling the edema. Ordinarily, the bandage is applied over a lisle stocking, beginning by making two turns about the foot, two figure-eight turns about the ankle, and progressing up the extremity

to the knee. The toes and part of the heel are left exposed. The bandage should be removed and applied in the same manner each time, as it becomes shaped to the extremity on repeated use. If it is applied too tightly, the toes become discolored, cold and numb. If it is applied too loosely, edema results. Patients soon become adept at bandaging their legs efficiently. The bandage should be removed at midday and reapplied over a dry stocking after the patient has rested for an hour. The same procedure is repeated at night if the patient is active. If he remains home, he may remove the bandage and elevate the leg, while sitting. Patients object to wearing the bandages because of the inconvenience in applying them repeatedly, the slight discomfort, and their unsightly appearance. This is particularly true of women, who object to the appearance of the bandaged limb. Frequently a well fitting elastic stocking may be used for "dress" occasions, and the use of the heavier rubber bandage may be reserved for ordinary activity. It is well to point out to women that the lymphedematous leg has an abnormal appearance which the bandage increases but little, and to emphasize that uncontrolled edema almost invariably causes a gradual increase in the size of the limb. Information regarding how long the bandage should be worn is not available; in some instances it must be used indefinitely; in others, improvement in circulation of the lymph may occur. Once every month or so the bandage can be left off for a day as a trial. If edema reappears, the support must be worn again.

A detailed description of lymphedema is given by E. V. Allen and R. K. Ghormley in the *Annals of Internal Medicine* 9:516 (Nov.) 1935.

TREATMENT OF SYPHILIS

To the Editor:—In December 1933 I began treating a white man, aged 27, for syphilis. He came to me with a rash of unknown origin on both arms. The body otherwise was normal. In 1927 he was treated for a primary lesion which healed, and for three years following the course of treatment the Wassermann reaction was negative (taken at six months intervals), at which time he was pronounced cured. The spinal Wassermann reaction also was negative. When I first saw him the Wassermann and Kahn reactions were four plus and the ensuing treatment and Wassermann reactions were as follows: January 6 and 12, 4 Gm. of neosphenamine; January 19 to March 3, seven 1 cc. doses of iodobismuth intramuscularly; March 9 to April 7, five doses of 0.4 Gm. of neosphenamine, Wassermann reaction four plus; April 18 to June 4, six doses of 2 cc. of bismuth subsalicylate in oil (0.4 Gm.) intramuscularly; June 18 to 30, 0.6 Gm. of neosphenamine (delayed reaction chill, abdominal cramps, diarrhea and temperature of 104, coming on six hours after injections); September 22 (Wassermann and Kahn reactions one plus and two plus respectively) to November 14, eight doses of 0.6 Gm. of neosphenamine; December 4 (Wassermann and Kahn reactions negative) to Jan. 16, 1935, five doses of 0.4 Gm. of bismuth subsalicylate in oil intramuscularly; June 4 (Wassermann and Kahn reactions both one plus) to July 24, six doses of 0.6 Gm. of neosphenamine; July 31 (Wassermann reaction four plus) to August 23, four doses of 0.4 Gm. of bismuth in oil; August 23 to October 17, mercury rubs three times weekly; October 17 to November 29, six doses of 0.4 Gm. of bismuth in oil; January 1936, Wassermann and Kahn reactions one plus; July 13 to August 21, six doses of 0.06 Gm. of mapharsen; September 25 to November 4, four doses of 0.06 Gm. of mapharsen and four doses of 0.4 Gm. of a bismuth compound alternating (Wassermann reaction four plus, Kahn reaction three plus); November 14 to December 2, three doses of 1 Gm. of sodium thiosulfate intravenously; Jan. 8, 1937, to February 5, four doses of 0.04 Gm. of mapharsen; February 15 to March 10, four doses of 0.4 Gm. of bismuth in oil; March 18, Wassermann and Kahn reactions 4 plus. The patient's physical examination and reflexes are normal. His weight is 124 pounds (56 Kg.). The pupils are equal and regular; they react to light and in accommodation. The spinal Wassermann test has not been done. Kindly advise me whether treatment has been inadequate and, if so, what more can I do, as I am naturally anxious to get his patient cured if at all possible.

M.D., New Jersey.

ANSWER.—The treatment given this patient following his original infection has not been described. It is presumed, however, from the statement made that he was treated only until the primary lesion disappeared. The Wassermann test as a rule will revert to negative following approximately six injections of an arsenical compound, which probably accounts for the negative Wassermann reaction between 1927 and 1930.

The patient certainly has received adequate treatment by the correspondent from 1933 until the present time. The fact that the present Wassermann reaction is still four plus may be due to several factors. One of these factors may be the inadequate treatment given during the first two or three years following infection. Other factors that may produce a persistently positive blood Wassermann reaction are syphilis of the central nervous system, cardiovascular syphilis, bone syphilis and visceral syphilis. It is suggested that a spinal puncture be done to determine the reaction of the spinal fluid at this time. It is also suggested that a thorough medical examination, including roentgenologic study in order to eliminate cardiovascular syphilis, be made. Should all these procedures prove negative, it would seem probable that this is

one of those unusual cases of Wassermann fastness with no clinical evidence of syphilis. In this case it is suggested that treatment be stopped but that the man be observed for several years, during which time frequent serologic and clinical check ups should be made.

ETIOLOGY AND TREATMENT OF ACNE OF FACE AND SHOULDERS

To the Editor:—What is the etiology of acne of the face and shoulders? A woman and her two daughters are suffering from this condition at intervals. The condition becomes more acute two days before the menstrual period and remains at the height clear through this period and two or three days following. The skin gradually returns to normal and remains so for about one week prior to the next period. These patients have been reading in the papers and magazines about wonderful results following the taking of yeast. Is this a purely allergic condition? If it is, how should I go about it to find out the cause and what is the value of yeast in these cases? Kindly advise general treatment. If place in THE JOURNAL, please omit name.

M.D., Illinois.

ANSWER.—Because of its usual advent at puberty, it has long been recognized that the development of the sex glands has much to do with the etiology of acne vulgaris. The exacerbations so often noticed at the menstrual periods as mentioned in the query emphasizes this relation. There are records of adrenal tumors in young children, accompanied by precocious sexual development and acne vulgaris.

Along with the development of hair at puberty, one can easily understand a stimulation of the sebaceous glands. Most cases of acne show abnormal activity of these glands; the skin of the face, perhaps of the back and chest, is greasier than normal. Some patients with superficial acne, however, have dry skins. It is therefore not only an increased function of the sebaceous glands that is at fault. Comedones are the forerunners of acne pustules and some cases of acne are manifested only by comedones. These are caused by an abnormality of horn formation in the outer layer of the skin. The horny layer grows at the mouth of the follicle, narrowing the orifice and preventing the semisolid sebum from being pushed out on the surface. The sebum distends the follicle just below its orifice into a bottle shape and hardens to form a solid plug. This may remain for a long time, collecting dirt on its surface, or it may soon, by acting as a foreign body, set up an irritation which results in an infiltrate of round cells, plasma cells, mast cells and giant cells. Eventually these are replaced by polymorphonuclear leukocytes and a pustule forms. This, if superficial, soon breaks, liberating the comedo and subsiding until another comedo forms. If deep, the pressure and toxins result in destruction of connective tissue and are healed by scar formation. Whether a qualitative change in the sebum has anything to do with the process is not known. Bromide and iodide internally set the process in action, as do oils or tars and tarlike substances applied externally. These may act directly on the horn-forming process in the skin or may act through changes in the sebum.

Rosenthal and Neustaetter measured the estrogen found in the blood of young girls with acne vulgaris. In only two of twenty-nine girls with normal menstruation who suffered with acne was a normal amount of estrogen found in the blood; that is, 1 mouse unit in 40 cc. of blood. In sixteen girls the amount was less than normal and in eleven there was none present. This, if substantiated by further study, will support the theory derived from clinical observation. (Rosenthal, Theodore, and Neustaetter, Theodore: Estrogenic Substance in the Blood of Patients with Acne, *Arch. Dermat. & Syph.* 32:560 [Oct.] 1935.)

Lawrence and Feigenbaum tried to treat acne in youths of both sexes by administration of the gonadotropic principle derived from pregnancy urine. They were moderately successful, as others have been. Much more experience is necessary, however, before the method can be said to be an established success. (Lawrence, C. H., and Feigenbaum, Jacob: The Treatment of Acne Vulgaris with Pregnancy Urine Extract, *New England J. Med.* 212:1213 [June 27] 1935. Lawrence, C. H.: The Anterior Pituitary-like Hormone: A Clinical Study of Its Effects in Acne Vulgaris, *THE JOURNAL*, March 21, 1936, p. 983.)

Hollander (Hollander, Lester: The Role of the Endocrine Glands in the Etiology and Treatment of Acne, *Arch. Dermat. & Syph.* 3:593 [May] 1921) thinks that cases of acne can be classified as:

1. Hyperthyroid. Thin, anemic, with thyroid hyperactivity.
2. The ruddy, overnourished type with sluggish metabolism. He asserts that the condition in type 1 improves on the administration of adrenal cortex extract, of which he gives 0.3 Gm. three times daily for two weeks and then, if indicated, the same dose four times a day for two months. Type 2 patients are given thyroid, beginning with 0.015 Gm. three times daily.

and cautiously increased. The value of the adrenal therapy has been attested by Pusey and Rattner.

Hereditry, of course, plays an important part in the etiology of acne, for the character of the skin and the peculiar combination of the endocrine glands one possesses are derived from one's ancestors.

On this prepared soil, with comedones and excessive oiliness, accompanied often by seborrhea of the scalp, secondary causes produce marked results. Anemias, cachexias and toxemias of many kinds so reduce the resistance of the skin that pus is freely formed, resulting in some cases in severe exacerbations of the disease and lifelong deformity.

Constipation has an important contributory effect. Not seldom exacerbations of the disease can be traced to this cause. Irregular hours, lack of rest, overwork and anxiety over studies may play an important part.

Local infection of the skin as a specific cause of acne has been discredited by the work of many investigators. Lack of resistance to the always present staphylococcus explains pus formation sufficiently.

Gastric hypo-acidity has been blamed for acne, probably because improvement has occurred in some cases on treatment with dilute hydrochloric acid. Immerman investigated the stomach acidity in ninety-three cases of acne vulgaris and found no satisfactory evidence of abnormal gastric secretion. (Immerman, S. L.: Gastric Acidity in Acne Vulgaris, with a Consideration of Normal Gastric Acidity, *Arch. Dermat. & Syph.* 31:343 [March] 1935.)

A pathologic sugar metabolism has also long been suspected of a rôle in the etiology of acne vulgaris. Crawford and Swartz studied ten cases of acne vulgaris; none showed abnormality of sugar metabolism and in five the condition actually improved on an increase of sugar in the diet. If further study should substantiate this report, one of the cardinal features of the dietary treatment of acne vulgaris would cease to have any scientific foundation. (Crawford, G. M., and Swartz, J. H.: Acne and the Carbohydrates, *Arch. Dermat. & Syph.* 33:1035 [June] 1936.)

White writes of acneform eruptions of the face and claims to be able, by elimination diets as suggested by Rowe and others, to establish certain foods as etiologic in certain cases. He advises the trial diet, which need not be a balanced one for the short period but in thin patients should be up to calory requirements. If no new lesions appear, foods should be added one at a time until an exacerbation occurs, showing the adverse effect of the food last added. What disease of the face he treated, whether acne vulgaris with inconspicuous comedones, acne rosacea, or one of the other less common diseases somewhat resembling acne, he does not state. (White, C. J.: Acneform Eruptions of the Face, *THE JOURNAL*, Oct. 27, 1934, p. 1277.) This theory is an interesting one but requires confirmation. Certainly acne vulgaris is not the sort of skin disease that one would suspect of sensitization. The sebaceous glands are undoubtedly quite sensitive to minute amounts of iodide or bromide, and it may easily be possible that other substances have a like effect. This is not an allergic sensitization, however.

The effect of the sodium poor, vitamin rich diet of Gerson, Herrmannsdorfer and Sauerbruch has so decided an influence on tuberculosis of the skin that it has been tried in acne. Lerner reports good results in the pustular types of acne by the use of this diet, though it must be continued for several months before the cation relations of the body can be altered. (Lerner, Charles: Nutritional Treatment of Acne Vulgaris, *Arch. Dermat. & Syph.* 31:527 [April] 1935).

The value of yeast in the treatment of acne vulgaris is supposedly due to its content of vitamin. The results as seen by dermatologists, however, have been disappointing. Few have been benefited and some have been made worse by the treatment, pustules increasing in number and size during the period of yeast therapy.

All the therapeutic results in acne vulgaris must be judged with a large portion of skepticism. The fluctuations of the disease are so unpredictable that it requires but little optimism to see improvement from many different procedures that may be mere coincidence.

The general treatment of acne consists in improving the general health in every possible way, relieving constipation if present, and regulating the hours of rest, of work and of play. The use of hot water and soap, even use of a scouring soap in the effort to loosen the tops of comedones, is advised. Ablution should be followed by the application of hot towels for ten or fifteen minutes, to be followed by a cold rub for a few minutes, drying, and application of a lotion. Sulfur lotions may be given, either solution of sulfured lime diluted with ten parts of distilled water or lotio alba (sulfured potash and zinc

sulfate, of each 2 Gm. in rose water sufficient to make 60 cc.). Either of these is dabbed on the skin and allowed to dry. (Lotio alba should be shaken before use.) When these measures make the skin dry and scaly, they should be stopped until the dryness disappears.

It is good practice to open the pustules and gently squeeze out the contents. Comedones too may be squeezed out, if the squeezing can be done without injuring the skin. If the patient does this, directions for its proper performance and a warning against the use of undue force should be given.

Vaccines and toxoids may help to cut short a pustular exacerbation. Ultraviolet exposures or sun baths to the point of slight reaction with exfoliation give temporary emptying of pustules and some comedones. It is claimed that long continuance in such treatment results in cure, but most patients get discouraged before this happy termination is reached.

Roentgen rays in small doses, from 37 to 70 roentgens once a week to each area, give the best results in the deep type of acne. They should not be given if milder measures suffice, particularly in young persons. The limit of treatment for the average case is three full skin units (900 roentgens) on each area.

Every precaution must be taken to protect against overtreatment. The patient should be warned against accepting further roentgen treatment on changing physicians, unless the doctor proposing it is aware of the dosage already received.

GLANDULAR DEFICIENCY OR DEFICIENT UTILIZATION OF CALCIUM

To the Editor:—During the past two years I have seen a number of women who have many symptoms in common and whose therapy presents a great deal of difficulty. They are all between the ages of 20 and 35. Most of them have had children but some are unmarried. Their chief complaint has usually been extreme fatigue, and this has been associated with inability to regain weight after losses that range up to 20 or 25 pounds (9-11 Kg.), nervous instability and emotionalism, sensitivity to cold and some degree of menstrual irregularity. Many of these patients have had vague gastro-intestinal symptoms and some have had diarrhea as a result of colonic instability. Mental dullness is not present in any of these cases. As a matter of fact, most of these patients have been very keen mentally. Physical examination has usually revealed underweight, dryness of the skin and hair, and a tendency in a few to acne and definite hypotension. Tachycardia has been present in a few instances. Laboratory studies have occasionally revealed a moderate, secondary type of anemia, but the most striking feature has been the low metabolic rates, which have ranged from -15 to -25. In a few instances blood cholesterols were done and were usually elevated, but not always so. The blood sugar has tended to be low. These cases have seemed to be instances of mild pituitary cachexia. In many of them, thyroid extract has been tried and has usually failed to give more than very temporary relief and frequently has failed to cause any relief of symptoms or even to elevate the metabolic rate even when given in moderately large doses. I have used Armour's anterior pituitary extract at the rate of 1 cc. three times a week without appreciable change. I have also used other anterior pituitary extracts and I have been considering the use of the adrenal cortex substance made by the Wilson Company. It has seemed to me that the general anterior pituitary deficiency, particularly of the thyrotropic hormone, was the responsible factor and that, if I could find suitable replacement therapy, the problem of treatment would be much less difficult. I will appreciate your suggestions as to treatment of these cases with specific instructions as to amounts of pituitary hormones necessary if you feel that these are indicated, and also your opinion as to which of the commercial products now available are most suitable. Please omit name.

M.D., Pennsylvania.

ANSWER.—Many of the symptoms shown by these patients, such as extreme fatigue, loss of weight, nervous instability and emotionalism, sensitiveness to cold and severe menstrual irregularity, with keen mentality, occasional tachycardia and skin disturbances, may all be due to deficient calcium utilization. In fact, they are among the classic symptoms of a disturbed calcium balance. The remaining symptoms of low blood sugar and low blood pressure are occasionally seen in the vagotonic forms of calcium deficiency.

Without knowing the complete blood chemistry or the physical examination results, such as myotatic irritability, myo-edema or a Chvostek reaction, some difficulty of course arises in making a satisfactory diagnosis.

The best suggestion is that the cases be treated as subcalcium utilization types with the administration of calcium and vitamins for the vagotonic types and calcium with parathyroid gland for the sympathicotonic ones.

Parathyroid tablets are not demonstrably effective by mouth; parathyroid extract administered three times a week hypodermically in doses of from 0.3 to 0.6 cc. as beginning doses may be employed. These injections ought not to be given oftener than three weeks a month and should be discontinued as soon as the symptoms are relieved. On no account ought they be given over long periods as routine treatment.

USE OF TETANUS TOXOID IN ALLERGIC CHILD

To the Editor:—I have a 10 year old son who is one of the most highly allergic individuals that I have ever had the misfortune to know. He had diphtheria toxin-antitoxin when an infant and is also known by skin tests to be very sensitive to horse serum. His chief allergic manifestations are severe asthma, from which he is practically never entirely free, an allergic nose, a slight amount of eczema, and formerly severe gastro-intestinal cramps. Will you be kind enough to give me the best current information on the value of tetanus toxoid? The boy is no more apt to be a candidate for tetanus and gas immunization than any 10 year old youngster, but I shudder to think of being confronted with the necessity of giving him any kind of serum. Is there a gas bacillus toxoid? Under these circumstances would you advise the use of these toxoids? What is known of the duration and strength of the resulting immunity? Your advice and reference to literature, as well as the names of companies supplying such material, will be most appreciated. Please omit name.

M.D., California.

ANSWER.—Tetanus toxoid seems to be gaining in recognition as an effective, harmless preventive of tetanus. Investigation has shown that in animals and in man tetanus antitoxin is produced in response to immunization with toxoid. In France such immunization has reduced markedly tetanus in army horses, and centers have been established for immunization of workers exposed to tetanus infection. The introduction of immunization in the army is under consideration. According to Ramon (*Rev. d'immunol.* 1:37 [Jan.] 1935) the best results are obtained by the usual three injections of toxoid followed by a further injection a month or more after the third injection or on the occasion of dangerous trauma. The immunity is believed to endure for several years. Reliable tetanus toxoid is available in this country but gas bacillus toxoid is not. At present practically nothing is known about immediate effects of tetanus toxoid or gas bacillus toxoid in children as sensitive as the boy mentioned in the question and consequently it may be safest to postpone immunizations as long as there is no grave or unusual danger of infection with tetanus or gas gangrene. Toxoids contain no serum.

LICHEN PLANUS

To the Editor:—Please outline the most widely accepted methods of treatment of lichen planus. Do sufferers from this condition have recurrences throughout life? Please omit name.

M.D., Ontario.

ANSWER.—There are many methods of treating this disease, which means that none of them are specific and sure. Any one of them may fail in any particular case. The disease occurs in two forms, the rare acute form and the ordinary chronic form.

The acute form should be soothed until its features of irritation subside. The patient should rest in bed if possible. Diet should be easily digestible and free from high flavoring, salt or smoked fish or meat, and alcohol. The urine should be examined early and at intervals. A few cases have been accompanied by glycosuria.

Soothing baths, such as the colloid alkaline bath, should be used. Three cupfuls of bran, oatmeal or starch are boiled in a gauze bag to make a porridge. A cupful of baking soda is stirred into a half tubful of water, the gauze bag of porridge is stirred and squeezed in the bath, and the temperature of the latter brought up to 37 C. before the patient gets in. If the water does not cover the patient completely, towels, kept wet and warm, should supplement it. The first bath should be of only ten or fifteen minutes' duration, but later ones may be longer if well received.

Instead of this, Jacquet's "douches sédatives" may be used, a spray under moderate pressure at a temperature of about 35 C. for from two to five minutes, then a short cold rinse. Alkaline diuretics are sometimes of value, given well diluted after meals.

Some authorities report striking improvement after lumbar or cisternal puncture and the withdrawal of from 10 to 15 cc. of fluid. Sun baths or mild ultraviolet rays have been helpful to some, always less than an erythema dose.

Roentgen rays given over the spine have been used by many dermatologists. One method of such treatment consists in drawing four areas 6 by 2 inches each side of the spine of the prone patient, leaving an untreated strip an inch wide along the spine. Hard rays, 180 kilovolts, are given at a distance of 50 cm. in a slanting direction through these areas so as to cross at about the depth of the spinal cord. A one-fourth inch copper filter is used and one-half erythema dose given to each field once in three weeks for three such exposures. (Andrews, G. C.: *Diseases of the Skin*, Philadelphia, W. B. Saunders Company, 1930, p. 465).

Ointments containing 1 per cent phenol and from 0.25 to 3 per cent menthol may be used for the itching. If widely used, the urine should be frequently examined to guard against

phenol poisoning. Too extensive application of the menthol preparation should not be made for fear of chilling, particularly in sensitive or old patients. Menthol preparations should not be used near the eyes.

After subsidence of the acute symptoms, infectious foci should be cleared up, if possible.

For chronic cases, the general and local remedies already mentioned are often of value. Arsenic as solution of potassium arsenite, asiatic pills by mouth, sodium cacodylate subcutaneously, or mercury salicylarsenate either intramuscularly or intravenously, may be used. Arsenic is the chief remedy and often has to be used in large doses for a long time.

Bismuth compounds, given intramuscularly as for syphilis, has proved valuable in many cases. Yellow mercurous iodide or mercury with chalk by mouth, or the soluble or insoluble salts intramuscularly, is often of great value. The urine must be examined at regular intervals during the administration of any of these metals, and their use stopped on the appearance of albumin or casts.

The arsphenamines have not been of great value in the treatment of lichen planus.

High frequency currents or galvanic electricity, from 4 to 10 milliamperes, given frequently to the patches, are credited with clearing the eruption. Darier recommends high frequency or static baths. (Darier, J.: *Text Book of Dermatology*, translated and edited by S. Pollitzer, Philadelphia, Lea & Febiger, 1920, p. 136.)

Foreign protein therapy, injection of milk and vaccines are sometimes helpful. Stronger ointments of phenol, mercurials, tar and chrysarobin are used for local application to patches of lichen planus. It is well, as Pusey suggests, to begin with the milder strengths and increase them as needed. (Pusey, W. A.: *Diseases of the Skin*, New York, D. Appleton & Co., 1924, p. 456.)

The hyperkeratotic papules of hypertrophic lichen planus must first be softened by applications of sodium or potassium hydroxide or by salicylic plaster or salicylic collodion before treatment can be applied successfully.

	Gm. or Cc.
1. Phenol	0.3
Ammoniated mercury ointment.....	30.0
2. Crude coal tar.....	ad
Zinc oxide	2.0
Petrolatum	30.0
(This may be made stronger as needed, or the undiluted crude coal painted on.)	
3. Chrysarobin	ad
Salicylic acid	1.0
Petrolatum	30.0

The chief rules of treatment are:

1. Soothe the acute cases.
2. Stimulate the chronic cases.
3. Persist.
4. Watch for signs of intolerance.

Recurrences of lichen planus are reported after long periods of freedom from the disease. More often, a few lesions remain for a long time and then there is a relapse. The disease persists for many years, one case of twenty years' duration being known. These, however, are exceptions to the rule that lichen planus clears under weeks or months of persistent treatment and does not recur.

INDICATIONS FOR FEVER THERAPY IN DEMENTIA PARALYTICA

To the Editor:—Is fever therapy contraindicated in the following case? A man, aged 33, since March 1936 has had a right hemiplegia with spasticity of the right upper and lower extremities. There is a mild impairment of memory for recent events as the only evidence of any mental involvement. The blood Wassermann and Kahn reactions are 4 plus; the spinal fluid Wassermann reaction is 4 plus in 1, 0.5 and 0.2 cc.; Ross Jones 1 plus, Pandey 2 plus. There are 9 cells and the colloidal gold curve gives a reading of 5555544320. Please omit name.

M.D., Illinois.

ANSWER.—If the laboratory reports of the spinal fluid examination are correct, it is evident that the patient is suffering from dementia paralytica. It is not certain, however, why the patient developed a right-sided hemiplegia. Not enough clinical data are available to allow one to judge whether this was due to a hemorrhage, to a thrombosis of the cerebral vessels or to some other factor. If the patient is to be treated with pyretic therapy it would be important to know whether his blood pressure is exceedingly high and whether the blood vessels in his brain are friable. If the case is one of thrombosis of some of the cerebral vessels, which occurred in March 1936, fever therapy would be advisable. If it is a cerebral hemorrhage due to hypertension and a syphilitic involvement of the cerebral blood vessels, fever would be contraindicated. All forms of

pyretotherapy have a tendency to increase the systolic and lower the diastolic blood pressure, thus increasing the pulse pressure. For this reason fever, even when produced by physical agents, has a tendency to put a greater load than usual on the entire cardiovascular system.

TREATMENT OF POMPHOLYX

To the Editor:—Would you please advise me as to the latest treatment of pompholyx.

R. W. BENZ, M.D., Honolulu, Hawaii.

ANSWER.—In order to approach the problem of therapy in pompholyx properly the various etiologic factors that might produce this condition must be given consideration. The conception of pompholyx and the dyshidrosiform dermatoses has been the subject of much discussion, and the grouping suggested by Wise and Wolf (*Arch. Dermat. & Syph.* 34:1 [July] 1936) gives a broad conception of the possible etiologic factors that must be given consideration in treatment. They include:

1. Eruptions due to superficial mycotic infections—infections with *Trichophyton*, *Epidermophyton* and yeasts.
2. Eruptions of secondary nature resulting from primary fungous foci—epidermophytids, moniliids and trichophytids.
3. Eruptions caused by exogenous irritants. These fall in the category of dermatitis venenata, occupational dermatoses, trade eczemas, industrial dermatoses, dermatitis eczematosa and so forth. These eruptions are encountered most frequently among dyers, furriers, painters, tanners, leather-workers, barbers, hair-dressers, photographers, workers in ammunition and rubber factories, and in the electrical and oil industries, printers, typesetters, persons who handle food, florists, chemists, druggists, surgeons, dentists, nurses and persons in scores of other occupations and professions.
4. Vesicular eruptions of unknown cause—"eczema," dermatitis eczematosa and pompholyx.
5. Toxic eruptions caused by drugs, foods, etc.

The eruptions representing these groups are at times clinically indistinguishable from one another, and it is essential in the suggested therapy of pompholyx to rule out any of the known etiologic factors.

Pompholyx, per se, is included with the "vesicular eruptions of unknown cause." The local treatment of pompholyx consists of wet compresses of solution of aluminum subacetate, diluted with from 10 to 16 parts of water, or wet compresses of calamine lotion with phenol if itching is severe. Vesicles or bullae are punctured and drained. Fractional x-ray exposures, from 75 to 88 roentgens weekly, to the affected sites are of value. In the dry, scaling stage, the use of 3 per cent ichthammol ointment or 3 per cent salicylic acid and 3 per cent sulfur precipitate in petrolatum is of value. General tonic treatment with the use of arsenic and hematinics is sometimes indicated.

The removal of any etiologic factors mentioned in the outline, and their special treatment, are essential for success in therapy.

PERIODIC INTERMENSTRUAL PAIN

To the Editor:—I should like some information for the treatment of a woman, aged 39, who for a number of years has had periodic pain occurring in the midpelvic region. A number of years ago she had her appendix removed for a similar type of pain. During the past year I have been able to associate this pain definitely with ovulation, as it invariably occurs from thirteen to fourteen days before menstruation, which is irregular, and lasts from an hour to two to several days, and at no time has there been a recurrence until the next midmenstrual period. What can be done in the way of treatment? At times the pain has been severe enough to require morphine. Would an artificial menopause by the use of high voltage x-rays be indicated?

J. R. JARVIS, M.D., Ohio.

ANSWER.—The case is apparently a typical instance of periodic intermenstrual pain, or "mittelschmerz," which has long been looked on as related in some way to ovulation, though the exact mechanism is still unknown. The pain may be of mild degree but in some cases is so intense that it has led to the mistaken diagnosis of some acute abdominal disease, such as acute appendicitis or tubal pregnancy.

In the milder forms of ovulation pain no treatment may be necessary or, at most, some simple analgesic, such as codeine or some other suitable product, together with rest and the local use of heat. For the more severe forms, surgical intervention has often been resorted to, either designedly or under the mistaken diagnosis of some other pelvic condition. Removal of the ovary on the affected side has apparently been the most frequently successful procedure, though the pain may at times recur on the opposite side. In the case described by the correspondent the patient is nearing the menopausal age, and, if the symptoms are sufficiently severe, if they are not relievable by simple measures, and if the question of further reproductive-ness is not of importance in this patient, the x-ray induction

of the artificial menopause would be justified and should relieve the condition. For a recent article on this general subject the correspondent may be referred to the paper of Wharton and Henriksen, published in *THE JOURNAL*, Oct. 31, 1936.

TOXICITY OF SPRAY PAINTING

To the Editor:—In the past month I have had two employees of the furniture company who operate spray varnish machines and who blame the occupation for their complaints. They work under a hood with an exhaust fan but state that it is inefficient and that the varnish has a naphtha base, which is the ingredient that they claim caused the difficulty. The first one had symptoms simulating peptic ulcer and stated that if he stayed away from the vapor he was all right. He refused to have x-ray and gastric analysis done. There was no diarrhea, and physical examination revealed nothing. The second man had a sore throat, which was the ordinary follicular tonsillitis, and I am positive that the fumes had nothing to do with the infection. It cleared without difficulty or sequelae. I have looked through my available literature without finding anything that would lead me to believe that the occupation has anything to do with either case; but I can easily believe that the constant inhalation of such fumes might lead to gastro-intestinal difficulties. Am I correct and what are the symptoms and signs of such intoxication and what systems are most affected? Where might I find additional references to such industrial hazards? Please omit name.

M.D., Pennsylvania.

ANSWER.—All organic solvents are more or less toxic and somewhat anesthetic. Those which have a naphtha base may be less harmful than some of the others, but it is rash to generalize on the subject. Men doing such spraying should be equipped preferably with masks supplied with fresh air under slight pressure. A list of firms supplying such equipment can be had from the United States Bureau of Mines, Pittsburgh.

The toxicology of most of the organic solvents commonly used in paints and varnishes is given under their chemical names in Flury, Ferdinand, and Zangger, Heinrich: *Lehrbuch der Toxicologie für Studium und Praxis*, Berlin, Julius Springer, 1928. See also "Poisoning by Petroleum Distillates" by E. R. Hayhurst, which appeared in *Industrial Medicine*, vol. 5, February 1936.

BRONCHIAL ASTHMA

To the Editor:—In the past two months I have had an unusually large number of patients with bronchial asthma. They have eosinophilia. They have negative skin tests with ragweed. Their attacks occur between September and the end of November. Am I justified in giving these patients a series of ragweed pollen injections? Is it usual that asthma cases do not show the offending agent by the skin test? Please omit name.

M.D., New York.

ANSWER.—This inquiry does not give sufficient data for more than a general answer. No mention is made of symptoms of hay fever preceding the attacks of asthma from September to November. Patients with asthma due to ragweed pollen give a typical history of symptoms of hay fever coming on in mid-August (in the region noted). The attack of asthma usually starts near the end of August and in cases of long standing may persist for a month to several months after the end of pollination. The attacks of asthma may not be preceded by hay fever in some cases of long standing. Occasionally also a patient may develop pollen asthma with no previous history of ever having had hay fever. Skin reactions are present in such a large proportion of pollen sensitive patients that their absence in known pollen sensitive patients has been considered worth recording:

Kern, R. A.: Seasonal (Pollen) Hay Fever with Negative Skin Tests, *Ann. Clin. Med.* 5: 371, 1926.

Kahn, I. S.: Significance of Negative Skin Tests in Pollen Hay Fever and Asthma in Infants and Young Children, *South. M. J.* 21: 559 (July) 1928.

Wilmer, H. B.: Diagnosis and Treatment of the Atypical Types of Hay Fever, *J. Allergy* 1: 87 (Nov.) 1929.

In the presence of a history of seasonal asthma suggestive of pollinosis, the scratch test, if negative, should be followed by intradermal tests with the suspected pollen, a 1:10,000, a 1:1,000 and, if necessary, a 1:100 pollen solution being used for such tests. If these tests are still negative, a conjunctival test (placing the pollen grains on the inside of the lower eyelid) or an intranasal test by insufflation of pollen should be done. If such study still produces negative results, other tests, especially for molds (with special reference to *Alternaria* and *Aspergillus*), should be done. Mold-sensitive patients give a history very similar to the history of those who are pollen sensitive. If all these studies have failed to explain the patients' symptoms, one may then, in patients giving a characteristic history, try the use of ragweeds. As previously mentioned, the percentage of such cases is small.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, May 29, page 1912.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*, June 21-23 and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral examinations for Group A and B applicants* will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Practical examination* will be given at Philadelphia in June. *Written examination* will be held in different centers of the United States and Canada in October. Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7 and Chicago, Oct. 9. *All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Atlantic City, N. J., June 8. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Philadelphia, June 7-8. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Mich.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF SURGERY: *Part I (written)*, Sept. 20. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Oral examination*, Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

West Virginia March Report

Dr. Arthur E. McClue, secretary, West Virginia Public Health Council, reports the oral and written examination held at Charleston, March 1-3, 1937. The examination covered 11 subjects and included 110 questions. An average of 80 per cent was required to pass. Fifteen candidates were examined, all of whom passed. Twelve physicians were licensed by reciprocity and 3 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1935)		89.5
Northwestern University Medical School.....	(1937)		88.8
Rush Medical College.....	(1936)	87.6, 89, 90.2,	90.6
School of Medicine of the Division of the Biological Sciences.....	(1931)		89.7
Louisiana State University Medical Center.....	(1936)		90.2
University of Michigan Medical School.....	(1934)		85.1
Cornell University Medical College.....	(1933)		84
Duke University School of Medicine.....	(1932)		87.2,
(1935) 84.9, 88.8			
University of Cincinnati College of Medicine.....	(1935)		88.9*
Western Reserve University School of Medicine.....	(1935)		91

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Georgia Medical Department.....	(1928)		Georgia
Rush Medical College.....	(1936)		Michigan
University of Louisville School of Medicine.....	(1927), (1933)		Kentucky
Louisiana State University Medical Center.....	(1934)		Louisiana
University of Michigan Medical School.....	(1935)		Penna.
Duke University School of Medicine.....	(1932, 2)		N. Carolina
Western Reserve University School of Medicine.....	(1933)		Ohio
Meharry Medical College.....	(1931)		Tennessee
Medical College of Virginia.....	(1931), (1933)		Virginia

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Rush Medical College.....	(1930)	N. B. M. Ex.	
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1933)	N. B. M. Ex.	
Woman's Medical College of Pennsylvania.....	(1931)	N. B. M. Ex.	

* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

Kentucky Reciprocity Report

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports 15 physicians licensed by reciprocity from Jan. 6 through April 4, 1937. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine.....	(1934)		Mississippi
Northwestern University Medical School.....	(1936)		Illinois
University of Louisville School of Medicine.....	(1934)		New Jersey
University of Minnesota Medical School.....	(1933)		Minnesota
Ensworth Medical College, Missouri.....	(1912)		Nebraska

Washington University School of Medicine.....	(1933)		Missouri
Eclectic Medical College, Cincinnati.....	(1914), (1936)		Ohio
Temple University School of Medicine.....	(1932)		Penn.
Tennessee Medical College.....	(1905)		Tennessee
University of Tennessee College of Medicine.....	(1934)		Tennessee
Vanderbilt University School of Medicine.....	(1929)		Tennessee
(1934) Tennessee			
Medical College of Virginia.....	(1934)		Virginia
University of Virginia Department of Medicine.....	(1933)		Virginia

Montana April Report

Dr. S. A. Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held in Helena, April 6-7, 1937. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Four candidates were examined, 3 of whom passed and one failed. Six physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1930)		88.1
Vanderbilt University School of Medicine.....	(1933)		79.8
University of Alberta Faculty of Medicine.....	(1936)		81.9

School	FAILED	Year Grad.	Per Cent
University of Edinburgh Faculty of Medicine.....	(1926)		57.1

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1934)		Wyoming
(1936) Oklahoma			
University of Minnesota Medical School.....	(1927)		Minnesota
Creighton University School of Medicine.....	(1921), (1932)		Nebraska
University of Pennsylvania School of Medicine.....	(1927)		N. Carolina

Maine March Examination

Dr. Adam P. Leighton, secretary, State of Maine Board of Registration of Medicine, reports the written examination held in Portland, March 9-10, 1937. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventeen candidates were examined, all of whom passed. Two physicians were licensed by reciprocity and 2 physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George.....	(1935)		80
Rush.....	(1936)		81
Boston.....	(1936)		85
Harvar.....	(1936)		84

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Boston University School of Medicine.....	(1934)	N. B. M. Ex.	
University of Rochester School of Medicine.....	(1934)	N. B. M. Ex.	

Book Notices

A Textbook of Medicine. By Charles Phillips Emerson, M.D., Research Professor of Medicine, Indiana University. Cloth. Price, \$8. Pp. 1,296. Philadelphia, London & Montreal: J. B. Lippincott Company, 1936.

The purposes of this new textbook are outlined in the preface by the author. The aim is to present internal medicine in terms of the clinical pictures of diseases, explaining these by the fundamental facts of pathology, biochemistry and other fields. The symptoms, therefore, are related so far as possible to disturbances of fundamental nature. The author believes that the history of some diseases is important in understanding them as well as being matters of interest, and hence he includes several short biographies of men important to medical progress. Each disease syndrome is presented as a defense mechanism. It is either the result of a struggle between the patient's body and invading germs or the expression of an attempt of the various organs to function efficiently in spite of lesions or dysfunctions. This task is quite unenviable. Nevertheless the degree of success obtained is noteworthy. Naturally it was impossible to discuss any of the diseases or disorders completely. The relative space assigned to each subject, however, is exceptionally well chosen. Classification of the diseases naturally is difficult and in this instance has resulted in some faults of arrangement which should be remedied in subsequent editions. Thus food infections are considered under both specific infectious diseases and diseases due to drugs and poisons. Lobar pneumonia is placed under specific infectious diseases, while acute pleurisy is placed with diseases of the organs of respiration. Omissions are remarkably few. Little controversial material is found, although some workers in the field would differ with the author's statement in his section on gout that "the determination of the uric acid of the blood and urine aids but little in this diagnosis, since both may lie within normal limits." One may safely say that this textbook is as satisfactory as it is possible for any one man to achieve today. The index is exceptionally good and evidently has received a great deal of attention, as can be judged by its eighty-five page length.

An Introduction to Comparative Biochemistry. By Ernest Baldwin, B.A., Ph.D., University Demonstrator in Biochemistry, Cambridge. With a foreword by Sir Frederick Gowland Hopkins, F.R.S. Cloth. Price, \$1.50. Pp. 112, with 11 illustrations. New York: Macmillan Company; Cambridge: University Press, 1937.

Baldwin has written the first textbook on the evolution of animals from a chemical point of view. It is a lucid work. Perhaps the part of most interest to physiologists and physicians is that on water balance and kidney action. By tracing the entire evolution of the kidneys, the subject is a great deal more intelligible than it would be if taken up merely from the standpoint of the mammalian kidney. The simplest kidney action is merely the pumping out from the body of water containing waste products, and this water is then replaced by osmosis. The first difficulty arises in adaptation to fresh water in which there is not enough salt in the incoming water, and work has to be performed by the kidney in pumping out a hypotonic urine. After the filtrate of the blood passes out of the glomerulus or a similar organ, a salt-absorbing segment is added. The adaptation to a dry condition has led to the abolition of the glomerulus in marine bony fish, snakes and lizards and to the development of the loop of Henle in birds and mammals. The passage of embryonic and larval stages inside an egg shell or uterus is an adaptation to fresh water and land conditions for the preservation of the salts. Protein metabolism is affected by a scarcity of water, aquatic animals starting out with ammonia as a form of excretory nitrogen, requiring a great deal of water for its dilution to diminish its toxicity. The development of urea is to detoxify ammonia, but this also requires some water for its excretion. Uric acid can be excreted in the solid form and thus conserve water. Baldwin accepts the arginase theory of urea formation and concludes that uric acid arises only from other purines and not from urea. On the other hand, uric acid may be broken down into urea through the intermediate stage of allantoin. He states that smooth, striated and heart muscle of all animals contains phos-

phagen, although this is phosphocreatine in the higher animals and phospho-arginine in the lower animals. Hemoglobin and other respiratory pigments are considered adaptations to lack of oxygen, the wide distribution of hemoglobin being due to its having the same prosthetic group as cytochrome, which is universally present. Hemocyanin, on account of having a lower loading tension for oxygen, is advantageous to animals in passing from water to a land habitat; but, once that habitat is established, hemoglobin is the more efficient. He notices that the blood pigment is kept in the blood vessels by high molecular weight or confinement in the corpuscles, that dissolved in the plasma having molecular weights of about 2,000,000. He considers cytochrome and the yellow respiratory enzyme of Warburg, the latter not requiring a cyanide sensitive oxidase for its action. He mentions the fact that methylene blue as a carrier of oxygen increases the rate of respiration. So does the natural bacterial pigment pyocyanin, and also hallachrome and echinochrome. The theory of Raper of melanin formation is accepted and hallachrome, a red pigment of worms, is considered an intermediate. The book seems remarkably free from errors, the only one noted being that the salt content of the Great Salt Lake is given as 10,000 times too small. Perhaps the best section of the book is the foreword by Sir F. Gowland Hopkins, in which he says "I venture to think that productive thought in biochemistry in particular calls for the widest possible survey of life's manifestations." Some of the pioneers in medicine have been leaders in botanic investigations also, and even today a wide range of interest is conducive to contributions to knowledge.

Festschrift zum 80. Geburtstag von Hofrat Prof. Dr. Hans Molisch. [Sonderband zu Mikrochemie Band XXI.] Paper. Price, 28 marks. Pp. 454, with 82 illustrations. Vienna & Leipzig: Emil Halm & Co., 1936.

As a special mark of esteem on his eightieth birthday, friends and pupils of Professor Molisch joined in honoring the Nestor of applied microchemistry by dedicating to him the results of some of their work, which was inspired by his teaching. Emil Halm, the publisher, founder and ever ready financial sponsor of *Microchemie*, and the editors, A. A. Benedetti-Pichler, Emich, Friedrich, the late Pregl, Lieb, Lindner, Koffer and Niederl, are to be thanked for their effort in issuing anniversary volumes at intervals in honor of the distinguished pioneers of microchemistry. Microchemistry is Austria's distinct contribution to chemistry. Without it, modern research in biologic chemistry and experimental medicine could not have progressed so rapidly. The journal *Microchemie* is indispensable to every biochemical worker, as it contains the minute details of procedures in microchemical investigations. It is impossible in this brief review to give due credit individually to each scholarly contribution in the Molisch festschrift. However, the article by A. A. Benedetti-Pichler and W. F. Spikes on "Studies in Qualitative Separations on a Micro-Scale" deserves special emphasis, as the authors describe a procedure long needed for basic qualitative micro-analysis. It is hoped that in the future America may make its contribution, perhaps, by erecting a microchemistry institute that may serve as a center for Americans who are unable to study abroad. Possibly some of the pupils of these illustrious teachers—Emich, Donau, Lieb, Pregl and Feigl—might carry on their work here. May Professor Molisch live to see this day and, together with Emich, dedicate such an institution for the benefit of humanity.

The Pharmaceutical Recipe Book (R. B. 11). By Authority of the American Pharmaceutical Association. Prepared by the Committees on Recipe Book and on Unofficial Formulas of the American Pharmaceutical Association. Second edition. Cloth. Pp. 529. Washington, D. C.: American Pharmaceutical Association, 1936.

As stated in the preface, the Recipe Book represents the outcome of an effort of the American Pharmaceutical Association to place in the hands of the practicing pharmacist a reliable and comprehensive book of recipes applicable to his business. The volume is divided into several parts relative to different types of formulas: part 1, pharmaceutical; 2, flavoring extracts; 3, dental; 4, chiropodologic; 5, veterinary; 6, photographic; 7, cosmetic; 8, technical and miscellaneous; 9, laboratory reagents; 10, schedule of antidotes for poisons; 11, average doses of

unofficial drugs, and 12, table of solubilities. The type and typography of the book resemble the U. S. Pharmacopeia XI and the National Formulary VI, somewhat tending to lend an official air. There are nearly 2,000 formulas covering the unofficial ones commonly used in the drug store, the hospital and the laboratory; also many that are frequently used about the boudoir, the household and the workshop. As far as the value of the volume to the physician is concerned, it is more serviceable in indicating relics of the past than present day progress. The book is an advancement over the usual formulary describing polypharmaceutic mixtures or imitations—"patent medicines"—heretofore exploited by certain publishers. The volume is to be commended, however, in that it does not advance any claims for remedial action or assume any responsibility for the therapeutic values of any of the formulas or specify dosage.

Applied Physiology. By Samson Wright, M.D., F.R.C.P., John Astor Professor of Physiology, University of London, Middlesex Hospital Medical School. Sixth edition. Cloth. Price, \$6. Pp. 686, with 282 illustrations. New York & London: Oxford University Press, 1936.

A record of six editions in ten years would seem to indicate that this book has found a most useful place in its field. The present edition provides new considerations, particularly in relationship to cerebral localization, reflexes, speech, metabolism and the glands. The author expresses his special appreciation to the series on glandular physiology and therapy published in *THE JOURNAL*. He has, moreover, added extensively to the methods and technics that are described in the work as these have been brought out in current periodical literature. Attention is called to nineteen new illustrations and to the redrawing of many of the older illustrations in order to make them more illustrative. The author has also borrowed freely from well established textbooks in related fields to improve the quality of his excellent work. In his table of contents he indicates in italic those sections of the work which are particularly of clinical interest, thus enabling the practitioner who wishes to bring himself down to date to read readily those portions of the work which concern him. More and more the practice of internal medicine and of surgery is coming to ground itself in physiology. The title of this book indicates its practical service as a liaison volume between the basic sciences and the practice of medicine. Its numerous prompt revisions indicate its timeliness and its dependability.

Clinical Laboratory Diagnosis. By Samuel A. Levinson, M.S., M.D., Director of Laboratories, Research and Educational Hospitals, Chicago, and Robert P. MacFate, Ch.E., M.S., Assistant Director of Laboratories, Research and Educational Hospitals, Chicago. Cloth. Price, \$9.50. Pp. 877, with 157 illustrations. Philadelphia: Lea & Febiger, 1937.

As time moves on, the teachers of a previous period and the textbooks which represented their technics of pedagogy are replaced by a new generation and a new series of volumes. It is occasionally possible for a modern reviser to build on the foundations of the past. Levinson and MacFate have, however, chosen to present an entirely new work based on the outlines which they distribute to their own students at the University of Illinois College of Medicine. They have thought it wise to include enough data in the fundamental fields of anatomy, physiology, biochemistry and clinical medicine to provide the student with a rational approach to laboratory technic. In most instances they supply the approved technic without attempting to list all of the various methods that are available. For their hematology they are indebted largely to Dr. Jaffé of the Cook County Hospital, and for their pediatric procedures to Dr. H. G. Poncher. Likewise their section on legal medicine and toxicology is an outgrowth of the work carried on by the coroner's toxicologist, Muehlberger. The volume is systematically arranged, considering first the tests involved in the gastrointestinal tract from the mouth to the rectum. It follows with metabolism, blood and urine, hematology, immunology, spinal fluid bacteriology, skin tests and then the special topics that have been mentioned. The book is beautifully printed, its outlined character fully apparent by the nature of the headings that are used on individual chapters, paragraphs and similar subdivisions. The illustrations are profuse and chosen obviously with a desire to be of the greatest possible helpfulness. There

are a considerable number of plates, some of them in color. An efficient index forty pages in length concludes the work. It may be unqualifiedly recommended to physicians and students as a succinct, authoritative and useful laboratory guide.

Om Amylasen i Blod og Urin: Dens Udskillelse gennem Nyrerne. Af Gregers Nørby. Paper. Pp. 148, with 29 illustrations. Copenhagen: Levin & Munksgaard, 1935.

The author gives a discussion of the methods for determination of amylase, their application to blood and urine and the errors involved. In determining the amylase of the blood, the author found that it was all contained in the plasma, none being present in the corpuscles. Although the amylase of the plasma was rather constant from day to day in the individual case, rather wide differences were found between different individuals. The stability of amylase in the urine was studied and it was found that at temperatures under 40 C. and at a pH from 5.0 to 9.0 the specimens retained their amylase content rather well. The excretion of amylase in the urine was found to be proportional to the concentration in the serum. The author also studied the excretion of creatinine, using a Pulfrich "stufenfotometer" for its determination. The excretion per unit of time was found to be a linear function of the concentration of creatinine in the serum. The excretion of amylase and of creatinine seemed to be independent of each other. Because of the exhaustive discussion of methods for the determination of amylase and of creatinine, this monograph should prove of value to all interested in the subject.

Relief and Health Problems of a Selected Group of Non-Family Men. By Glenn H. Johnson, Research Assistant, School of Social Service Administration, University of Chicago. University of Chicago Social Service Monographs. Paper. Price, 50 cents. Pp. 81, with illustrations. Chicago: University of Chicago Press, 1937.

One hundred and forty-four men whose only identifying factor common to all is that they are not living with families of their own are studied. Half of them had lived in Cook County for twenty-six years or more, while only eight had less than ten years' residence. Only twenty of these men had been known to any case work agency, so that they were in general a self-supporting group until economic conditions or some temporary or chronic illness brought them to a relief office. The conditions of housing were extremely poor, only sixty-three having sleeping quarters that could be characterized as good. Yet there was a tendency to cling tenaciously to a freedom of choice of those things which are personal and intimate. Only fourteen were without some physical or mental health complaint. Special housing provisions and convalescent homes are needed for the care of this class. Although a majority were poorly educated, there were ten high school and four college graduates; seventy-five were rated as employable. The report recommends the abolition of "shelters" and characterizes the "family responsibility" requirements of the Illinois Pauper Law as a retrogressive public policy. Invalidity pensions are also recommended. Existing relief programs are declared to be inadequate to meet the needs of this class.

Einführung in die pathologische Physiologie. Von Professor Dr. Max Bürger, Direktor der medizinischen Universitäts-Poliklinik, Bonn a. Rh. Second edition of "Die pathologisch-physiologische Propädeutik." Paper. Price, 24 marks. Pp. 454, with 43 illustrations. Berlin: Julius Springer, 1936.

This distinctive and carefully written book covers the general field of abnormal or applied physiology and is therefore of special interest to third and fourth year medical students. In addition, however, it should interest all those who are endeavoring to improve the practice of medicine in the matter of accurate diagnosis and rational treatment. It is written by a clinician who for years has lectured to students on this subject and who draws on an extraordinary repertory of physiologic and biochemical information. In his introduction Bürger points out the fallacies of the old "organ diagnosis" in internal medicine and emphasizes the interdependence of the various parts of the body. While this idea is gaining ground in medicine, its implications still require emphasis, and the book abounds in excellent illustrations of it (e. g., psoriasis, p. 320). More discrimination is needed in the ordering of such things as "strict bed rest" and "hot dressings." This book deserves careful reading and a translation into English.

The Social Workers' Dictionary. General Editors: Erle Fiske Young, Ph.D., and Bessie Avene McClenahan, Ph.D., The School of Social Work, The University of Southern California. Editor for Social-Legal Terms: Pauline V. Young, Ph.D., The School of Government, The University of Southern California. Paper. Price, 75 cents. Pp. 71. Los Angeles: Social Work Technique, 1936.

This pamphlet indicates the manner in which the field of social service has gradually developed not only a new profession but also a new language for that profession. The social service worker must obviously be acquainted not only with the language of medicine and of the hospital but also with the terms used by patients in discussing their illnesses, their manner of living and their ability to pay. The authors of this book have carefully compiled most of the difficult terms that are likely to arise in such discussions and their definitions are exceedingly apt. The book is hardly one that will be useful for the physician but no doubt the rapid growth of social service, including the incorporation into the midst of this profession of some 200,000 amateurs, indicates the need for such a book.

Lysozyme. Typhoid Fever. Diphtheria. Rheumatism. Ukrainian Metchnikoff Institute, Symposium of the Institute's Works. Paper. Price, \$1. Pp. 322, with illustrations. Kharkov: The Institute, 1936.

This book deals with the results of investigations at the Metchnikoff Institute of Kharkov under the direction of M. Melnik. There are four main topics: lysozyme, the stable substance discovered by Fleming in 1922 in various products and tissues of the animal body, which in neutral or slightly alkaline medium dissolves various bacteria, saprophytic as well as pathogenic; single immunization against typhoid by injecting vaccine and culture filtrate of typhoid bacilli with alum, thus producing an antigenic depot; single immunization against diphtheria with alum precipitated toxoid; streptococcic allergy and rheumatism. The parts dealing with lysozyme and anti-diphtheria immunization are in English, the two other parts in French. The book is well printed on substantial paper. Its contents will interest those who are concerned with the topics discussed.

Wide Is the Gate. By Loyd Thompson. Cloth. Price, \$2. Pp. 320. New York: Macaulay Company, 1937.

Here in a fictional form is an accumulation of information concerning the methods of charlatanism, particularly as practiced in the United States, from the least of these to John R. Brinkley. Informed readers will recognize in many of the descriptions the actual record of Brinkley himself. While the author lacks the sure fictional touch of the experienced story writer, his volume includes sufficient drama to sustain the factual data that are incorporated in the story. It may be doubtful that the general reader will find the book as fascinating as will the medical reader, but either will derive from it much that is informative and at least a considerable amount of material that is interesting.

Vocational Guidance Throughout the World: A Comparative Survey. By Franklin J. Keller, Principal, Metropolitan Vocational High School, New York City, and Morris S. Vitels, Associate Professor of Psychology, University of Pennsylvania. Cloth. Price, \$4. Pp. 575, with illustrations. New York: W. W. Norton & Company, Inc., 1937.

Vocational guidance has become in recent years a subject of general as well as professional study. The book under consideration, which is principally a comparative survey of vocational guidance throughout the world, can be read with profit by those lacking in technical training in the field as well as by those professionally concerned. Vocational guidance in other countries is discussed against the background of existing conditions in the United States. Each country is introduced with a brief description of that social, political and economic background which is essential in understanding the formulation of vocational guidance policies and methods. These introductions are moderate in tone and sympathetic in point of view. It is refreshing to find that this holds true for fascist, communist and democratic countries alike. Much is thus added to the understanding of the ensuing material. Two chapters, on psychologic methods in vocational guidance and psychologic methods for the analysis of the individual, are placed in the middle of the book between the discussion of Switzerland and that of Italy. The reason for inserting these chapters in this

portion of the book seems somewhat obscure. An appendix containing samples of general record forms, questionnaires, certain psychologic tests, medical contraindications and miscellaneous material is included. The book is so written that it will serve to interest the layman with only a casual knowledge of the field as well as those more professionally involved, for whom it would seem to be indispensable.

Meditsinskaya literatura USSR: Sistematicheskiy ukazatel knig i zhurnalnykh statey 1933. God izdaniya tretiy. [Medical Literature of Russia: Systematic Index of Books and Articles for 1933. Third Year of Issue.] Cloth. Price, 20 rubles, 6 kopecks. Pp. 294. Moscow & Leningrad: Gosudarstvennoe izdatelstvo biologicheskoy i meditsinskoy literatury, 1936.

The present volume is an index of biologic and medical literature published in the Soviet Union for the year 1933. The Bureau of the All-Union Institute of Experimental Medicine for publishing medical bibliography has decided to utilize bibliographic material collected by Dr. A. E. Molotkov and covering the Russian medical literature from the sixteenth century to 1929. The plan is much like that of the *Index Medicus*, with its general subdivisions, an index of the authors and subject index, with the difference, however, that a brief subject content is appended to each reference. The text is in Russian only, making the material largely inaccessible except to those familiar with the language.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Fracture of Hip; Migration of Bone Peg Into Bladder.—In October 1933 the plaintiff sustained an intracapsular fracture of her left femur, and the defendant, an orthopedic surgeon, performed an operation to reduce the fracture, inserting a bone peg about 5 inches long and approximately five-sixteenths of an inch in circumference to hold the fragments in apposition. An infection later developed in the hip, and drainage was instituted. Shortly thereafter, the plaintiff's abdomen became distended and she suffered intense pain. The distention disappeared under the family physician's treatment in a few weeks. At various times during the next three or four months the plaintiff experienced "bleeding of the bladder" and suffered from frequent and painful urination. Urinalysis showed the urine to be alkaline and to contain blood and pus. During this time the defendant continued to treat only the fracture, but at the time of each visit he also examined the plaintiff's abdomen and observed her general condition. As to the abdominal condition, he acted only in an advisory capacity, leaving the treatment of that condition to the family physician. Finally, in April 1934 a urologist was called who caused roentgenograms to be made, disclosing that the bone peg had migrated into the bladder. According to the record, the peg was lodged completely within the bladder and its point of entry had become walled off by proliferative tissue.¹ Following an operation to remove the peg a complete recovery ensued. The patient then sued the defendant and from a directed verdict for the defendant she appealed to the Court of Appeals of Kentucky.

The plaintiff, while admitting that the fortuitous lodging of the bone peg in the bladder was not due to any fault of the defendant, claimed that he was negligent in failing to discover sooner that the peg had migrated. There was medical testimony to the effect that, even if the migration of the peg had been detected earlier, it would have been inadvisable to remove it until it had become free of the femur or, if it had entered the bladder, until it had become walled off in order to prevent extravasation of urine and the setting up of a lethal sepsis. The defendant, called as a witness by the plaintiff, testified that any examination of the patient, other than the type he made, would have been to her detriment rather than to her benefit, that it was inadvisable to disturb the patient on

1. Grant, Owsley: An Unusual Foreign Body (Bone Peg) in the Bladder, J. A. M. A. 107: 1632 (Nov. 14) 1936.

account of the condition of her hip and because of her excitability. He further testified that although he discovered in January 1934 that the peg was no longer in the bone, he was justified in presuming that the migration would be outward, not inward, because, as he testified, "there is no case on record where any ever worked in." He would not have been justified, he said, in moving the patient, jeopardizing the union that had already taken place, in order to take a roentgenogram to discover something that had never been known to happen before.

The location of the peg in the tissues, said the Court of Appeals, before it entered the bladder as well as after it completed its tour, could have been detected by a roentgen examination. The fractured hip and its cure were, however, of first importance. As long as the abdominal condition was not obviously impairing the plaintiff's health or life, it was the defendant's duty to allow the family physician's treatment thereof to be continued until a roentgen examination could have been made and an operation performed to relieve the abdominal condition without interfering with the healing of the fracture. At the time when the peg was in the femur or was passing into the bladder, and not entirely within it, an operation to remove it was not only inadvisable but perilous to the patient's fractured hip and to her health and life. If the defendant, therefore, by a roentgen examination or otherwise, had sooner located the peg, such discovery would not have justified its removal nor would such examination have alleviated the pains suffered by the patient. The fact that a sedative had never been needed to relieve the patient's pain tended to establish, the court thought, the soundness of the defendant's judgment not to sacrifice the treatment and cure of the fractured hip in order sooner to discover the cause of those pains.

Negligence on the part of a physician cannot be presumed from evidence merely of pain and suffering, of failure to effect a cure or to obtain the result expected by the patient, of poor or bad results, of bad judgment, or of the presence of infection. The doctrine of *res ipsa loquitur* has no application. The physical appearance of a patient following a physician's treatment and the patient's declarations with respect to the existence or severity of pain may be proved by lay testimony; whether or not the negligence of the physician was the primary cause thereof must be established by expert testimony. Where expert testimony discloses nothing more than an error of judgment, the physician is not guilty of malpractice. In the present case, the court concluded that the plaintiff had failed to prove that the defendant had left undone something that he should have done or that he had done something that he should not have done. Accordingly, the court affirmed the judgment for the defendant.—*Meador v. Arnold* (Ky.), 94 S. W. (2d) 626.

Malpractice: Alleged Puncture of Common Bile Duct During Removal of Gallbladder.—The plaintiff in 1931 suffered from a "gallbladder attack." A second attack occurred in July 1932 and a third late in December of that year. The defendant-physicians attended the plaintiff, and roentgenograms taken in August 1932 and in January 1933 showed the presence of gallstones in the gallbladder. An operation was performed by the defendants June 6, 1933, and the gallbladder removed. During this operation, it was contended, a probe was inserted through the walls of the common duct and that thereafter bile escaped into the abdominal cavity, resulting in the subsequent illness of the plaintiff. The trial court, in a malpractice suit instituted by the plaintiff, directed a verdict for the defendants. The plaintiff died during the pendency of her motion for a new trial, and the administratrix of her estate was substituted as party plaintiff. The motion for a new trial was denied and the administratrix appealed to the Supreme Court of Minnesota.

Concededly, said the Supreme Court, the defendants were qualified and experienced physicians and surgeons in good standing and possessed at least the average skill of physicians and surgeons practicing in their community. While a physician is not an insurer of a cure or good results, he is required to possess the skill and learning possessed by the average member of his school of the profession in good standing in his locality and is required to apply that skill and learning with due care. Two medical experts testified for the plaintiff but neither stated that a puncture or opening was made in the common duct by

the defendants during the operation for the removal of the gallbladder. Neither expressed an opinion as to whether the ailments and complications suffered by the plaintiff following the operation resulted from an operative puncture of the wall of the common duct or from a failure of the defendants to exercise proper care and skill as surgeons. One of these witnesses testified that in his opinion the plaintiff's condition was due to infection of the biliary tract and that such conditions result "time and again" in cases in which the operating surgeon has exercised all due care and skill, and that the plaintiff's condition was not indicative of any lack of skill or want of care on the part of the operating surgeons. The other witness testified that the plaintiff's condition indicated gallbladder disease and possible infection in the biliary tract prior to the date of the operation and that there was some chronic inflammation in the gallbladder beginning as early as 1931, when the plaintiff experienced her first attack. Both experts agreed that a gallbladder operation was serious and sometimes results in complications or death in spite of the exercise of the best skill and care on the part of the operating surgeon. The evidence as a whole, in the opinion of the court, was insufficient to sustain a finding that the infection was caused by any failure of the defendants to exercise the care and skill required of them.

In malpractice cases, proof of causal connection between the injury and the alleged neglect of the physician must be something more than consistent with the plaintiff's theory of how the claimed injury was caused. The burden is on the plaintiff to show that it is more probable that the harm resulted from some negligence for which the defendant-physician was responsible than in consequence of something for which he was not responsible. No presumption of negligence arises from the fact that an operation or treatment by a surgeon or physician does not result in a cure. The doctrine of *res ipsa loquitur* is not applicable. The plaintiff having failed to meet the burden of proof imposed on her, the trial court did not, in the opinion of the Supreme Court, err in directing a verdict for the defendants.—*Yates v. Gamble* (Minn.), 268 N. W. 670.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Vascular Complications of Polycythemia.—About one third of the ninety-eight patients with polycythemia vera that were observed at the Mayo Clinic from January 1929 to 1936 had vascular complications, which Norman and Allen state indicates that polycythemia was responsible for the vascular diseases in most instances since the latter affect a much smaller proportion than one third of all patients of similar ages and sex. Moreover, this hypothesis is logical, as the conditions in the blood are those which produce an increased tendency to thrombosis. The situation is not so clear in relative polycythemia, in which the disturbances in the blood are frequently minimal. It is probable that the changed status of the blood is not responsible for the vascular lesions in the majority of cases of relative polycythemia. For example, polycythemia is rare in thrombo-angiitis obliterans. Naturally, the fundamental disturbance may, in some obscure manner, produce thrombo-angiitis obliterans and relative polycythemia. These observations regarding thrombo-angiitis obliterans apply to arteriosclerosis obliterans, and with less certainty to erythromelalgia and vasospastic neurosis. Phlebitis and cerebrovascular hemorrhage or thrombosis may have resulted directly from polycythemia, but the authors have no evidence that this is so. It is advisable to treat polycythemia vera if for no other reason than to prevent vascular complications. If the many vascular diseases are viewed with the suspicion that polycythemia vera exists, it will be found in at least a small percentage of cases. It appears that arteriosclerosis obliterans and thrombo-angiitis obliterans respond in a better manner to treatment if polycythemia which may be present is treated actively.

Heritage of Clinical Laboratory. Vivian Herrick, University, Ala.—p. 53.

Laboratory Recognition of Monilia.—Snow points out that, besides the fact that Monilia may be associated with a variety of disease processes, some organisms of this group may be found in the throat, mouth and intestine of healthy individuals. Moreover, laboratory contamination by Monilia may occur. Therefore it is advisable to make repeated examination of pathologic material in order to make sure that the parasites can be found more than once. This will strengthen the assumption that the organisms are present in the lesion. In an

examination of sputum for bronchomoniliasis, for example, contamination from the mouth must be eliminated as far as possible. Early diagnoses are important, as it is possible for the parasite to invade the blood stream with the production of metastatic abscesses. The fact that the practitioner sometimes confuses a membrane caused by a monilia with a diphtheritic membrane also emphasizes the necessity for the laboratory technician to have a well defined knowledge of this organism. The isolation and identification procedures applicable to the study of Monilia are generally tedious and slow. Not only is it necessary to consider such morphologic features as spore formation, size and appearance of mycelium, size, shape and location of moniliform clusters, but also there should be correlation with the fermentation tests.

Adrenal Cortex Therapy in Vomiting of Pregnancy.—Freeman and his associates treated seventy-eight pregnant women for nausea and vomiting with adrenal cortex after the remedies commonly used for this condition failed. The less severe cases of nausea and vomiting were treated exclusively with tablets; the more severe cases were treated at first with parenteral injections. Of the forty-seven treated patients with less severe nausea and vomiting, only two failed to receive any benefit. There were fifteen patients who had severe nausea and vomiting and sixteen patients who were classed as having pernicious vomiting. A cure was effected with the parenteral treatment in every instance within from three to five days. It is important to note that in no instance did the condition of nausea and vomiting become more severe, necessitating the interruption of pregnancy. In the more severe cases of nausea and vomiting, the body fluids and vitamins were replaced as rapidly as possible. In patients in whom the ketosis did not clear as rapidly as the clinical symptoms, insulin was added to the intravenous medication. No contraindications of the use of adrenal cortex have been encountered. The patients, who were merely nauseated or who vomited but rarely or at regular intervals, were told to take one tablet (0.2 Gm.) three times a day, about one-half hour before their regular meal. If at the end of a week their symptoms had not completely ceased, the dose was increased up to six tablets a day. For patients who vomited at irregular intervals or who vomited everything taken by mouth the contents of one ampule (1 cc.) of adrenal cortex were injected three times a day, about one-half hour before mealtime. The injections were continued for three days after the disappearance of all signs of vomiting; then one ampule was replaced by one tablet on each successive day, so that by the end of the sixth day after cessation of vomiting the patient was receiving three tablets a day and no injections. The tablets were then continued until 100 had been taken.

Emphysema of Artificial Pneumothorax.—Korol states that in certain cases of artificial pneumothorax the treated lung presents transparent areas which on the roentgenogram appear as bright as or brighter than the air in the pneumothorax cavity. In practically all cases described in the literature there was a pleural exudate of long duration. In the majority of cases there were signs of bronchial fistula, such as high pressures in the pneumothorax, purulent effusions rich in tubercle bacilli or attacks of spontaneous pneumothorax. In all the cases the lung collapse was incomplete, owing to adhesions that existed prior to the induction of the pneumothorax. The author believes that this phenomenon is caused by (1) a progressive pachypleuritis, which thickens the pleura overlying the pneumothorax but spares the treated lung owing to preexistent adhesions, (2) areas of vicarious emphysema in the adherent lung and (3) air pockets between strands of adhesions or between the lung and the visceral pleura.

Osteomyelitis of Frontal Bone.—Adson and Hempstead employ a procedure that prevents the usual deformity that follows an operation on the frontal sinus and permits the removal of all sequestrums and thorough drainage of the frontal sinus by removing the posterior table of the sinus. The surgical

principles include (1) adequate drainage of the frontal sinus, (2) removal of pus, necrotic bone and all white dead bone, (3) preservation of the periosteum if possible and (4) concealing the incisions of the scalp within the hair line. The last principle is accomplished by employing a coronal incision placed in the hair line. The incision should extend through the scalp to include the periosteum. It is not only important to remove the sequesterum, the island of necrotic bone, but it is likewise important to remove the adjacent dead bone even though it involves both tables of the skull. If a small island of avascularized bone remains it will act as a source for continuous drainage and cause further extension of the infective process. However, it is not necessary to remove living or bleeding bone. After complete sequestrectomy and the exenteration of the frontal sinus, the entire surgical field is washed with pure tincture of iodine. The frontal sinus is packed with gauze soaked in tincture of iodine. Additional strips of similar gauze are laid in the bony channel, and all are brought out through the line of suture. Extraperiosteal infection and infection of the scalp, if present, are drained by incisions through the periosteum from underneath the flap. Injury to the periosteum covering the defect over the craniotomy should be avoided, since the preservation of the periosteum stimulates the formation of new bone and the filling of the defect. The gauze drains are shortened daily and are completely removed by the third postoperative day. The removal of necrotic bone, the complete posterior exenteration of the frontal sinus and the free use of the tincture of iodine result in primary healing of the operative wound. Extensive sequestrectomy as employed at the Mayo Clinic has been used innumerable times for other osteomyelitic processes involving cranial bones. It has proved to be much more effective in cleaning up an extensive process than has drainage by a mere stab wound and the curettement of localized regions. Abscess of the brain invariably develops if improper drainage is instituted or if the infection is allowed to continue.

Clinical Study of Silicosis.—On the basis of a clinical investigation of 203 gold miners, Moore and Kelly find that it may be possible to recognize the miner who will develop silicosis, before the appearance of the usual signs, by lowered basal metabolism and pulse rates. Thyroid therapy may possibly not only prevent the development of silicosis but also

arrest its further progress and possibly reduce to some extent the degree of fibrosis already existing. Social and living conditions and diet are quite uniform among miners and evidently do not affect the development of silicosis. There was no evidence to show that liver, kidney or heart disease was associated with dust inhalation. A large proportion of silicotic patients have shortness of breath in varying degrees. Those studied had a lowered basal metabolic rate and slow pulse, which might be a compensating factor in reducing cardiac output with lessened heart strain and account for the large number of normal-shaped hearts in cases of longstanding silicosis. This is contrary to what one would expect in the presence of diffuse lung fibrosis. The presence of definite evidence of heart disease in a silicotic patient disabled from shortness of breath would certainly point to the fact that part of the disability is due to heart disease. The authors, however, know of no way to determine what proportion of the disability should be apportioned to one or other cause of the disability.

Size of the Heart After Coronary Thrombosis.—Palmer bases his clinical observations on the incidence and cause of cardiac enlargement on an analysis of 200 cases in which the attack was survived at least three months. The size of the heart was determined by x-ray study in every case. It invariably consisted of fluoroscopy in the anteroposterior and right and left oblique positions, frequently supplemented by orthodiagram and/or teleroentgenogram. Cardiac enlargement was found in 128 (64 per cent); thirty-two cases in which the report was "enlargement doubtful" were not included in this percentage but were classified as normal. By far the most important factor causing enlargement proved to be hypertension, which was held to be the single or predominant cause in more than 80 per cent of all cases with enlargement. Disease of the coronary arteries, either the actual thrombosis with its resulting infarction or the underlying arteriosclerosis, led to increase in the size of the heart in a total of eleven cases. No example of so-called acute dilatation of the heart was discovered among twenty-seven patients examined within a month of the attack. Congestive failure, which was not seen in hearts of normal size, seldom led to an appreciable increase in the degree of enlargement. About a third of the patients (36 per cent) failed to show or to develop enlargement, though observed over periods averaging more than three years following the first attack of coronary thrombosis. This number included several with recurrent attacks.

Water Metabolism.—Collier points out that abnormal losses of fluid, such as through vomiting, diarrhea, drainage from fistulas or exudations from large ulcers, are frequently of huge volume and must be carefully measured, recorded and replaced. Such losses, continued over a number of days and inadequately restored, will often lead to dehydration in spite of what appears to be a generous intake of fluid. A negative water balance should always be suspected and eliminated whenever dealing with cases of oliguria or anuria of no obvious cause. In order to maintain the water balance of a patient who cannot use his gastro-intestinal tract, 2 liters should be allowed for the loss through vaporization, 1.5 liters for the urine and to this a quantity equal to whatever amount the patient is vomiting or losing otherwise should be added. Secondly a dehydrated patient should be given fluid equal to 6 per cent of his body weight and then treated as one whose water balance is being maintained. Loss from the gastro-intestinal tract should

be replaced by physiologic solution of sodium chloride and the remainder of the fluid given as 5 per cent dextrose in distilled water.

*Use of Para-Amino-Benzene-Sulfonamide or Its Derivatives in Treatment of Beta-Hemolytic Streptococcal Meningitis. F. F. Schwenker, F. P. Clason, W. A. Morgan, J. W. Lindsay and P. H. Long, Baltimore.—p. 297.

Treatment of Beta-Hemolytic Streptococcus Meningitis.—Schwenker and his collaborators used sulfanilamide or its derivatives in the treatment of four cases of meningitis due to beta-hemolytic streptococci. Two of the patients had a primary otitic focus and one a traumatic focus (craniotomy wound), and in the fourth no purulent focus was discovered. In three patients surgical intervention (mastoidectomy, exploratory craniotomy) accompanied therapy with sulfanilamide or its derivatives. Three patients received intraspinal therapy with these chemicals while, in the other patient, oral therapy alone was used. Three patients recovered and one died. It appears that sulfanilamide or its derivatives offer the possibility of a specific chemotherapeutic approach to the treatment of beta-hemolytic streptococcus meningitis. A combination of oral and intraspinal therapy seems to deserve a thorough trial. If the patient is not nauseated and can swallow, treatment should be started with sulfanilamide by mouth and also by the intraspinal route. Tablets are used for oral administration. The total dose for the first twenty-four hours is calculated on the basis of three tablets (1 Gm.) to each 20 pounds (9 Kg.) up to 100 pounds (45 Kg.) of body weight. For adults with acute infections the authors believe that 5 Gm. of this substance represents the maximal daily dose. This total amount is divided into four doses given at intervals of six hours. In preparing the drug for clinical use it is their practice to dissolve 0.8 Gm. in 100 cc. of physiologic solution of sodium chloride which has been brought to the boiling point and then cooled to about 90 C. Such 0.8 per cent solutions of sulfanilamide may be used intrathecally. The general practice in administering the drug intrathecally should closely follow that recommended for the use of antimeningococcus serum in meningococcal meningitis, namely, that rather complete spinal drainage by lumbar puncture should be instituted and then from 15 to 25 cc. of a warm, freshly prepared, 0.8 per cent solution of sulfanilamide should be permitted to flow in by gravity. If the patient cannot swallow tablets, parenteral therapy by the subcutaneous route with either hydrochloride of 2:4 diaminoazo-benzene-4' sulfonamide or an 0.8 per cent solution of sulfanilamide in sterile physiologic solution of sodium chloride may be instituted. With the former solution, 1 cc. per pound of body weight constitutes the total daily dose. This is divided into four equal doses given at intervals of six hours. If 0.8 per cent sulfanilamide solution is used, it should be given as a hypodermoclysis in the following amounts: For patients weighing up to 40 pounds (18 Kg.) 100 cc., from 40 to 80 pounds (18 to 36 Kg.) 200 cc., from 80 to 120 pounds (36 to 54 Kg.) 300 cc., and for those weighing more than 120 pounds 400 cc. in twenty-four hours. Therapy should be continued at the advised level until the spinal fluid has been rendered sterile for at least forty-eight hours and a marked general improvement in the patient's condition has occurred. At this point the intraspinal therapy may be discontinued and the amount of the drug given by mouth reduced by one third. Adequate oral therapy should be maintained until the patient is entirely well. Surgical procedures designed to eradicate septic foci are indicated in streptococcal meningitis as an adjunct to specific therapy, but extensive surgical intervention should not be resorted to until the infection has been brought under control by specific therapy.

- *Interpretation of Gastric Pain. F. M. Sherman, Owensboro.—p. 215.

Interpretation of Gastric Pain.—Sherman confines his discussion to pain in the upper part of the abdominal region or gastric area. The painful diseases of the stomach belong, according to nomenclature, to three main groups: inflammations, ulcerations and new growths. Stomach pain is nearly always epigastric, occasionally it may be referred to the left or to the right, but as a rule it is situated in the pit of the stomach. In inflamed conditions of the stomach the pain is likely to appear soon after eating. There is no group of digestive diseases that gives the same degree of periodicity and rhythmicity to pain as does peptic ulcer. Gastric ulcer nearly always gives pain within one to two hours after taking of food, while duodenal ulcer is somewhat later. In every instance one must rule out organic disease of the central nervous system. One of the commonest causes of pain in the epigastric region is gallbladder disease. It is responsible for more gastric disturbance, so-called indigestion and flatulence than anything else. Pancreatic disease in its chronic form resembles gallbladder disease in its annoying persistence. The relationship to food is not so clearly drawn as it is in gastric or duodenal disease. Situated on the posterior wall of the body, the pain is frequently referred to the back, although it may persist in the epigastrium. Splenic disease may be an exceedingly painful condition, but the pain is usually located in the left hypochondriac region. Other causes of pain in the gastric region may be enumerated as follows: epigastric hernia, postoperative hernia, adhesions, perigastritis, diverticulitis (more particularly of the duodenum), hepatitis, retroperitoneal growths, tubercular obstructions and many lesser conditions. There are many disorders causing epigastric pain that are not due to stomach disease which may exist and so affect the stomach directly or reflexly that the clinical picture may suggest stomach disease rather than the true condition. Esophageal disease frequently becomes manifest on deglutition, stomach disease as ulcer about two hours after eating, duodenal disease about three or four hours after taking food, and gallbladder, pancreatic and hepatic conditions four or five hours after eating, while colon disease manifests itself during defecation. Genito-urinary disease is usually manifested during the act of micturition, and evidence of spinal, skeletal

or muscular disease when active function of the part involved is demanded. Other conditions that may be misleading are influences through the blood stream, the various allergic conditions, acute infectious diseases, such as measles, lead poisoning, and undulant and rheumatic fevers. Herpes zoster may mimic an acute abdominal condition in its early stage, before the appearance of the characteristic rash; ordinarily the pain and other symptoms are not sufficiently marked to suggest an intra-abdominal or gastric lesion.

Intrathoracic Neurofibromas.—Epstein reports the case of an Armenian girl, aged 4 years, with large tumors of the chest, admitted to the Boston Floating Hospital in the winter of 1935. Her past history was negative up to December 1933, when a small lump in the right axilla was noted. Roentgenograms revealed a large thoracic shadow in the right apical region, and a diagnosis of probable neurofibroma was made. Permission to perform an operation was refused at this time, but she was rehospitalized later because of the persistence of the chest mass. Clinically the patient presented no unusual features. Operation was performed in January 1936 under basal tribromethanol anesthesia and intratracheal ether-oxygen with differential pressure. A curved incision was made posteriorly, releasing the scapula, which was retracted anteriorly. There were large neuromas beneath the skin and in the substance of the trapezius and rhomboid muscles. When the bony wall of the chest had been exposed, the perforating branches of the intercostal nerves were found to be grossly enlarged by fusiform swellings. The second to fourth ribs were divided and the pleural cavity was opened. The apex of the chest was filled by a large tumorous mass that lay close against the vertebral column and extended laterally and anteriorly in such a way that it impinged on the chest wall. The spinal nerves entered this mass directly from the vertebral foramina. These roots were severed and a large mass of neurofibromatous tissue was removed. The first rib was left intact to protect the subclavian vessels and the important cords of the plexus, but, in view of the subsequent partial palsy of the ulnar and median nerves, the first dorsal root of the plexus was injured, presumably, by traction. After the tumor had been removed, the chest wall was closed in layers without drainage. Within two months after the operation the mass in the neck increased in size. The presence of a firm "ropy" tissue was observed, extending from the right axilla along the course of the median nerve to the anterior cubital fossa and thence to the midwrist. This tissue was most pronounced in the upper part of the middle arm, where a hard mass was felt. A partial paralysis of the median and ulnar nerves occurred on the right side with a

corresponding atrophy of the thenar and hypothenar eminences. The skin of the right palmar surfaces was glossy and dry in comparison to that of the left. There was a slight improvement in the quality of the pulse. The right eyeball protruded slightly and there was also a slight ptosis of the right lid and persistence of the miosis. Roentgenograms showed that the mass in the left side of the chest had increased in size. The mediastinum was still very wide in the region of the operation, and the heart was in the median position.

Testing Superficial Blood Circulation for Determining Level of Amputation.

—In the examination of the superficial circulation for determining the proper level of an amputation, Nyström has employed a method which causes an irritation of such intensity on the capillaries and small arteries that the greatest possible hyperemia is produced. The method is based on brief freezing of the skin with the aid of carbon dioxide snow. Fluid carbon dioxide is sprinkled in a little bag of velvet or leather, where it gathers in the form of snow. The snow is shaken out in a metal tube with a diameter of about 20 mm. and packed in a firm rod with the aid of a metal piston and a mallet. The ice rod is pressed against the skin for three seconds successively over the area to be tested in spots at a distance of from 5 to 10 cm. from each other. The procedure begins at the most distal point to be tested and continues upward. For comparison the same procedure is repeated on the corresponding parts of the other limb. In normal cases the white frozen spots of the skin thaw to normal consistency and color in about one minute. After another minute the hyperemia sets in and soon becomes maximal. The speed with which the hyperemia sets in and the grade of its intensity afford a certain guide as to the condition of the arterial supply. Also when the maximal effect is reached the hyperemic spot may be compressed with the finger for five seconds, then hastily removed, and with the aid of a stopwatch the seconds that elapse until the spot has again reached its maximal filling with blood are counted. Under normal conditions and in a horizontal posture,

the refilling of blood takes an average time of from one to two seconds. The return of the blood to the anemized spot is of a flaming character. With a bad arterial supply the time may be extended to ten, fifteen or twenty seconds or more. In normal conditions an edema begins to appear in the spot after from ten to fifteen minutes and soon brings about a slight, sharply limited elevation of the skin. As to the practical application of the results of the examination, the author first tried to make the amputations immediately above the lowest spot that showed a good hyperemia and wheal formation, but later he found it safer to choose a somewhat higher level, from 10 to 15 cm. above the lowest spot, with good response of hyperemia and edema.

Postoperative Wound Separation.—Fallis states that postoperative wound rupture occurred in fifty of 7,903 consecutive laparotomies performed at the Henry Ford Hospital, an incidence of 0.64 per cent. It is the practice to perform secondary closure immediately. This is possible if the patients are moved to the operating room and operated on in their own beds. The use of local procaine hydrochloride infiltration plus subcostal block provides adequate relaxation if general or spinal anesthesia is contraindicated by the patient's condition. Forty-nine of the fifty patients had a secondary closure done. A seasonal variation is shown in the series. Multiple operations had been performed in 73.5 per cent of the cases. In 55 per cent of the cases the operation had lasted one and one-half hours or longer. Stay sutures of silkworm-gut or silver wire were used in 36.5 per cent. The clinical picture in the noninfective cases suggests an allergic reaction. The mortality following secondary closure was 34 per cent.

Deficiency Disease from Poor Gastro-Intestinal Absorption.

—During the last fifteen years, Davis encountered eight patients who had well marked deficiency syndromes of the sprue type and in whom he made a diagnosis of nontropical sprue. The manifestations varied considerably in each case, which suggests that the underlying cause must not be exactly the same in all cases. On the other hand, the differences might be the result of the same factor operating on different individual constitutions. It is a dietary deficiency syndrome, which may be primary or may be secondary to chronic gastro-intestinal lesions. In the treatment of these patients a diet high in protein content but low in fermentable sugars and cellulose residue will make their abdomens more comfortable. Their carbohydrates may be made up with milk and lactose or possibly with bananas or banana powder. Liver extract or concentrated vitamin B complex may be helpful. If absorption is not adequate, the former may be given intramuscularly. Adequate amounts of calcium are indicated and again the injection method of administration may be advantageous. Some of the patients will have so much degeneration of their intestinal mucosa that it cannot be restored to function and the patient literally starves to death, even though he is ingesting adequate quantities of foodstuffs. Certain of these patients will be found to have localized intestinal lesions in the early stages which may be amenable to surgical resection.

Gastric Acidity in Children.—There appears to be no evidence that a congenital failure of gastric secretion is responsible for the development of the simple iron deficiency or nutritional anemias of infancy. Stewart therefore suggests that these anemias are the result of a pure deficiency in iron intake, which may date from before birth and is considerably influenced by prematurity. Once the anemia is established the general health of the child is lowered, intercurrent infections frequently occur and the acid secretion of the stomach is generally reduced. The absorption of the available iron is thus further impaired and a vicious circle is established. It is probable that infective states, particularly enteritis, play a part in the etiology of the iron deficiency anemias of childhood by causing chronic gastritis with suppression of acid secretion as suggested by Faber, but this point requires further investigation. It occurred to the author after completing the present investigations that, as so many of these patients are either premature infants or twins, a test meal examination of such children during the early weeks of life would be of interest. So far nine infants have been thus examined. At least a small amount of free acid was present in every case in spite of the comparatively high buffer action of the milk, which was shown by the total acid always reaching a considerably higher level. The average maximal free acid for the nine cases was 21.5 per cent of tenth normal solution and the average maximal total acid was 43.8 per cent of tenth normal solution. This preliminary investigation appears to support the foregoing contentions.

*Pyknolepsy: Report of Case. H. L. Parker.—p. 70.
Radiology in Diseases of Gallbladder. S. J. Boland.—p. 73.

Pyknolepsy.—Parker states that pyknolepsy is rare. Certain features of pyknolepsy tend to separate it from the more common clinical syndrome of petit mal. Girls are more commonly affected and the family history is usually free from epilepsy, insanity and kindred diseases. The onset is between the age of 4 and 10 years, and while in the case reported the disease came on gradually, more usually it is abrupt and overwhelming from the beginning. There is a stereotyped character of the attack as in petit mal such that it rarely changes its character through-

out the course of the disease. The characteristic feature, however, is its extreme brevity, so that the whole attack is a matter of a few seconds and considerably shorter than the average course of petit mal. Another distinguishing feature is the extreme frequency with which these attacks occur. They may reach the striking total of a hundred a day. The degree of loss of consciousness is slight and is perhaps the principal feature. The patient never falls and may continue to carry out in a more or less efficient manner activities originally engaged in. While petit mal shows but little response to antiepileptic drugs such as bromides and phenobarbital, pyknolepsy does not respond at all. There are certain reasons why it is important to recognize pyknolepsy even though its existence as a clinical entity may be doubted. Some months or years may be necessary for this recognition, and caution must be used before reaching such a conclusion. In spite of the tremendous frequency of the attacks, there is little or no mental deterioration. Pyknolepsy runs a natural course and disappears at or about puberty as mysteriously as it came. In this it stands out supreme among the epilepsies as a benign affliction.

*Nature of Causative Agent of Rous Fowl Sarcoma. E. M. Fraenkel and C. A. Mawson.—p. 282.
Effect of Vitamin E Deficiency on Thyroid. M. M. O. Barrie.—p. 286.

Nature of Causative Agent of Rous Fowl Sarcoma.—Fraenkel and Mawson have confirmed the fact that it is possible to deposit the agent from extracts of Rous sarcoma by centrifugation at 15,000 revolutions per minute, but they have been unable to obtain satisfactory correlation between the number of elementary bodies in different active preparations and the infectivity of the extracts. The supernatant after centrifugation is usually much less active and contains many fewer ultramicroscopic particles than the original extracts, but the infectivity of material concentrated many times on the centrifuge is seldom so active as would be suggested by the enormous numbers of elementary bodies present. Their impression is that the tumor-producing activity of Rous extracts is associated with material which can be deposited at 15,000 revolutions per minute, but they believe that only a small proportion of the elementary bodies visible in the extract can be associated with that activity, and they would emphasize that the possibility that the active agent is adsorbed on the surface of such particles cannot be excluded. The hypothesis of a purely chemical agent of the Rous sarcoma seemed to be confirmed when Jobling and Sproul claimed that repeated injections of an acetone extract of fresh Rous sarcoma tissue would produce similar tumors. Unless their technic has differed in some way the authors conclude that the results of Jobling and Sproul were due to fine suspensions of active material in their solvents. This possibility is enhanced by the fact that in their own experiments with dried powders the activity remained in the residue after extraction. This conclusion is disappointing from the point of view of the chemical hypothesis, but it does not exclude the conception suggested by virus-enzyme, as such a substance might be expected to be insoluble in acetone.

*Influence of Bodily Strain on Heart of Athletes: Cardiographic Study. M. Rosnowski.—p. 133.
Acrocyanosis. R. Cavalcanti.—p. 141.

Influence of Strain on the Hearts of Athletes.—Rosnowski has taken 203 electrocardiograms of skiers and marchers immediately before, during, and twenty-four and forty-eight hours after the strain. He took accurate measurements of the rhythm and the amplitude of the waves in all three derivations and made exact figures of each particular period of cardiac phases in the second derivation. All athletes have a bradycardia, but after a prolonged effort the duration of heart beats becomes shorter, often by 60 per cent of the space between the P and T waves. The space between the R and T summits goes down 16.4 per cent and the T wave itself 10 per cent. The P wave (auriculoventricular) is not always the same, but its average is generally increased 12 per cent. Concerning the rhythm there was a partial or sometimes even a total blockage of the bundle of His (lengthening of PR). Three subjects had a ventricular extrasystole, which disappeared in two after the strain but persisted in one. Four had a nodal arrhythmia before the strain, which disappeared after it and reappeared from twenty-four to forty-eight hours later. Sinusoidal arrhythmia is most frequently encountered. The autonomous nerves exercise a great influence on a strained heart, subjecting it to a sympathetic tonus during exercise and to a vagotonus soon after it. The development of the auriculoventricular waves (T) soon after the strain depend, according to the author, on the intensified work of the heart muscle. The enlarged T wave signifies a good functional adaptability of the ventricles, considering the energetic return of the cardiac muscle to a state of rest. The diastole or ventricular intermission is longer in paving the way for the succeeding systole, whereby the left ventricle carries the brunt.

- *Against Decortication of Hydatid Cysts. Costantini and Oulié.—p. 449.
Pain Following Dental Extraction: Rôle of Sympathetic System in Pathogenesis and Treatment. M. Dechaume.—p. 451.
*Benign Meningitis of Swineherds. G. Charleux.—p. 452.

Decortication of Hydatid Cysts.—Costantini and Oulié find the Russian method of operation on hydatid cysts rather dangerous. This method is practiced at Karkhoff and Professor Melnikoff states that the closed cystotomy transforms a parasitic cyst into a nonparasitic cyst, that, except for large cysts, cystectomy is the operation of choice and that cystotomy is the operation of necessity. While Melnikoff's statements are based on thirty-four cases, Oulié's experience with 164 hydatid cysts led him to different conclusions shared by some other Russian schools which, though regarding decortication of hydatid cysts as an ideal operation, consider it dangerous if the cyst is embedded in the parenchyma, which would necessitate a further resection of the pericystic tissue of the liver. To do so is useless, since after Daniliak the fibrous capsule could not cause dissemination of the disease. Its structure will not permit the parasite to vegetate there. The authors are therefore much in favor of the classic procedure, which in aseptic cysts consists of puncture, formolization, aspiration of the liquid and, if possible, of the vesicles, wide opening and removal of the parasite and of existing vesicles, verification that the pouch has been well emptied, closure of the opening at different points and fastening to the abdominal wall. In suppurated cysts and in those containing bile, marsupialization of the pouch is practiced. This operation will obviate the immediate danger of hemorrhage and will also do away with belated casualties to the peritoneum from an accidental opening of the cyst.

Benign Meningitis.—Charleux gives the description of an acute benign meningitis encountered mostly among fruit gatherers of Switzerland and Savoy. This disease attracted some attention recently because from 5 to 10 per cent of the students of the dairy farms in Berne fell victims to it. It was found to attack mainly young laborers who, besides gathering fruit,

are occupied in the making of cheese, the by-products of which are fed to pigs. These are probably the transmitting agents. The intermediary host is not known. The disease begins suddenly with chills and high temperature, coated tongue, vomiting, obstipation or diarrhea. The feces have the odor of pigs. Violent headaches and dull sensorium have often led to the diagnosis of typhoid or paratyphoid. Both torticollis and Kernig's sign are marked. The patient is often restless but shows no somnolence or delirium. There is often lymphocytosis but no change in mononuclears and polymorphonuclears. The diagnosis must be differentiated from tuberculous meningitis through the fact that the patient is well nourished and by considering the nature of his occupation. Furthermore, perspiration, cyanosis and slight eruption on the skin, added to the gastrointestinal symptoms, will facilitate the diagnosis. Lumbar puncture eases the headaches and seems to shorten the time of illness. Phlebotomy also gives good results, probably by reducing the cerebrospinal tension.

Acute Aleukemic Myeloblastic Leukemia: Case. Schnyder.—p. 316.

Pelger's Nuclear Anomaly of Leukocytes.—Stahel directs attention to the nuclear anomaly of the leukocytes, which was first described by Pelger in 1930. The segmentation of the neutrophils does not exceed two segments, and numerous staff cells appear in spite of the absence of an infectious state of irritation. The nucleus of all segmented cells has the same well rounded pear-shaped outline. The nuclear structure is surprisingly coarse and lumpy. These coarse outlines are found also in the staff cells. Pelger's anomaly was first regarded as a hereditary disorder, with dominant transmission, which had no particular significance for the health of the person, but a connection with tuberculosis was likewise suggested, for tuberculosis was repeatedly observed in families and individuals who had Pelger's anomaly. A review of the literature of the cases of Pelger's nuclear anomaly demonstrates the frequent concurrence with tuberculosis. Especial attention is given to two cases in which the bone marrow had been examined. Observations in these cases and observations after the injection of a bacterial protein preparation indicate a special mode of reaction of the bone marrow. A connection with tuberculosis seems likely, since it might elicit a special bone marrow reaction. It is possible that the defense against infections is impaired in persons with Pelger's nuclear anomaly.

Late Sequels of Gravidic Pyelitis.—Robecchi and Dodero studied the frequency of late complications in gravidic pyelitis and the type of lesions left by the disease. In a group of eleven women suffering from typical gravidic pyelitis five or thirty months previously, the urine, taken by catheterization of the ureters, was examined and an ascending pyelography was made. In eight of the patients there were late sequels consisting in the presence of leukocytes and bacteria in the urine and dilatation of the ureters and of the pelvis. According to the authors, the gravity and permanence of the sequels that take place in gravidic pyelitis depend on the time of duration of the acute phase of the disease. They are unrelated to the time that elapses between the control of the disease and examination

of the patient. The authors emphasize the importance of early examination and treatment in patients who suffered from the disease, especially in case of a new pregnancy, in order to prevent development of sequels by controlling the disease before establishment of permanent organic alterations.

Behavior of Testicle After Interruption of Vas.—Bertini unilaterally interrupted the deferent duct in rabbits and observed the testicle for five months after the operation. The latter does not cause changes of the seminiferous epithelium. The alterations produced by the operation are dilatation of the epididymis and atrophy of the epididymal epithelium. The testicle shows no atrophy, but the spermatogenic function is diminished. The testicular secretion, taken from puncture, showed the vitality of the spermatozoa to be good.

Action of Colloidal Carbon on Immune Reactions.

David gave intravenous injections of colloidal carbon to rabbits with experimental staphylococcal infection. He found that the substance does not produce shock and other complications. It acts by stimulating the organic reactions of defense (reticulo-endothelial system), increasing leukocytosis and the phagocytic power of the blood and putting the animal in condition to ward off infection. Hyperleukocytosis takes place within three or four hours after the injection without intermission of hypoleukocytosis (the so-called depressive phase of the leukocytes). As the leukocytes increase in number, their phagocytic activity is also increased.

Influence of Dextrose on Immunity.—Cotrufo states that hypodermic injections of an isotonic solution of dextrose during the course of a specific immunization stimulates development of the general immunity. The powers of agglutination and fixation of the complement of the blood serum increase by the nonspecific action of dextrose. The author's statement is supported by the results of experiments in rabbits in the course of immunization against typhoid. The immune reactions in the rabbits that were given hypodermic injections of dextrose in the course of immunization were increased in comparison to those of rabbits in which immunization without simultaneous administration of dextrose was carried on. According to the author, the results of his experiments show the advisability of administering dextrose alone or with a specific treatment in infections.

Charcoal in Puerperal Infection.—Peralta Ramos and Pelaez de Biondini resorted to intravenous injections of animal charcoal in puerperal infection. The patients were seriously ill with an endometrial localization of the infection and with or without retention of placenta. In four cases of the group there was septicemia. A daily injection of from 1 to 5 cc. of a 2 per cent solution of animal charcoal in distilled water was administered for six or eight consecutive days. The group included fifteen patients. The four patients suffering from septicemia died. In some cases the injection was followed by intense chills and high fever. In one case the injection was followed by grave shock. The authors conclude that the treatment may give satisfactory results in controlling puerperal infection of moderate intensity. It is not indicated in grave cases.

Vitamin C Deficit During Pregnancy. G. Gachtgens and E. Werner.—p. 475.

Pregnancy Toxicoses and Tumors.—Von Bud maintains that the pregnancy toxicoses are caused by focal toxins, for the therapeutic results he obtained with the extirpation of foci corroborate this. He points out that in a paper on convulsive eclampsia he called attention to the effects of focal toxins on the nervous system. Moreover, on the basis of his studies on eclampsia without convulsions, on ileus and pyelitis, and on the basis of clinical observations, he is of the opinion that the cause of puerperal fever is to be found in a disturbance of the nervous system, which in turn is elicited by focal toxins. On this basis could be explained also the diseases of the ovum and of the placenta and the congenital predisposition for disease. Malignant and benign tumors, which developed after some conditions of irritation of the nervous system (eclampsia) and after paralytic-atonic pregnancy toxicoses (ileus and pyelitis), directed the author's attention to the fact that the focal toxins not only exert an irritating effect on the nervous system but may lead also to tumor formation by way of trophic disturbances. He illustrates this possibility with four cases.

*Fluorescence Microscopy of Leprosy Bacteria in Nasal Mucus and in Blood. P. Hagemann.—p. 514.
Treatment of Rosacea. S. Bommer.—p. 518.

Quinine in Treatment of Pneumonia.—Ballmann points out that the injection of quinine permits an energetic attack of the cause of pneumonia without disturbing and moving the patient. At his hospital more than 2,000 patients were given injections of quinine preparations and the number of cases in which complications developed was small. He shows that the injurious effects of the injection of quinine preparations which have been reported in the literature could have been avoided if the necessary caution had been observed. He cites cases in which brachial nerves were paralyzed because inexperienced assistants or nurses had injected the quinine preparation into the arm. Quinine preparations, he says, should be injected by the physician himself and only into the gluteal muscle with a sufficiently long needle. If these rules are observed, the treatment of pneumonia with quinine injections is without danger and, compared to the merely symptomatic treatment, it shortens the disease process and reduces the number of complications and the mortality rate.

Fluorescence Microscopy of Leprosy Bacteria.—Hagemann describes a new method for the demonstration of microbes, particularly for the visualization of the causal organism of leprosy in the nasal mucus or in the thick drop blood preparation. The micro-organisms are stained by means of solutions of fluorescent substances, the so-called fluorochromes, and are then visualized by the fluorescence that develops under the influence of ultraviolet irradiation, under the special microscope. In order to detect leprosy bacilli, the specimen is treated for fifteen minutes with an aqueous solution of berberine sulfate containing phenol; then it is washed for from ten to fifty seconds with hot water (from 60 to 70 C.) and examined under the fluorescence microscope. The bacilli appear as yellow to green luminant rods, which stand out in contrast

to the weaker fluorescing background. The author concludes that this method of demonstrating the organisms is in many respects superior to others. Moreover, fluorescence microscopy can be used also for the demonstration of tubercle bacilli, trypanosomes, plasmodia and so on.

*Unilateral Honeycombed Cavity of Lung on Bronchiectatic Basis. K. Sixt.—p. 184.

*Quantitative Evaluation of Tuberculosis from Functional Blood Picture. O. H. Bucher.—p. 189.

Unilateral Cavity of Lung on Bronchiectatic Basis.—Sixt reports the clinical history of a young woman who for several years had received treatment in hospitals and sanatoriums on account of suspected open tuberculosis. However, on the basis of the long previous history, the extensive and unilateral pulmonary process in the presence of a relatively favorable general condition, the always negative sputum examination, the twice negative animal experiments and the outcome of the contrast substance filling tests, the pulmonary disorder was finally recognized as extensive bronchiectatic cysts of the right upper lobe with atelectasis and pleuritic changes in the left lower lobe. Tuberculosis could be excluded. Syphilis, which also occasionally produces aspects similar to those observed in this patient, could be ruled out on the basis of negative serologic reactions and of the absence of syphilitic symptoms. The author says that he reported this case not only because it is interesting, but particularly to stress the necessity of a thorough and careful examination before a patient is placed in a hospital or sanatorium for tuberculous patients.

Evaluation of Tuberculosis from Blood Picture.—Bucher thinks that the quantitative and qualitative changes in the leukocytic blood picture, which were investigated by Arneth, Schilling and others, may be regarded as a definitely established morphologic entity and maintains that they are suitable for the diagnosis of the tuberculous process from the blood. He points out that Hoefflin and Stanley succeeded in demonstrating in experiments that by counting the monocytes and the neutrophils with nonsegmented nuclei it is possible to estimate the intensity of a tuberculous infection. This idea of Hoefflin has greatly promoted the further development of the diagnosis from the blood picture. It has been determined that the neutrophils with segmented nuclei and the lymphocytes are biologically complementary. The sum of these two cell groups was utilized by Hoefflin for a geometric formula. After explaining this formula, the author says that he used it on the material of his clinic during the last two years and was able to corroborate the observations Hoefflin made on tuberculous cattle. The method makes it possible to determine (1) that a person never has had biologic contact with tubercle bacilli, (2) that a person is sensitized to tuberculin after the tuberculous foci have disappeared, (3) that a person has a passive tuberculosis and (4) that a person has active tuberculous foci, no matter whether the tuberculin reaction is negative or positive. The formula is also helpful in determining the prognosis and in estimating the efficacy of therapeutic procedures.

Methods of Fever Therapy. K. Nowotny.—p. 295.

Athletic Heart in Roentgenogram.—Erdélyi studied the changes in size and shape of the heart in students who had undergone intensive physical training. He agrees with the majority of investigators, who consider the "athletic heart" a physiologic variant that develops in case of increased activity. He found that the hearts the size of which had temporarily or permanently increased as the result of intensive training in

sports show great differences in shape. These differences are dependent on a number of factors, such as the shape of the thorax, the position of the heart and the changes in the tonus of the cardiac muscle. For instance, a heart that has a median position in a rather narrow and long thorax becomes more spherical in the course of enlargement. In a wide short thorax, however, the hypertrophy is more in the transverse direction and results in an aortic form. Between these two there are of course numerous intermediate forms. The author further explains the relationship between changes in the tonus of the cardiac muscle and the configuration, pointing out that in case of hypotonia the heart often appears pointed, whereas otherwise it is well rounded. He reaches the conclusion that there is no change in size or form of the heart that is characteristic for "athletes' heart" and that the roentgenogram alone cannot serve as basis for the diagnosis of "athletes' heart."

*Unapparent Chronic Pancreatitis. J. W. Grott.—p. 296.

Physiologic Irregularities of Pulse and Respiration. W. Tomaszewski.—p. 300.

Unapparent Chronic Pancreatitis.—Grott says that he has collected 100 cases of unapparent chronic pancreatitis in about two years, not including the cases which he could not verify with the following four points: possibility of diseased pancreas with complication of other organs, careful palpation of the region of the pancreas, search for sugar in the urine two hours after consumption of 50 Gm. of dextrose, and determination of the diastase of fresh urine. Among the 100 cases diagnosed as unapparent chronic pancreatitis there were forty male and sixty female patients, ranging in age from 20 to 70 years. There were liver disease complications in 56 per cent, general debility in 46 per cent, rapid loss of weight in 31 per cent, thirst in 16 per cent, pain in the side in 15 per cent and various other symptoms with insignificant percentage, such as itching in different parts of the body or the genital organs, ulcer of the duodenum and salivation. The treatment of chronic pancreatitis is often long drawn out: the first step is to remove the cause of the pancreatic disease and of that of the other organs. The most important item in the treatment is insulin, once or twice a day, each dose not to exceed 10 units.

Choice of Incision or of Tonsillectomy in Peritonsillar Abscess. T. I. Gordyshevskiy.—p. 352.

Tuberculous Peritonitis.—According to Shwartz, there were admitted from 1925 to 1934 eighteen cases of tuberculous peritonitis to the pediatric section of the Tuberculosis Institute of Leningrad. Among 9,078 cases in which treatment was administered for various surgical conditions at the Raufhus Children's Hospital in the course of seven years there were only seventeen cases of tuberculous peritonitis. The author is skeptical about the enterogenous origin of tuberculous peritonitis. He believes that in the great majority of the cases the primary focus is in the lungs. Tuberculous peritonitis is always secondary to tuberculosis of some other organ or tissue. It is seen most frequently as a concomitant lesion of the secondary stage of pulmonary tuberculosis, resulting from a lymphogenous or hematogenous dissemination from the primary focus. The most frequent sources in order of their importance are the lung and the peribronchial and mesenteric lymph node tuberculosis. In children the principal part of the tuberculous infection is represented by lung tuberculosis. The onset of tuberculous peritonitis in children is not infrequently stormy, with acute abdominal pain and high fever. Such cases are not infrequently confused with acute appendicitis, abdominal typhus and diplococcus peritonitis in girls. The author attaches much

importance to the study of the peritoneal fluid obtained by paracentesis in making a differential diagnosis. High specific gravity, high albumin content and the presence of lymphocytes differentiate an exudate from a transudate. The Gohn-Löwenstein method of culturing the peritoneal fluid on the newer mediums, such as the Pettrignani milk-egg medium, yields a much higher number of positive results in finding Koch's bacilli than the older methods. General hygienic-dietetic treatment occupies the most important position in the treatment of tuberculous peritonitis. Operation is indicated in exudative forms when the conservative measures fail. The results are frequently quite favorable. It is, however, advisable to follow the laparotomy by a general treatment preferably of the climatic-sanatorium type. One should abstain from operating on nurslings, as the results are invariably bad. In adhesive and ulcerative-casating types, the operation is indicated only when signs of increasing intestinal obstruction, of an acute peritonitis due to perforation of the intestine, are present, when the diagnosis is not clear and when cancer is suspected. The author applied the pneumoperitoneum method of therapy in several cases without, however, noticing any favorable results. Tuberculin treatment was not effective. Heliotherapy and other methods of irradiation, such as the quartz lamp, constitute a valuable adjunct and are indicated in cases in which the general state of the patient is fair and the pulmonary lesion is not far advanced.

Nederlandsch Tijdschrift voor Geneeskunde, Haarlem

*Pseudo-Atrophy of Optic Nerve in Young Infants. K. T. A. Halbertsma.—p. 1230.

*Trigger Finger in Young Children. R. J. Harrenstein.—p. 1237.

Habitual Abortion: Case. J. P. Asjes.—p. 1242.

Aseptic Necrosis of Head of Humerus. P. M. E. E. Nijst.—p. 1243.

Pseudo-Atrophy of Optic Nerve in Young Infants.—Halbertsma reports the clinical history of a girl infant, 8 weeks old, who was brought to him by the parents with the complaint that the eyes had a peculiar staring expression which had made them fear that the child might be blind. The ophthalmologic examination revealed an abnormal behavior of the pupils and a peculiar coloration of the optic papillae. On the basis of another examination that was made three weeks later, the disorder was diagnosed as pseudo-atrophy of the optic papillae probably resulting from retarded myelinization of the pupillomotor fibers of the optic nerve. Several successive examinations disclosed a gradual improvement in that the pupillary reactions became more normal and the peculiar coloration of the papillae began to disappear. The author points out that this case corresponds to the description of pseudo-atrophy of the optic nerve in the new-born, which was given by Beauvieux in 1926. He also cites the signs which, according to Beauvieux, differentiate pseudo-atrophy of the optic nerve from the true congenital atrophy of the optic nerve.

Trigger Finger in Young Children.—Harrenstein points out that the so-called resilient, springing or trigger finger is characterized by a sudden arrest of the flexor and extensor movements of the finger. Palpation of the finger occasionally reveals a small swelling in the tendon at the metacarpophalangeal joint. The cause of the thickening of the tendon is unknown. The histologic examination of tissue specimens that were removed during operations revealed various changes. The treatment consists in rest and fixation of the finger on a splint or in forced stretching exercises with or without massage, warm baths and heat treatment. In some cases these measures are effective, but in others surgical treatment becomes necessary. Opening the narrow tendon sheath and removal of the thickening counteracts the difficulty. Thus the prognosis is comparatively favorable. The author further directs attention to the fact that the so-called trigger finger is often observed in young children. In these it is usually the thumb that is involved, often on both sides, whereas in adults the middle or ring fingers are most frequently affected. The author observed the disorder in twelve children, four girls and eight boys. The parents usually observed the defect when the children were between 1 and 2½ years old and without there

having been an injury. Conservative treatment was always tried first. After first stretching the thumb, it was fixed on a metal splint. When this rest treatment gave no improvement, the parents were told to stretch the thumb several times each day. Some of the cases were cured by these conservative measures, but in four cases surgical treatment had to be resorted to. In two cases a cartilaginous thickening of the tendon could be demonstrated as the cause of the disorder.

Ugeskrift for Læger, Copenhagen

99: 319-354 (March 25) 1937

*Acro-dynia (Pink Disease). P. Plum.—p. 319.

Id.: Case. C. Friderichsen.—p. 325.

*Fibrous Mediastinopericarditis (Fibrous Pericarditis) with Especial Regard to Surgical Treatment. D. Bøggild.—p. 328.

Acro-dynia.—Plum states that more than 2,000 cases of acro-dynia are known. The disease occurs almost exclusively in children up to the age of 14. The patients are usually from families in good circumstances. At the onset the child sits quietly or lies with his head in his pillow, is irritable, lacks appetite, has itching fingers and toes, and is thirsty, sleepless at night and dull by day. As a rule the noticeable pink color of the hands and feet appears about the fourth week. Occasionally an eruption may precede, with development of large white blisters, which break and lead to peeling. Other symptoms include pronounced perspiration, salivation and tear flow, falling hair, and possibly necrosis of the gingiva and finger tips. The temperature is normal, the pulse is greatly accelerated, the blood pressure may be increased. In the less typical cases, differential diagnosis with regard to simple anorexia and tuberculosis may be difficult. The picture in arsenic poisoning and ustilaginism resembles that in acro-dynia. Acro-dynia differs from pellagra in the absence of lines of demarcation, digestive symptoms, diet deficiency and history of pellagra in the family, and in the uniform age of the patients. The Woods found that in sixty-two cases the average length of time before improvement was twelve weeks. Angina, stomatitis, bronchitis, pneumonia, pyelitis and gastro-enteritis are complications. A mortality of from 5 to 10 per cent has been noted. Pneumonia is often the cause of death, but in some cases death is due to the disease itself. The course of the disorder is not influenced by diet, vitamin treatment, light, physical procedures or medicaments. The characteristic pathologic changes apparently consist of extensive but slight degenerative processes and slight inflammatory changes in the entire autonomic and somatic nervous system, except the cerebral cortex. A common specific etiology has not been determined. The picture of acro-dynia, erythredema, trophodermatoneurosis or pink disease presents such uniform symptoms and so uniform a course that the disease is justifiably regarded as a well defined entity.

Fibrous Mediastinopericarditis and Surgical Treatment.—In both cases reported there was an exudative tuberculous pericarditis. In the second case the possibility of empyema of the pericardium led to exploratory pericardiectomy, which resulted in the bacteriologic diagnosis of bovine tuberculosis. Bøggild says that fibrous mediastinopericarditis occurs chiefly toward the end of childhood and in early adult life but may occur at any age except early and late. About one third of the cases are due to tuberculosis, about one third to rheumatic infection and the remainder to other known or to unknown causes. An exudate in the pericardium causes distention of the posterior part of the pericardium, resulting in compression posteriorly of the left lung. Stethoscopic signs of this were seen in the two cases. Heart embarrassment due to the exudate may cause liver stasis and ascites. Ascites is hastened after the acute phase and the fibrous changes, with atrophy, produce a mechanical obstruction. Both cases belonged to the concretio type. Cardiolytic, according to Schmiedeknecht, was done in the first case and Brauer's operation in the second. The author states that the operative treatment was undoubtedly life saving. The prognosis depends largely on the causative infection. The best results are attained in slowly developed cases. Intrapericardial pericardiolytic with pericardial resection is the procedure of choice. Operation should be performed before the heart musculature is too much affected.

THE ADVANCEMENT OF MEDICAL EDUCATION

PRESIDENT'S ADDRESS

J. H. J. UPHAM, M.D.
COLUMBUS, OHIO

As I look back on forty years of medical practice I realize that I have lived in a period of medical progress greater and more rapid than any that has ever previously occurred in the world's history. Johns Hopkins Hospital, where for two years I was assistant resident, had opened its doors just five years before I came there. At that time it was considered the last word in hospital construction. Under the leadership of that remarkable quartet composed of Kelly, Halstead, Welch and Osler it stood at the peak of medical science and medical practice in our country. Howard Kelly, with his marvelous dexterity and operative skill, inventive genius, exploring the bladder and catheterizing the ureters, the only man in the country able to do so at that time, was easily the leading gynecologist of the United States if not the world. Thomas Halstead with his great contributions to surgery, surgical pathology and surgical technic was an outstanding leader in his field. William Welch, of beloved memory, had already made many great contributions to the knowledge of pathology. Of even greater worth, he brought pathology from the laboratory and necropsy room to the bedside and made it an integral part of clinical teaching and clinical practice. And there William Osler, often called the greatest of modern physicians, gave some fifteen of the most productive years of his life. Great as a medical scientist and clinician, he seemed greatest as a teacher and a source of inspiration to other physicians. Like the immortal Johann Müller, he inspired all assistants and students with whom he came in contact.

As I look back I try to visualize the modern intern, and indeed the modern hospital staff as well, were they compelled to work under the conditions existing then in the leading medical institutions in the country. I believe they would be quite at a loss or even helpless. In addition to the history taking in a ward of twenty-eight beds and assisting in the operating room, the assistant resident was required to do all the clinical laboratory work for his ward. This sounds much more than it implies today, however. The laboratory contained for routine work merely some test tubes, Fehling's solution, nitric acid and the stains for the tubercle bacillus. Occasionally one used the bromine test for urea and the fermentation test for urinary sugar. Occasionally also we used the hemoglobinometer and counted the red and white blood cells, but our results were often

haphazard. Thayer had just been doing his work in the fertile malarial districts around Baltimore, so that we looked for and not infrequently found the elusive plasmodium. Ehrlich had just announced his early experiments with blood stains, and with his long copper drying bar and triacid stain we often produced results fearful to behold. We knew the more common pathogenic bacteria and tested for them on our own laboratory made mediums.

The laboratory was without technicians, blood chemistry, agglutination tests, blood typing, determination of liver or kidney function, and Wassermann and tolerance tests. Above all there were no x-rays. One winter day I read on the bulletin board the announcement that a distinguished American professor of dentistry would give a lecture that afternoon in the hospital amphitheater. After an interesting and informal talk, he passed around a half-dozen glass photographic and crude plates, which had been given him a month or so previously by his friend one Professor Roentgen. These were the first x-ray plates brought to this country. There was no seer among us to prophesy what this seeming scientific curiosity was to mean to dentistry and medicine!

In those days there was no knowledge of insect-borne diseases, food deficiency diseases—except perhaps scurvy—vitamins, endocrines, hormones, insulin, virus diseases, the electrocardiogram, allergy, serology, standardized drugs and other innumerable improvements of modern therapy. These are the harvest of the last forty years. The average modern medical student tries to acquire them in four hectic years of forced mental feeding. Some were taught ten, twenty or thirty years ago. Whatever the date of graduation, however, the newly pledged doctor is a perishable article sold under a guaranty that is good only on that date. There is not even an expiration date as on vaccine or serum. In a few months, certainly in a few years, unless he keeps up with the march of progress he lags behind.

The graduate of ten or twenty years ago has had to add to his basic information as much as he acquired in his college course; if not more. Legally when he receives his license to practice he is a finished product; actually he has just made a fair start in his educational life. His future progress under present conditions is a matter entirely of his desire for self improvement and personal initiative, stimulated by ambition or financial self interest. That so many of those in practice do keep well abreast of the march of progress is a gratifying tribute to the spirit of our profession. The fact that some do not progress is a matter of great concern and a subject for serious consideration.

POSTGRADUATE EDUCATION

There are four main procedures by which postgraduate self education is attainable: First by personal experience and clinical observation—the method of

President's address before the American Medical Association at the Eighty-Eighth Annual Session, Atlantic City, N. J., June 8, 1937.

Hippocrates, Galen and Sydenham. This should be the habit of every physician as an underlying part of his program.

Second, training in postgraduate colleges. This is mainly directed toward the development of education in the various specialties and, while excellent, affects only a relatively small percentage of physicians.

Third, through medical publications. We have more and better medical publications today than are available in any other country in the world. For this the American Medical Association is largely responsible by setting up standards in every field and thus aiding the advancement of general and specialized knowledge. The existence of so many of our publications is definitely a response to the widespread demand for the latest medical information.

Fourth, through medical society meetings. For centuries it has been the habit of physicians to assemble from time to time to discuss mutual problems, relate experiences of medical practice and announce new discoveries. In the early days of this country this practice was followed in the better settled areas. Many medical societies have already celebrated the one hundredth anniversary of continuous existence. Ninety years ago the American Medical Association was founded to organize the medical profession on a national basis, correlate the activities of the constituent societies, and present at its annual meeting the latest developments of medical progress.

In the county society there is the opportunity for all members to report cases and present papers on medical subjects. Guest speakers add to the value and interest of the programs and increase their educational value. A by-product of this plan of organization has been the great improvement in the mutual relations of the local members. The regular meetings of county medical societies have led to better acquaintance and mutual respect between the members; friendliness and cooperation have replaced enmity and discord, to the great gain in the quality of local medical practice.

The annual meetings of the state medical associations represent a higher grade of postgraduate instruction. The excellence of the scientific programs and the high quality of the discussions at these meetings indicate how they are meeting their responsibilities. In forty states last year the average attendance was 38 per cent of the membership.

The highest grade in our organization educational scheme is the annual meeting of the American Medical Association with its splendid programs of scientific papers and technical discussions covering every department of medicine. Annually from 5 to 8 per cent of our entire membership attends these meetings. And yet the medical meetings I have mentioned are merely the beginning. In every large city and in many states there are sectional and special societies holding frequent meetings. In the latest American Medical Directory 140 national and sectional societies are listed, and to these must be added the almost countless hospital staff meetings throughout the country.

The Council on Medical Education and Hospitals lists 6,189 approved hospitals, each of which is supposed to hold a monthly staff meeting for ten months of the year. It is staggering to contemplate the grand total of all these meetings. Here certainly is definite proof of the urge for self improvement of the members of our profession. The multiplicity of meetings, however, has become a burden. Conditions are chaotic and the problem merits serious consideration.

Several years ago, programs of postgraduate study were organized for the use of county societies with weekly outlines published in *THE JOURNAL*. Some good resulted but in general this scheme failed because of the lack of leadership and trained individuals in the various areas to oversee and carry out the courses. In some states in the last few years, efforts have been made to carry on this sort of instruction through the cooperation of medical colleges and state associations. Systematic courses in the newer developments of medical science with their application to general practice have been carried to strategic points in their states by traveling groups of trained clinicians and medical teachers. In this way large numbers are reached with a minimum of effort and loss of time.

Our best argument against the establishment of foreign schemes of socialized medicine is continued maintenance of the high plane of medical practice in this country. A large percentage of lagging members constitutes a beam in our professional eye.

There is already a trend toward compulsory evidence of postgraduate improvement. At first there was merely moral suasion in the requiring of evidence of fitness by passing examinations for admission to membership in the various national special societies. A second step has been taken in the recognition of such membership in the classification of specialists in the American Medical Directory. In several states there are laws requiring annual registration of physicians. While, apparently, not utilized to any extent as yet, the authority is seemingly present to weed out undesirables such as narcotic addicts and those guilty of criminal offenses. There is the possibility that the next step might be a requirement for renewal of licensure through evidence of familiarity with the developments in medicine by five or ten year periodic examinations.

THE COUNCIL ON MEDICAL EDUCATION

The Council on Medical Education and Hospitals in the last thirty years has done a monumental service to medical education and the public. As the chairman, Dr. Wilbur, said in his address before the Congress on Medical Education and Licensure last February, "The record of thirty years shows that the Council on Medical Education, exercising an effective and impartial supervision over the training of physicians, has brought about an advance unparalleled in the history of education." In its first inspection and grading of medical colleges it did much to remedy a situation that was a reproach and indeed a scandal to the name of medical education. In its second inspection of the last two years it has carried on that work in logical sequence and further advanced the standards of our colleges so that they compare favorably with any in the world.

In its inspection of hospitals and the institution of standards for intern training it has initiated a definite program for providing the public with thoroughly qualified practitioners. From that time on, however, the practitioner is left largely to his own devices and his personal initiative as to his future development.

This council has no legal status or statutory power of enforcement, but by support of medical opinion and the publicity given its reports in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* it was able to reduce the number of 186 medical colleges, some good, many bad and the remainder indifferent, to seventy-five of acceptable quality. Much the same result has been apparent in the eager efforts of hospitals to meet the standards of an "approved" hospital. Such a response is a tribute to its wise judgment and a recognition of its

authority. Lest, therefore, there arise a demand from without our ranks for an "approved practitioner," the American Medical Association should of its own initiative study the present situation and take measures to forestall such an eventuality.

MEDICAL MEETINGS

It is evident from the number of medical society meetings at present being held, the excellent attendance reported generally and the great number of medical publications supported by our members, that the majority of the medical profession of this country is alive to the need of continued education and is seeking voluntarily to take advantage of the opportunities presented. It must be admitted, however, that a small percentage does not attend medical meetings and does little to keep up with medical progress. The good name of our profession suffers from such an attitude of even a relatively small group, and here lies a challenge to our organization.

Isolation and the lack of accessibility of meeting places are often valid excuses for much of this non-attendance. To meet this, I would urge a comprehensive study of the traveling postgraduate courses already in operation in some states with the idea of a more general and systematized development of such a plan. From an extensive acquaintanceship with practitioners I am confident that, if such educational opportunities were thus made available at accessible points, the response would be prompt and encouraging. In such efforts, however, there should be careful selection of a well balanced and well presented program, considerations too often lost sight of unfortunately in many of our meetings. Highly scientific or technical papers are of great value but should be restricted to audiences that can comprehend them, or couched in language understandable to the average listener, and with an emphasis on the application to medical practice. In all meetings, whether of the suggested traveling postgraduate or the regular county, state or national societies, more definite consideration should be given to the majority of the attending audience in arranging programs and in the method of presentation to the end that the programs may be more attractive and that the greatest good may be gained by the greatest number.

In this the American Medical Association may assume a scheme of leadership and guidance that will demonstrate that it has a definite plan of medical education not only for the undergraduate and the intern but also for all its members throughout their entire period of medical life expectancy. The result will be a better profession, a more united front with better service to the public and a greater progress of medical science. With such a scheme of activity in these days of medical and economic unrest, our medical conscience may be reassured and all may take hope that American medicine will show to the world the highest standards of medical science and medical practice.

And so may be fulfilled that whimsical dream of William Osler as recounted in his "Vienna Revisited" in *THE JOURNAL* of May 9, 1908. He pictured a fancied interview with Minerva Medica; how she fled because of changing conditions from Greece to Italy, to France, Holland and Germany, and, when he invited her to cross the Atlantic and set up here her temple, she replied: "Give me the temples, give me the priests, give me the true worship, the old Hippocratic service of the art and of the science of ministering to man, and I will come. By the eternal laws under which we gods live I would

have to come. I did not wish to leave Paris, where I was so happy and where I was served so faithfully by Bichat, by Laënnec and by Louis"—and tears filled her eyes and her voice trembled with emotion—"but where the worshippers are the most devoted, not, mark you, where they are most numerous; where the clouds of incense rise highest, there must my chief temple be, and to it from all quarters will the faithful flock. As it was in Greece, in Alexandria, in Rome, in northern Italy, in France, so it is now [or was] in Germany, and so it may be in the new world I long to see."

PROFESSIONAL FREEDOM AND SOCIAL RESPONSIBILITY

CHARLES GORDON HEYD, M.D.

NEW YORK

In every age and in every cultural order, the doctor has existed and maintained himself in spite of war, catastrophes and revolution. He lived and practiced his art during the decline and fall or even the complete annihilation of previously existing states of civilization. From remote times the doctor has enjoyed complete professional freedom and has thereby assumed great social responsibility.

Through the centuries, fundamental discoveries made by practicing physicians have changed the whole current of life. Vaccination against smallpox, the discovery of the bacterial causes of disease, the development of the stethoscope, the cystoscope and other instruments of precision and the x-rays, the discovery of the specific effects of certain medicaments, such as vitamin therapy in deficiency diseases, liver therapy in anemias, and insulin in diabetes, have all given to many human beings increased years of greater usefulness. These discoveries were made by physicians without any monetary remuneration or any expectation of personal advantage. These significant contributions have made possible a lessening of disease, increased longevity and incalculable relief from suffering. Humanity has benefited probably more from the contributions of physicians than it has through the mastery of man's environment by the discoveries in the physical sciences. Humanity has benefited in a social sense more by the work of physicians than it has by inventions in government.

Mass methods in medical practice are definitely approaching an end. Certain diseases, such as typhoid, diphtheria, syphilis and malaria, lend themselves to mass control by the sanitary engineer and technician. But the practitioner of medicine in the future will be employed largely in a more personal relationship to disease. We are slowly developing a society in which old age with its degenerative conditions will represent a constantly increasing percentage of disease. The United States by 1960 may have a stationary population, and the leading causes of death and physical disability will be in the degenerative group of disease. One out of four or five of the population will be over 60 years of age, and heart disease, cancer, nephritis, pneumonia, accidents and apoplexy will move up as the chief causes of death. Medical practice will require a more personal service, a more extensive control, and, I believe, will require more physicians to take care of them.

Address of the retiring President delivered before the American Medical Association at the Eighty-Eighth Annual Session, Atlantic City, N. J., June 8, 1937. Dr. Charles Gordon Heyd succeeded Dr. James Tate Mason, who died June 20, 1936.

Largely by reason of our individualism and the fact that we explored and developed a virgin continent with the spirit of the pioneer, the United States has had a better health record than obtains anywhere else in the world. The final analysis of the social intelligence of a people will rest on their health program. Wherever we survey a typical death-producing disease and its effect on the community, we find that the record of the United States is superior to that in countries with either a socialized medical system or compulsory health insurance. The final appraisal of our national well being will rest on mortality statistics.

There are certain portions of the United States where it is impossible under present conditions to provide any fair degree of medical service. Until the levels of these backward areas are elevated culturally, physically and intellectually by more education, by proper housing, by adequate nourishment, by better protection against climatic and endemic disease, it will be futile to expect a medical service comparable to that in the most intelligent, advanced and socially minded states of the Union. In certain areas less than 10 cents per capita is spent annually on public health, as compared to \$2.85 per capita annually in our more advanced states. A single example will suffice: Until the diet of certain groups of people has been brought up to a vitamin maintenance level by increasing their earning capacity and by education, it would be foolish to talk about adequate medical and dental services.

What a fallacy! To assume that all the people at all times, under all conditions, can receive what is so glibly spoken of as "adequate medical service" or even as the "best of medical care." It is impossible to make people of ordinary average intelligence look after themselves. It is notorious that there is more delayed medical attention among employees and nonprofessional staffs of hospitals than those outside the hospital field. What a flight from reality to suppose that we can make any effective inroads on the recalcitrance of human nature when we have 16,000 chiropractors, 7,600 osteopaths, 2,500 naturopaths and 10,000 Christian science healers taking \$125,000,000 a year from the American people for unscientific or one track systems of healing.

America is confronted with the following social conditions: increase in population, a tremendous increase in the number of highly educated citizens, an increasing mechanization of life with urban condensation, a shift from the agrarian to the industrial form of life, gigantism in industry and hospitalization, a change in the concept of government and finally the political power of masses.

Increased morbidity, with more hospital days, is the inevitable consequence of assuming a compulsory health insurance scheme. It is impossible to set up any state system of medicine or compulsory health insurance without creating a class of bureaucrats whose self interest maintains them in office. These possess the poisonous virus of all bureaucracies—an insatiable desire for increased power. The maintenance of this bureaucratic personnel is a permanent obligation of society in good times and in bad times. There follows from above downward a diminishing spiral of effectiveness: (1) the bureaucracy that administers the scheme, (2) the patient who receives the services and (3) the doctors who render the service. More and more of the tax dollar goes to the upper segment and less to the lower. The constantly increasing cost of administration is offset by less and less service to the patients, decreas-

ing remuneration to the physicians and a rapid continuing deterioration in the quality of medical services.

Modern medicine may be divided into two major domains: one is the scientific phase represented by the utilization of all discoveries that can be applied to the alleviation of human suffering or the banishment of disease. These discoveries in medical science have been made throughout time but reached their most startling importance in the last fifty years, when man obtained the mastery over his environment by discoveries in the field of physical science.

The second aspect of medical practice is that scientific data must be correlated, applied and distributed. This is the art of practice and in it there is a surprising difference in abilities and in technic. It is said that Jenner was not a noteworthy physician, yet he gave humanity an epochal discovery. Robert Koch was an indifferent therapist but became a scientist with the discovery of the bacterial origin of disease.

There is today a large bulk of scientific medical measures that must wait until the level of intelligence of the people is prepared to accept them. As indicating the tremendous gap between scientific accomplishment and its clinical application, one may recall that there were "not half a dozen clinical thermometers employed in the largest Union army throughout the Civil War"; yet this was 250 years after the discovery of a means of recording changes in temperature.

In 1905 Schaudin discovered *Spirochaeta pallida* and in 1906 Wassermann introduced the serum diagnosis of syphilis; in 1910 Ehrlich and Hata discovered arsphenamine; yet only in 1937 has the word "syphilis" been permitted on the radio. The eradication of syphilis has been possible during the past twenty-five years.

The quality of medical services depends on medical education. Medicine has evolved in the United States in the last 150 years from the circuit rider with saddle bag, through the preceptor stage, to the medical school with its premedical requirements. Conspicuous in the advancement of medical standards has been the Council on Medical Education and Hospitals of the American Medical Association, which began in 1905. It has led in the development of a public sentiment for the eradication of the proprietary and incompetent medical schools and an increase in premedical education. It has inspected medical schools and hospitals and approved the latter for interns and residence appointments. It has created a mechanism for approving boards to certify to the competence of specialists.

In response to the needs of the time, the American Medical Association is to make a survey and coordinate all the graduate and postgraduate facilities of the United States so that these in turn may be the means of increasing the qualifications of physicians for more effective and better medical service to the community.

The quality of all social services rests primarily on character, and the relationship of the doctor to the community is based on the ethics of the medical profession. Critics of medical organization sardonically suggest that the Code of Ethics is to protect the so-called vested rights of the physician in sickness. Nothing is more erroneous. The Code of Ethics is for the protection and benefit of the public.

Medicine has the properties of a living organism. It is dynamic and evolves with the spirit of the times. Every society throughout history has formulated an ideal of medical service. From about 1800, medicine changed from its disparate existence and became a responsible mechanism of society. One may hopefully

anticipate that in this country there shall emerge a progressively advancing type of medical education and medical services which may be called the American system. The science of medicine and the art of medical practice must retain its freedom and professional liberty. The medical profession "does not rely on endowment but on its own exertions directed to meeting human wants. There is no great profession which has so little to say to the public purse and which so moderately and modestly dips its hand into that purse. It is not only in the interest of the public, but of the profession itself, that it is eminently self supporting. Rely upon it: the principle of self support does much to maintain its honor and independence, and to enable it to pursue its stately march in the times that have come and in the times that are coming, to form its own convictions, to act upon its own principles without fear or favor, for the general benefit of mankind."

THE INCIDENCE OF TRICHOMONADS IN THE VAGINA, MOUTH AND RECTUM

EVIDENCE THAT VAGINAL TRICHOMONADS DO NOT
ORIGINATE IN THE MOUTH OR INTESTINE

P. BROOKE BLAND, M.D.

AND

A. E. RAKOFF, A.B.

PHILADELPHIA

Until it has been definitely proved whether or not trichomonads from one source may survive and multiply in other organs, the possibility of auto-infestation remains an important factor in the prevention and treatment of trichomonad infestations, especially the common clinical entity trichomonas vaginitis. The probability of autotransmission depends, however, on the incidence of the organisms in the suspected foci, while the percentage of multiple infestations may be considered as an indication of the extent to which it has occurred. Although the incidence of *Trichomonas* has been reported by a number of workers, we are not aware of studies of the incidence of trichomonads from these three sources in any one group of individuals.

In the present investigation such a study was undertaken among a group of 200 women. All the available laboratory methods of diagnosis, including examination of the fresh specimen by wet smear and stained preparations as well as culture methods, were employed and their relative efficacy noted. Cultural differences indicating pertinent physiologic distinctions among the trichomonads from human hosts are also described.

MATERIALS AND METHODS

One hundred consecutive white and an equal number of colored women attending the antepartum and postpartum clinics of the department of obstetrics at Jefferson Medical College Hospital were studied for the presence of vaginal, intestinal and buccal trichomonads. The technic employed for the collection of material for examination was as follows:

1. *Vaginal Specimens*.—With the patient in the dorsal position the vaginal tract was exposed by means

of a bivalve speculum. A copious sample of the vaginal secretion was collected on a sterile cotton swab and dropped into a test tube containing 2 cc. of sterile Ringer's solution. Only those patients were included in this study who had received no douches or other local vaginal treatment for at least a month prior to the present examination.

2. *Intestinal Specimens*.—Wherever possible a fresh specimen of feces was collected by digital manipulation. The gloved forefinger, lubricated with a small amount of sterile petrolatum, was introduced well into the rectum and with it a small mass of feces was separated from the formed stool and gently worked past the external sphincter to be collected in a test tube containing 5 cc. of Ringer's solution. In thirty-eight instances in which a satisfactory specimen could not be obtained in this manner it was found necessary at a subsequent visit to have the patient defecate in a special cardboard container provided for the purpose.

3. *Buccal Specimens*.—A sterile cotton swab was thoroughly rubbed over the inner and outer surfaces of the entire upper and lower gum lines and into any cavities that were present. This swab was then dropped into a tube containing 2 cc. of sterile Ringer's solution.

All three specimens were taken to the laboratory immediately after their collection, and examinations by the following methods were conducted without delay:

A. *Examination of Fresh Material*: The specimens were well emulsified in the Ringer's solution and a copious sample was carried onto a glass slip by means of a cotton applicator. The slides were thoroughly examined under the low and high dry objectives for the presence of trichomonads.

B. *Examination of Fixed and Stained Preparations*: Several smears of each specimen were prepared on cover slips, fixed for fifteen minutes in warmed Schaudinn's fluid with 10 per cent acetic acid and stained by the iron hematoxylin method. At least two slides from each specimen were examined for a total of ten minutes under the oil immersion objective for the presence of trichomonads.

C. *Examination by Culture Methods*: Although a number of mediums have been recommended for the cultivation of the various trichomonads, it was decided for the purposes of this study to employ a medium that has given general satisfaction for the growth of trichomonads from all three sources studied; namely, 0.4 per cent Loeffler's dehydrated blood serum in modified Ringer's solution (sodium chloride 6 Gm., potassium chloride 0.1 Gm., sodium bicarbonate 0.1 Gm., calcium chloride 0.1 Gm., distilled water 1,000 cc.). Two cultures from each specimen were prepared, each containing 0.5 cc. of the emulsified material in 10 cc. of culture medium. One tube was incubated at room temperature and another at 37.5 C. Cultures were examined daily for at least four consecutive days. When positive cultures persisted only at incubator temperature, their ultimate cultivability at room temperature was determined by repeated subcultures from positive incubator tubes.

RESULTS

The total incidence of trichomonads of vaginal, buccal and intestinal origin (*Trichomonas vaginalis*, *T. buccalis* and *T. hominis*, respectively) is given in table 1, as well as the incidence obtained by each of the three methods of study employed; namely, fresh wet smear examination, stained smears and culture methods.

From the Department of Obstetrics, Jefferson Medical College Hospital.
Prof. David H. Wenrich of the Department of Protozoology at the University of Pennsylvania showed constant interest and gave numerous helpful suggestions during the course of this study.

It will be noted that the total incidence of the vaginal trichomonads (23.5 per cent) is approximately one and a half times as great as that of *Trichomonas buccalis* (16.5 per cent) but almost sixteen times as great as that for the intestinal form (1.5 per cent). The incidence of *Trichomonas vaginalis* in colored patients in this study was almost twice as great as that for the

TABLE 1.—Incidence of Vaginal, Buccal and Intestinal Trichomonads

Source	Positive in Wet Smears	Positive in Stained Smears	Positive in Culture	Total Incidence		
				Entire Group	White Women	Colored Women
Vagina	47, or 23.5%	31, or 15.5%	32, or 16.0%	47, or 23.5%	17.0%	30.0%
Mouth	3, or 1.5%	None	33, or 16.5%	33, or 16.5%	13.0%	18.0%
Rectum	2, or 1.0%	1, or 0.5%	3, or 1.5%	3, or 1.5%	1.0%	2.0%

TABLE 2.—Repeated Studies of Three Patients with Intestinal Trichomonads

Patient	Period of Study, Weeks	Specimens Examined	Positive in Wet Smear	Positive in Stained Smears	Positive in Culture

2	18	9	9	4	9
3	8	4	2	1	4

white patients, while the incidence of the buccal trichomonads was only slightly higher in the colored group.

The total incidence, as determined by a combination of the three forms of laboratory study, did not exceed the incidence as determined by some one of the three methods alone; however, the most efficient method was not the same for the material from the three different sources. Thus, in the case of the vaginal trichomonads the number of positive results determined by the examination of fresh wet smear preparations equaled the number determined by the combination of methods, whereas in the specimens from the mouth and rectum the total number of positive results was determined by the culture methods alone.

The small percentage (1.5) of positive buccal wet smears is indicative of the small numbers of organisms that are generally found in the infested mouth and is further reflected by the fact that none were found on the prepared slides. The easy cultivability of *Trichomonas buccalis*, however, indicates that infestation is present in more than ten times the number of cases in which wet smear preparations alone would lead one to suspect their presence (table 1). On the other hand, the concentration of trichomonads in the infested vagina is usually sufficiently great to make the diagnosis by the wet smear method the most efficient, especially in view of their difficult cultivability. The active motility of trichomonads in fresh preparations is a further factor in accounting for the superiority of the fresh smear method over stained preparations, together with the fact that trichomonads are especially difficult to fix and stain properly.

In the examination of the fecal specimens for trichomonads the culture method gave the highest percentage of positives (three, or 1.5 per cent). In the two instances in which the organisms were seen in the wet smears they were present in large numbers in one instance but were very sparse in the other. Although only three cases of intestinal trichomoniasis occurred,

repeated examinations indicated not only that the culture method was the most reliable for diagnosis but that the trichomonads persisted throughout the periods of observation, ranging from eight to forty-two weeks (table 2). Permanent slides proved comparatively poor for the diagnosis of intestinal trichomonads, whereas Wenrich, Stabler and Arnett¹ found them to be most efficient for the diagnosis of intestinal amebae.

A study of the multiple incidence of the trichomonads from all three sources (table 3) indicates that the degree of correlation is not greater than would be expected from chance distribution alone. Only one woman was positive for trichomonads from all three sources studied. Nine, or 4.5 per cent, of the group were infested with vaginal and buccal trichomonads. Thus, of the forty-seven patients with *Trichomonas vaginalis* nine, or 19.1 per cent, harbored *T. buccalis*, while for the group at large the incidence of the latter form was 16.5 per cent. The patient who harbored all three trichomonads was the only one positive for vaginal and intestinal forms or for buccal and intestinal forms.

The employment of routine culture methods among the present group of 200 women afforded an opportunity for studying the relative cultivability of the three forms of *Trichomonas*.

It is of interest that, although in thirty-two, or 68.1 per cent, of instances of vaginal trichomoniasis the organisms could be cultivated at 37.5 C., none of these strains persisted at room temperature, nor did subsequent subcultures prepared from good cultures become positive when incubated at room temperature (table 4). Although two cultures at room temperature showed a few organisms after twenty-four hours which were probably survivors from the original inoculum, they could hardly be classified as successful cultures. On

TABLE 3.—Multiple Incidence of *Trichomonas* from Vagina, Mouth and Rectum

Positive for trichomonads from all three sources.....	1, or 0.5%
Positive for vaginal and buccal trichomonads	9, or 4.5%
Positive for vaginal and intestinal trichomonads	1, or 0.5%
Positive for buccal and intestinal trichomonads.....	1, or 0.5%

TABLE 4.—Cultivability of Vaginal, Buccal and Intestinal Trichomonads

	<i>T. Vaginalis</i> (47 Strains)	<i>T. Buccalis</i> (33 Strains)	<i>T. Hominis</i> (3 Strains)
Original culture positive at 37.5 C.	32, or 68.1%	33, or 100%	3, or 100%
Original culture positive at room temperature	2, or 4.3%*	10, or 33.3%	2, or 66.7%
Ultimately cultivable at room temperature	None	31, or 93.9%	3, or 100%

* A few organisms survived for from twenty-four to forty-eight hours.

the other hand, of the thirty-three strains of *Trichomonas buccalis* studied all were easily cultivable at incubator temperature; ten strains were recovered from cultures kept at room temperature, while thirty-one were ultimately cultivable at room temperature. All three strains of *Trichomonas hominis* grew well at 37.5 C., two were also positive in the original tubes at room temperature, while the third was later cultivated at room temperature.

COMMENT

Various opinions are still held concerning the specificity of the vaginal, buccal and intestinal trichomonads in spite of the numerous laboratory and clinical investigations of the problem.

Distinct differences in morphologic characteristics among the three forms have been demonstrated by the careful comparative studies of Wenrich,² and more recently by the investigations of Powell.³ It has been suggested by Andrews,⁴ Lynch,⁵ Dobell⁶ and many others that under similar environmental conditions the species may be identical, apparent distinctions being the result of differences in habitat. Experimental animal inoculations have been advanced by Hegner⁷ and by Dobell⁶ in support of this contention, while the experiments of Kessel and Gafford⁸ and of Bonestell⁹ indicate an organ specificity for the trichomonads of human hosts.

On the basis of inoculations into human hosts Karnaky¹⁰ believes that infestation of the vagina may be produced with trichomonads of intestinal and buccal origin and states¹¹ that these "convert into the vaginal form when transplanted into a trichomonal free vagina," although no criteria or discussion of observations are given to substantiate this statement. We¹² have not been able to confirm Karnaky's results with the intestinal and buccal forms, although we have been able to produce a vaginal infestation with *Trichomonas vaginalis* from culture.

From a clinical point of view, *Trichomonas vaginalis* is the most common as well as the most important cause of human infestation by trichomonads, since the leukorrhea and vaginitis with which it is so frequently associated are generally acknowledged to be caused by the flagellate. The opinion has frequently been expressed by clinicians that vaginal infestation has its origin from intestinal or buccal contamination.

This belief has led to the institution of improved hygienic measures, especially with a view to preventing vaginal infestations after initial local treatment. However, the practice of giving drugs by mouth, as suggested by Bradley¹³ and Karnaky,¹⁴ or of adjusting gastric acidity, as reported by Bogess,¹⁵ not only has little scientific justification but, when such drugs as arsenicals are given,¹³ may be actually dangerous to the patient's health, in addition to removing emphasis from rigorous local treatment. At the very least, exam-

ination for intestinal trichomonads should be made before the treatment of a condition which may not exist is undertaken.

It has been demonstrated in the present study in our clinic, where vaginal trichomoniasis is common, intestinal infestation with *Trichomonas* is rare and even when present is not more frequently associated with vaginal infestation than would be expected from chance distribution. The latter fact is of especial interest because it has been demonstrated that, among the patients harboring *Trichomonas hominis*, the organisms may be repeatedly demonstrated in the feces over a considerable period of time, thus affording ample opportunity for vaginal infestation to occur. In a study of a large number of oriental women Matsuda¹⁶ also noted that there was no tendency for the patient to be parasitized with intestinal and vaginal trichomonads at the same time. The incidence of intestinal infestation among the 200 patients in the present study is in general agreement with those noted for other groups in this climate. Craig¹⁷ estimates that in temperate regions from 0.5 to 1 per cent of individuals examined harbor *Trichomonas hominis*. Hegner and Payne,¹⁸ from a review of thirty-five papers by American, English and French investigators including 20,000 cases, estimate the incidence at 3 per cent. Lynch⁵ believes the percentage in warmer climates and in patients with gastro-intestinal disturbances is considerably higher.

Vaginal auto-infestation with buccal trichomonads has received considerably less attention than has infestation with the intestinal form, although this possibility has been emphasized by Lynch.¹⁹ On this assumption the much higher incidence of the buccal trichomonads as demonstrated in this study, as well as by Beatman,²⁰ Hinshaw,²¹ Hogue²² and others, together with the fact that saliva is commonly used in sexual practices, would indicate that this is a considerably more prevalent source of infestation than would be possible from fecal contamination. Further, it has been pointed out by Bland, Wenrich and Goldstein²³ that morphologically *Trichomonas vaginalis* more closely resembles the buccal form.

From the data of the present study auto-infestation from the buccal source was considered improbable for the following reasons: (a) the comparatively low incidence of buccal trichomonads, (b) their scant numbers even in positive cases and (c) the failure to note any considerable increase in incidence in vaginally infested patients.

It has been generally accepted that cysts or other resistant stages of *Trichomonas* do not exist and consequently that intestinal infestation requires the successful ingestion and gastric passage of the motile forms. This mode of intestinal infestation has been demonstrated by animal inoculation by Hegner²⁴ and by

Wenrich and Yanoff.²⁵ If successful transference of *Trichomonas* from one source to another is possible, an incidence of intestinal infestation many times lower than buccal trichomoniasis in the same group of patients, as obtained in this study, remains to be explained.

The investigation of the incidence of the flagellates by cultural methods as well as by the direct examination of the specimen by wet smear and stained preparations has amply demonstrated that the highest percentage of infestation is dependent on the method of diagnosis. However, it has been our experience that the culture method alone will reveal buccal and intestinal trichomonads as frequently as will the combined methods, while wet smear examination alone will determine the total incidence of vaginal infestation.

Although good cultures of all three forms of *Trichomonas* have been obtained in various mediums by a number of workers, few reports on the cultivability at room temperature are available. Das Gupta²⁶ cultivated twenty-three strains of intestinal trichomonads in Reno's medium; he was not able to obtain positive cultures at 22 C. or lower. Kofoid and Swezy,²⁷ on the other hand, cultivated *Pentatrichomonas* from feces in 10 per cent serum in Locke's solution with facility at room temperature. *Trichomonas buccalis* was cultivated by Hogue²² at 26 C. and 30 C. as well as at body temperature. Andrews⁴ found that *Trichomonas vaginalis* did not grow at 28 C.

The cultural differences of the vaginal trichomonads as compared with the other two forms, especially the inability to obtain successful cultures of *Trichomonas vaginalis* at room temperature, indicates physiologic differences among the three forms. Indeed, it may be stated with some degree of certainty that a trichomonad from a human source which can be cultivated and maintained at room temperature is not of vaginal origin.

SUMMARY

1. Our study of the incidence of *Trichomonas* from the vagina, mouth and rectum of 200 women employed wet smears, stained slides and culture methods.

2. Vaginal infestation with *Trichomonas* was common, occurring in 23.5 per cent of the group. Buccal infestation occurred in 16.5 per cent of the patients, while intestinal trichomoniasis was comparatively rare, being present in only 1.5 per cent of the women.

3. It was demonstrated that the wet smear method is the most efficient for the diagnosis of *Trichomonas vaginalis*, while the culture method was much superior for the detection of the intestinal and buccal trichomonads.

4. Women harboring vaginal trichomonads did not show an appreciably higher percentage of buccal or intestinal trichomonads than was noted for the group at large. Only one woman (0.5 per cent) harbored all three organisms.

5. Rectal contamination was regarded as an improbable source of vaginal infestation in view of the rarity of intestinal trichomoniasis among women with *Trichomonas vaginitis*.

6. Of three patients harboring intestinal trichomonads, only one was positive for *Trichomonas*

vaginalis despite the fact that the flagellates could be regularly demonstrated in the feces over long periods of time.

7. Auto-infestation with buccal trichomonads was also considered an unlikely source of vaginal infestation because the dual incidence of these organisms was not more than would be expected from chance distribution.

8. A comparison of the incidence of trichomonads from the bowel and mouth indicates that intestinal infestation probably does not result from ingestion of the buccal forms.

9. Unlike the intestinal and buccal trichomonads, *Trichomonas vaginalis* was not cultivable at room temperature and was considered physiologically different.

DIABETES MELLITUS

REPORT OF A CASE RESISTANT TO INSULIN BUT
RESPONSIVE TO A CHANGE IN THE TYPE
OF CARBOHYDRATE FED

HOWARD H. MASON, M.D.

AND

GRACE E. SLY, B.S.

NEW YORK

Since the introduction of insulin, cases have appeared from time to time that showed most of the symptoms and signs of diabetes mellitus but did not respond to insulin. The physiologic explanation behind most of these conditions is still obscure. For this reason we are reporting the following case, which was insulin resistant but did respond to a change in the type of monosaccharide derived from the food:

H. W., a white boy, aged 25 months, was admitted to Babies Hospital July 11, 1935, for malnutrition and glycosuria. The family history was irrelevant. The patient had had repeated respiratory infections with otitis media and one attack of bronchopneumonia. He was small at birth and gained very slowly in spite of adequate amounts of food and vitamins. The weights were: at birth 4 pounds 14 ounces (2,213 Gm.); at one year 12 pounds (5,443 Gm.); at eighteen months 13½ pounds (6,123 Gm.); at 25 months 15¼ pounds (6,917 Gm.). Sugar was discovered in the urine in October 1934, when he was 18 months old. Until March 1935 an unsuccessful attempt was made to control the glycosuria by regulating the diet. From then until admission, insulin was used in increasing amounts, up to 60 units a day, without controlling the glycosuria.

He was a small infant with thin legs and arms and a protuberant, tense abdomen. He was 40 per cent under weight and considerably under height for his age. There was more than the normal quantity of hair on his trunk and extremities. There was a yellowish pigmentation of the palms and soles and small areas on the arms and legs. All the deciduous teeth were erupted but they were malformed, carious and irregularly placed. The genitals were large and more adult in type than is usual at 2 years. The liver and spleen were both palpable 2 cm. below the costal margin. He could sit up but could not stand. He was moderately anemic. The Kahn reaction was negative. An increased sugar was the only abnormality in the blood chemistry. The urine showed from 0 to 8 per cent sugar, from 1.018 to 1.045 specific gravity, from 0 to 4 plus nitroprusside and ferric chloride tests, and a faint trace of albumin.

METHODS

Total blood sugars and the nonfermentable fraction were determined as follows: After precipitation of the proteins in the blood with tungstic acid, as suggested by Peters and Van

From the Babies Hospital and the Department of Diseases of Children of Columbia University College of Physicians and Surgeons. A preliminary report of this case was given at the meeting of the American Pediatric Society at Bolton Landing, June 12, 1936. Abstract published in the American Journal of Diseases of Children 52: 1253 (Nov.) 1936.

Slye,¹ total blood sugars were determined on the filtrate by Benedict's² method. This method "determines nonfermentable substances equivalent in reducing power to only 4 to 8 mg. of glucose per 100 cc. blood."³ Somogyi's⁴ method was used in the preparation of the yeast suspension. Since many low values were encountered in the nonfermentable fraction, the concentration of blood and tungstic acid was doubled and this filtrate was fermented for fifteen minutes at room temperature. The fermentable fraction was determined by difference.

Respiratory quotients were determined by the chamber method as follows: Air was blown through the chamber at such a rate that after the patient had been inside for thirty minutes the carbon dioxide content of the air leaving the chamber was less than 1.7 per cent, generally about 1 per cent. Air leaving the chamber was collected in a spirometer for a period of ten minutes after the patient had rested in the chamber for thirty minutes. Duplicate analyses were made of this "expired air" by Carpenter's⁵ method. With the same technic respiratory quotients of alcohol were determined to be 0.667. Frequent analyses of outdoor air gave 0.033 per cent for carbon dioxide and 20.940 for oxygen.

CARBOHYDRATE STUDIES

On a diet that contained 90 Gm. of carbohydrate, 45 Gm. of protein and 50 Gm. of fat, he excreted about 25 Gm. of sugar a day, regardless of the insulin dosage—even when this was

Chart 1.—The effect of 100 units of insulin on the blood sugar.

90 units a day. The fasting blood sugar was always low, varying from 50 to 75 mg. per hundred cubic centimeters. After breakfast the blood sugar rose promptly to an abnormal height, where it stayed until about two hours after supper, when it began to fall steadily. After smaller amounts of insulin had been tried without effect, he was given 100 units of insulin intramuscularly one hour after a mixed meal. As this had no apparent effect on the blood sugar curve, he was given on another day 100 units of insulin intravenously one hour after a mixed meal (chart 1). Again the blood sugar curve showed no apparent effect from the insulin. These results, the low fasting blood sugar and the lack of response to insulin, made it quite certain that the condition was not ordinary diabetes due to pancreatic insufficiency.

Dr. G. L. Foster positively identified the urinary sugar as dextrose. His observations were as follows: 1. Concentration of sugar (as dextrose) by the Shaffer-Hartmann method was 4.84 per cent. Concentration of sugar (as dextrose) by

polariscope was 4.68 per cent. 2. Reduction after treatment with yeast was nil. 3. The employment of phenylhydrazine gave nothing but phenylglucosazone.

To test the patient's ability to metabolize the three important monosaccharides we fed him a diet which contained 97 Gm. of carbohydrate, 10 Gm. of protein and 70 Gm. of fat. One day 90 Gm. of the carbohydrate was dextrose, another day levulose and a third day galactose. The urine excreted between

Chart 2.—The blood sugar curve when the carbohydrate in the diet was largely dextrose.

8 a. m. and midnight contained on the dextrose day 20 Gm. of sugar but on the levulose day only 2.3 Gm. of sugar. The urine excreted between 8 a. m. and 8 p. m. on the galactose day contained 4.4 Gm. of sugar, of which 2.3 Gm. was dextrose and 2.1 Gm. galactose. The fasting blood sugar was low on all three days. On the dextrose day (chart 2) it rose promptly after breakfast to an abnormal height and stayed well above the renal threshold most of the time until evening. On the levulose day (chart 3) the blood sugar stayed below 120 mg. per hundred cubic centimeters the entire morning but was

Chart 3.—The blood sugar curve when the carbohydrate in the diet was largely levulose.

over 160 mg. per hundred cubic centimeters from 3 to 7 p. m. On the galactose day (chart 4) the total blood sugar was high throughout the morning owing to the presence in the blood of large amounts of galactose, but the blood dextrose remained within normal limits until afternoon, when it showed a tendency to rise. These results indicated that the patient could metabolize levulose and galactose much better than dextrose.

In order to be sure that he could convert and store the dextrose producing fractions of protein and fat in a normal

In brief, the results observed were as follows: A low fasting blood sugar. An abnormal rise in blood sugar and glycosuria following the ingestion of carbohydrate that resulted in the absorption of ordinary amounts of dextrose, while the ingestion of isocaloric amounts of levulose or galactose or large amounts of protein or fat caused much less rise in blood sugar and little or no glycosuria. Little or no response to insulin. A normal reaction to epinephrine, the rise in blood sugar being greater when the patient had ingested levulose or galactose three hours before he received the epinephrine than it was when he had ingested dextrose. A rise in the respiratory quotient after the ingestion of dextrose or sucrose in the absence of injected insulin. At no time did he excrete anything like the total amount of sugar ingested.

From these observations it is evident that the patient can and does burn a fair percentage of carbohydrate without the help of injected insulin. In fact, injected insulin does not serve to help him in disposing of the excess dextrose received during absorption. He is, however, able to handle excess carbohydrate absorbed as levulose or galactose. This would seem to make it probable that his difficulty is in the storage of dextrose in the liver. If he can store levulose and galactose much more efficiently than dextrose, it would seem necessary to conclude that there must be some difference in the routes which levulose and galactose travel as opposed to dextrose in the process of storage.

In the process of digestion practically all the carbohydrate in the food is hydrolyzed to three hexoses: dextrose, levulose and galactose. These pass into the portal blood and thence to the liver unchanged. Thus three different monosaccharides enter the liver but ordinarily only one, dextrose, is released from the liver and enters the systemic circulation. However, during the absorption of large amounts of levulose or galactose the systemic blood frequently contains these hexoses in considerable amounts.

Chart 7.—Respiratory quotients before and after the ingestion of sucrose and dextrose.

Just what happens in the liver to the sugar that enters it as galactose and levulose and ordinarily leaves as dextrose is not known. Three possible routes would seem to be open (chart 9): first, levulose and galactose may be converted to dextrose directly. Then they may be stored as glycogen or excreted as dextrose just as is the sugar that enters the liver as dextrose. Second, levulose and galactose may have to be converted to glycogen first and only after they have undergone this conversion may they be changed to dextrose. Third, levulose and galactose may be first changed to some intermediary product, possibly of the three carbon type. After reaching this stage they may be changed to glycogen for storage or to dextrose for excretion.

If the first route is the true one and levulose and galactose are first changed to dextrose, it seems reasonable to suppose that the same mechanisms must decide whether the dextrose from levulose and galactose shall be stored as glycogen or excreted as dextrose that decide this for the sugar entering the liver as dextrose. Thus all three monosaccharides should behave alike ordinarily. The only exception would be when the liver was unable to convert one of them into dextrose. In this case the unconverted sugar would appear in the blood and the urine.

If the second or third route is the true one, levulose and galactose may behave differently from dextrose because of necessity they must first be changed to gly-

cogen or the intermediate product. As soon as this happens they come under the influence of the mechanism that controls glycogenolysis or the conversion of the intermediary product to dextrose. Dextrose, on the other hand, would escape these controls unless it was changed to glycogen or the intermediate product. That the second or third route is the true one is suggested

Chart 8.—Blood sugar curves after the ingestion of 25 Gm. of each of the monosaccharides, showing the effect of 0.5 mg. of epinephrine and 10 units of insulin.

by Cori's⁶ demonstration that levulose forms glycogen as fast as does dextrose. This would seem to be impossible if levulose were first changed to dextrose.

Our patient can apparently store levulose and galactose in an approximately normal manner but he cannot store dextrose as well. It would seem to us that this

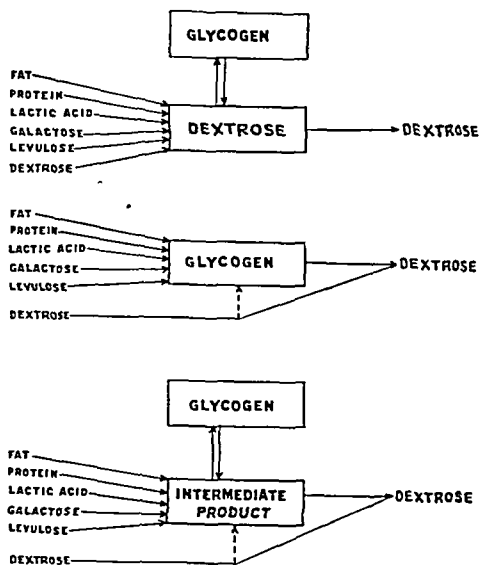

Chart 9.—Diagrams of the three suggested routes of sugar in the liver.

is probably due to his liver's lessened ability to convert dextrose to glycogen or the intermediate product. If this is true it necessitates either the second or third route being the true route. To produce this condition one does not have to suppose that there is anything

6. Cori, C. F.: The Fate of Sugar in the Animal Body: III. The Rate of Glycogen Formation in the Liver of Normal and Insulinized Rats During the Absorption of Glucose, Fructose and Galactose, *J. Biol. Chem.* 70: 577 (Oct.) 1926.

wrong with the mechanism controlling glycogenolysis or the conversion of the intermediate product to dextrose.

Besides the three monosaccharides there are other precursors of dextrose entering the liver in varying amounts all the time. These include lactic acid from the tissues, 58 per cent of the amino acids from the food and tissues, and at least 10 per cent of the fat from the food and body stores. Here again there is little absolute knowledge regarding the route traveled from precursor to dextrose but it is generally believed that they all change to glycogen or the intermediary product, first. This belief is supported by the observations in this case. If this is true and all the precursors of dextrose are, of necessity, first changed to glycogen or some intermediate product and can become dextrose only by traveling this route, it follows that after reaching this stage they are all under the control of the glycogenolysis mechanism, or the mechanism for converting the intermediary product to dextrose. Dextrose entering the liver is the only one that may escape this mechanism, and even it comes under the same control if changed to glycogen.

Our conception of the condition in this patient is that of a marked lessening of the liver's ability to change dextrose to glycogen or the hypothetical intermediate product. On an ordinary mixed diet this results in periodic flooding of the tissues with abnormal amounts of dextrose and at the same time keeps the liver's store of glycogen at a low point, for the excess dextrose in the blood stream instead of being stored is promptly excreted, and after this has happened the small store of liver glycogen is called on to keep up the blood sugar until the arrival of the next flood of dextrose. This is certainly not diabetes mellitus in the strict sense, for it is due to a defective liver function rather than a defective pancreatic function.

Now if we are correct in interpreting our evidence to mean that this patient exhibits no other basic physiologic abnormality, all other departures from the normal state being in his case referable to this single fundamental derangement of liver function, our studies may have wider application, for it now becomes reasonable to infer that in normal subjects the precursors of dextrose are not ordinarily converted directly to dextrose by the liver but that before they can become dextrose they must first be changed to glycogen or some intermediary product. The moment this happens they come under the control of the mechanism controlling glycogenolysis or the conversion of the intermediary product to dextrose. This hypothesis would make it highly probable that one of the functions of insulin is to slow or lessen glycogenolysis or the conversion of the intermediary product to dextrose for the sugar in the urine of a diabetic patient is never levulose or galactose but always dextrose.

It is difficult to make up an adequate diet for a small child that does not furnish considerable amounts of dextrose without making the cost prohibitive. The patient was at home from June to September 1936. His diet during this time was composed of milk (lactose is absorbed as equal parts of dextrose and galactose), banana powder (a considerable part of the sugar in which is levulose), meat, green vegetables and vitamins. On this diet he excreted about 10 Gm. of sugar a day. In the three months he gained 2 pounds (907 Gm.), he began to run about and talk freely and his whole outlook on life changed from that of a sick infant to

that of a normal child. The relatively rapid gain and marked improvement in his general condition would suggest that the change in diet was along the right direction.

SUMMARY

In a case of glycosuria resistant to insulin the glycosuria could almost be stopped by the substitution of levulose or galactose for dextrose in the diet.

There was evidence to show that the patient was able to burn dextrose freely without the help of injected insulin.

It is suggested that the difficulty is due to a marked lessening of the liver's ability to convert dextrose to glycogen or an intermediary product in this conversion.

If our interpretation of the physiologic disturbance manifested by this patient is correct, it is rendered likely that in normal human subjects the precursors of dextrose are all changed to glycogen or at least undergo some preliminary step of this conversion before they can become dextrose. A further interpretation of the evidence presented is that one of the modes of action of insulin is a retardation of the conversion of glycogen or the intermediate substance to dextrose.

Broadway and One Hundred and Sixty-Seventh Street.

SUBCUTANEOUS EMPHYSEMA IN BRONCHIAL ASTHMA

REPORT OF A CASE

J. B. KIRSNER, M.D.

CHICAGO

Subcutaneous emphysema following trauma is a familiar clinical entity and is frequently seen after puncture of the lung by a fragment of bone in a fracture of a rib, in a bullet or stab wound, or around the point of insertion of the needle in artificial pneumothorax. A similar clinical picture has been described after esophagoscopy,¹ tonsillectomy,² extraction of a tooth,³ parturition,⁴ and as a complication of a foreign body in the bronchus.⁵ Many articles have reported this interesting complication following pneumonia (Rush, Adkinson and Hardwick,⁶ Lucke and Meyer,⁷ Sergeant, Launay, Poumeau-Delille and Robert,⁸ Harris,⁹ Jones¹⁰ and Borsarelli,¹¹ among others). Its occurrence after rupture of a viscus¹² and in glass blowers¹³ indicates the wide variety of etiologic factors. Apparently subcutaneous emphysema following bronchial asthma is a rather rare complication. The only case that I have been able to locate in the American literature is that of Kahn,¹⁴ who observed this condition in an 8 year old girl. The two earliest reports have been found in the *British Medical Journal*: Culverly¹⁵ in 1902 described

the occurrence of subcutaneous emphysema in a youth, aged 17, clearing in four days. Whitby¹⁶ in 1905 reported this complication in a man, aged 25, in whom the emphysema was extensive but responded to morphine and tincture of lobelia. More recently MacDermot's¹⁷ case concerns a man, aged 22, who had asthma due to ragweed pollen for six years. During a paroxysm of dyspnea he felt some pain in the upper part of the chest with the development of subcutaneous emphysema in the tissues of the neck. The asthma subsided with palliative treatment and the emphysema disappeared in five or six days. In 1934 Davidson¹⁸ presented a case of subcutaneous emphysema in a 9 year old girl whose asthma had extended over eight years. This was initiated after a severe coughing spell by sudden sharp pain over the anterior aspect of the left upper portion of the chest. There was extensive subcutaneous infiltration of air into the upper part of the chest and back, both shoulders, both arms as far as the dorsum of the hands, both sides of the neck, and the lower half of the face. There was no pneumothorax or other pathologic condition. The asthma was relieved by ephedrine syrup and recovery was complete in one week. In the foreign literature Pastorino,¹⁹ Kruysveldt,²⁰ Artagaveytia²¹ and Scheltema²² have reported other cases of subcutaneous emphysema as a complication of bronchial asthma. This case, then, is the tenth of the kind to be reported.

REPORT OF CASE

E. S., a man, aged 38, an animal (bird) caretaker since 1929 in the Department of Zoology at the University of Chicago,

Fig. 1.—One day after admission, illustrating extent of subcutaneous emphysema.

seen in the Allergy Clinic, Aug. 27, 1936, complained of asthma of six days' duration. August 30, while undergoing investigation in the outpatient department, he returned in an acute

asthmatic attack; this responded very well to epinephrine and the patient felt well enough to return home. However, the attacks recurred with increasing severity; the same evening a slight swelling in the neck was detected. His condition became worse despite his family physician's care and he entered Billings Memorial Hospital August 31. The patient's past history was negative except for a left inguinal herniorrhaphy and a gunshot wound in the left wrist.

Fig. 2.—Ten days later, demonstrating complete disappearance of subcutaneous emphysema.

At physical examination he was propped up in bed, dyspneic and slightly cyanotic. The face was swollen, especially the left side, with the left eye nearly closed. The swelling covered both anterior and posterior triangles of the neck, extending over the anterior thorax to the level of the fifth intercostal interspace, and posteriorly to the angles of the scapulae. This entire area was crepitant. The apex beat was located 9 cm. from the midsternal line. The heart sounds were regular, with a rate of 82. The pulmonic second sound was greater than the aortic second sound. The blood pressure was 128 systolic and 82 diastolic. Diminished tactile and vocal fremitus with dullness was noted over the left lower lung field. Elsewhere were heard coarse vesicular sounds with typical asthmatic squeaks and whistles. Roentgenograms of the chest demonstrated a large amount of air in both supraclavicular regions and in both axillae, and air in the soft tissues of the neck. No air was seen in the pleural cavities; the trachea was in the midline, the heart was not enlarged and the lung fields were clear except for increased markings at the left base. The emphysema progressed down the anterior wall of the chest and along both arms to the dorsum of the hands. Roentgenograms at this time disclosed infiltration of air into the deep fascia of the neck and separation of the individual muscles from their neighbors; also extension into the mediastinum. An infiltrative lesion of the left lower lobe was noted. It was believed that the origin of the emphysema lay somewhere in the inferior mediastinum.

One day after admission, 300 cc. of air was removed by needle aspiration at a point 2 cm. below the right clavicle and from 4 to 5 cm. from the midline. There was a distinct improvement in the next few days. During this time he received 50 cc. of 50 per cent dextrose intravenously and frequent doses of from 4 to 6 minims (0.25 to 0.37 cc.) of epinephrine (1:1,000) subcutaneously. At one time the patient was seized with an acute gripping precordial pain with acute dyspnea; the blood pressure was 136 systolic and 68 diastolic;

an immediate electrocardiogram was normal. This pain gradually abated in several hours and never returned. Eight days after admission the emphysema was noticeably disappearing; the patient's breathing was easier. He was taking fluids by mouth and expectorating large quantities of purulent sputum. The dullness over the left lower lobe was decreasing. His temperature, which had ranged from 100.5 to 104 F., gradually approached normal. Roentgenograms confirmed the diminution of the emphysema but the lesion at the left base was now quite dense and suggested fluid. A laryngoscopic examination was negative. Except for occasional mild pain over the left lower lobe, improvement was steady, and twenty days after admission the patient was discharged well except for slight dullness and slightly diminished breath sounds over the left lower lung field.

Roentgen examination demonstrated that the emphysema had almost entirely cleared save for a small amount of air in the right subclavicular region. There was no change in the lesion at the left base. The right lung was clear. Venous pressures with the direct spinal manometer technic were always normal, except for one occasion when it reached 200 mm. of water during a spasm of especially difficult breathing. The white blood count after having reached 16,100 descended to normal. The urine was normal except for occasional white blood cells. The blood Wassermann and Kahn reactions were negative. About ten days later, x-ray examination demonstrated complete absence of the subcutaneous emphysema; the lesion at the left base had considerably decreased and was believed to represent a localized area of pneumonia. At this time the patient felt very well and physical examination was negative again except for slight dullness at the left base. At a recent check up the patient appeared very well; he had gained 15 pounds (6.8 Kg.) and was symptom free.

RESULTS OF SKIN TESTS

Cutaneous tests to canary, chicken, duck and goose feathers, ragweed pollen and various inhalants were all negative. Similar results were obtained on intradermal testing except for a questionable reaction to chicken feathers and house dust, delayed reactions to catarrhal vaccine and pyrethrum and one plus reaction to ozite.

Material was obtained from the laboratory in which the patient was employed, and testing gave the following results:

Cutaneous tests to chicken feed, chicken mash, floor dust, floor litter (chaff), guinea fowl, hawk, owl and parakeet feathers, pheasant feed, and rowen duck were all negative.

Intradermal tests to floor litter (chaff) +, hawk feather +, chicken mash + +, chicken feed ±, pheasant feather ±, owl feather 0, parakeet feather, diluent —.

ADDENDUM.—The patient was last seen on March 29, 1937, at which time he was in good health, having regained his usual weight of 180 pounds (82 Kg.). Since wearing a mask during his work in the laboratory, he has been free of any respiratory difficulty.

COMMENT

The pathologic physiology of this condition would seem to be based on the rupture of pulmonary alveoli as a consequence of increased intrapleural and intra-alveolar pressure occasioned by the marked difficulty in expiration, typical of bronchospasm. The rupture of an emphysematous bleb or of a cavity apparently permits air to extend through the interstitial tissue of the lung into the loose cellular tissue of the mediastinum and from there to the subcutaneous tissue of the neck and face and over the entire body. The courses that air may take in the production of mediastinal and subcutaneous emphysema have been especially well studied experimentally by Ballon and Francis.²³ They have pointed out some of the consequences of increased mediastinal pressure, particularly the hyperventilation or hypoventilation of the lungs—stagnation of blood in the pulmonary bed, edema of the lungs and development of fluid in the pericardial cavity. In this particular case, hypoventilation could well explain some of the respiratory difficulty; none of the other com-

plications were observed. My normal results with venous pressures are consistent with the results of other investigators in this respect. The significance of the area of consolidation in the left lower lobe seems difficult to evaluate. Interstitial emphysema following influenzal bronchopneumonia has been noted by Kountz and Alexander,²⁴ Kelman²⁵ and Harris,⁹ among others. Its occurrence has been attributed to toxic action of the infecting agent on the lung parenchyma, on the respiratory center producing dyspnea, cyanosis and resultant emphysema²⁵ and to ulceration of the bronchial mucous membrane.⁹ In the present case it would seem that the acute asthma was the primary factor in the development of the clinical picture with the pulmonary consolidation a secondary complication.

SUMMARY

1. Subcutaneous emphysema is a rare complication of bronchial asthma.
2. The emphysema in this case was probably due to the rupture of emphysematous blebs into the inferior mediastinum.
3. Symptomatic treatment and the usual measures employed in acute bronchial asthma are generally successful.

BIOPSY STUDIES OF HUMAN ENDOMETRIUM

CRITERIA OF DATING AND INFORMATION
ABOUT AMENORRHEA, MENORRHAGIA
AND TIME OF OVULATION

JOHN ROCK, M.D.

AND

MARSHALL K. BARTLETT, M.D.

BROOKLINE, MASS.

Interest in the factors of female fertility has led us to a study of the endometrium, for among the cyclic changes in this tissue is written the story of the patient's menstruation, and from this we have traditionally sought insight into her ovarian behavior. Long before modern endocrinology a close association was recognized between uterine flow and fertility. Of late we have enjoyed the demonstration of causal relationship between the hormones of the follicles and of the corpus luteum on the one hand and of changes in the endometrium on the other. Work done in both the clinic and the laboratory shows that estrogen is the specific hormone of the growing and ripe follicle and that it causes proliferation of the endometrium. This is a true growth of the mucosa evidenced by many mitoses in the glandular epithelium, an increase in the number and complexity of the glands and an increase in the thickness of the whole tissue. It is learned too that the corpus luteum, which normally forms in the follicle only after its rupture and ovulation, secretes among other hormones the same estrogen and its own hormone, progesterin, which causes specific changes in the proliferated and sensitized endometrium. The latter changes, which are attributed to progesterin and are called secretory or functional, consist of certain cytologic variations in the glands and stroma of the uterine lining.

23. Ballon, H. C., and Francis, B. F.: 8. Consequences of Variations in Mediastinal Pressure: Mediastinal and Subcutaneous Emphysema, *Arch. Surg.* 19: 1627-1659 (Dec. 1st. 21) 1929.

If one accepts the causal specificity of these mutations among the cells of the endometrium, that proliferation or growth of the glandular epithelium is the specific effect of estrogen, which comes in appreciable amounts only from the functioning follicle, one can reason backward and conclude that if the endometrium has these characteristics there is in one ovary at least one functioning follicle. And if one accepts the demonstration that progesterin, which comes only from the corpus luteum, is the specific and only cause of secretory or functional changes in the glandular epithelium, one may likewise conclude that if the endometrium is found in such a secretory state there is at least some functioning corpus luteum in at least one ovary.

As, for a working basis, we have accepted these two causal specificities, that of estrogen on proliferation and of progesterin on secretion, we have attempted to ascertain the condition in the ovaries by study of the endometrium.

For such a study we have used biopsies of the endometrium obtained by the small suction curet. To use this instrument profitably and to interpret the curettings correctly require recognition of the fact that all parts of the uterine lining and all levels of the endometrium do not partake synchronously or in the same degree in the proliferative and secretory activity mentioned. We believe that it is in only the mucosa from high on the anterior or posterior wall of the fundus that the cytologic changes specified occur with consistent accuracy and progression. Furthermore, even in specimens from these portions of the uterus, correct interpretation can be made only from the most superficial layer of the endometrium. Diagnosis is complicated even more by the fact that the endometrium, especially in hyperplastic conditions and in the late secretory phase, is not a flat smooth tissue but lies in irregular ripples over the subjacent myometrium. The day by day changes in the epithelium of the mounds and the valleys are not always of exactly the same degree. Fortunately one can ascertain by the arrangement and number of

at least three times as much tissue. The larger surgical curet is also less useful even apart from its size, which requires dilation of the internal os. It traumatizes the tissue much more than does the smaller suction instrument. As the localization of the specimen and the finer dating of secretory specimens depend on the amount of edema and of internuclear cytoplasm in the stroma, and on the arteriolar proliferation and the condition of the

Fig. 2.—Early proliferation. Simple, small glands with low columnar epithelium and absent or beginning pseudostratification. Many mitoses. Fairly dense stroma. Small stroma nuclei with little if any cytoplasm.

perivascular stroma cells, the blood that the gross curet sets free in the tissue frequently constitutes a blinding hemorrhage. The smaller instrument can be used week after week to follow the development of the endometrium, for the damage it does to the tissue is slight and quickly repaired. Furthermore, it obtains only the useful superficial portion of the endometrium and not the deeper layers, in which the specific cyclic changes are not so regular or extensive. Such biopsy is a short office procedure rarely requiring anesthesia, and then not more than 3 cc. of 10 per cent solution of the sodium salt of n-methyl-cyclo-hexenmethyl barbituric acid, given intravenously. This renders the patient unconscious for the requisite two minutes. Complete recovery, sufficient to permit leaving the office, seldom requires more than ten minutes.

To characterize deviation from normal menstruation, we have used the following terms: normal menstruation to mean uterine bleeding in cycles not shorter than twenty-four days nor longer than thirty-one days, lasting at least two days and at most seven days and requiring at least two napkins for at least two days; oligomenorrhea or "few catamenia" to mean cycles habitually longer than thirty-two days and not usually longer than three months; polymenorrhea or "many catamenia" to mean cycles habitually shorter than twenty-four days; hypomenorrhea or "diminished flow" to mean bleeding requiring less than two napkins for less than two days; hypermenorrhea or "increased flow" to mean bleeding requiring more than six napkins for more than five days; amenorrhea, to mean absence of uterine bleeding for periods not less than three months; metrorrhagia, to mean bleeding quite irregular in interval, duration and amount, and aperiodomenorrhea or "irregular catamenia" to mean bleeding in cycles sometimes shorter than twenty-four days and sometimes longer than thirty-two days, a combination of oligomenorrhea and polymenorrhea.

Of the 900 biopsies from which this study was made, only 457 biopsies from 329 patients are here discussed,

Fig. 1.—Hypoplasia of endometrium. Biopsy obtains long ribbons of superficial epithelium and little if any stroma. Few, if any, tiny glands. All the sections presented are reduced from photomicrographs with a magnification of 100 diameters.

glands at the various stages of growth, by the quality of the stroma, and by the presence or absence of the superficial covering epithelium whether one has obtained tissue from the desirable loci or not.

Because even from these most favorable places the picture varies slightly, we believe that the punch biopsy is less serviceable than the suction curet, which obtains

Several hundred other biopsies from these and other patients are not included because the ancillary data were insufficient; because the biopsy had been preceded by organotherapy, which may have changed the natural endocrine balance; because they were uninformative repetitions of previous observations, as in repeated specimens from an unchanging amenorrheic endome-

Fig. 3.—Late proliferation. Simple, moderately dilated glands with columnar epithelium and pseudostratification and occasional mitotic figures. Stroma cells low in cytoplasm. Extravasation of erythrocytes, possibly traumatic.

trium, and in about fifteen cases because the specimen was inadequate for satisfactory examination. The tissue drawn into the curet was washed out and hardened in solution of formaldehyde, then cut in celloidin to a thickness of 14 microns and stained with hematoxylin and eosin. Specimens are diagnosed arbitrarily on the basis of a twenty-seven day cycle with ovulation on the fourteenth day, corpus luteum effect on the fifteenth day and menstruation on the twenty-eighth day. We have worked out our own criteria for diagnosis of the

Fig. 4.—Seventeen day endometrium. Further rippling and dilatation of glands. Stroma still generally dense. Stroma nuclei almost nude. Marked change in epithelium of glands. In the glandular epithelium there is a central migration of the nuclei, leaving a well marked lucid zone behind.

specimens, with some assistance from the previous work of Schroeder¹ in Germany. We have derived valuable assistance also from studies made here by Bartelmez²

and by O'Leary.³ We do not claim exact accuracy. We believe, however, that it is possible to detect even a slight progestin influence and that it is justifiable, when this is found, to assume ovulation as having occurred. Furthermore, we believe it possible to read in the endometrium the duration of progestin effect and thus ascertain the age of the corpus luteum, and possibly the normality of balance between progestin and estrogen in the blood. To determine, in the presence of imbalance, just which factor is deficient may be possible when more is learned of just which cytologic effects during the functional phase of endometrial activity are attributable to each hormone. Some are known already, as I hope to show; many must still be hidden from us.

The characteristic endometrium of the established menopause and of most long-standing cases of amenorrhea, with its thin, superficial epithelium, its thin stroma and paucity of relatively small and simple glands yields to the curet only the topmost epithelial layer and stroma with a depth of only a few cells (fig. 1). In the last three years we have come to know that from this hypoplastic endometrium alone does the curet fail to obtain more stroma and glands and so confidently diagnose hypoplasia when only such a tiny

Fig. 5.—Nineteen day endometrium. Slightly more generalized edema of stroma. Nuclei still with little cytoplasm. Glands practically as before except for epithelium.

specimen is obtained. From this we deduce a failure of follicle formation and of estrogen production. Estrogen effect is readily seen in the larger specimens, which include stroma and glands. After the third day of menstruation the epithelium of the glands, which was cuboidal, quickly becomes columnar with pseudostratification of the nuclei and frequent mitoses. The glands at first are uniformly small and simple. While they remain thus we call the endometrium early proliferative (fig. 2). Later when the stroma nuclei increase a little in size, the glands become larger and wavy and the epithelium becomes high columnar with marked pseudostratification and frequent mitoses, we diagnose late proliferation (fig. 3). When we find such glandular epithelium lacking in mitoses or containing only an occasional mitotic figure in a rare gland, we arbitrarily classify it as a fourteen day specimen. If signs of continued growth, as evidenced by many mitoses in pseudostratified columnar epithelium, occur in plentiful dilated distorted glands placed in relatively thick stroma, the diagnosis of fourteen day hyperplasia is made. If such glands vary widely in size, especially if some are

cystic—that is, are large, round and with flattened epithelium—we call it fourteen day dysplasia, of which Novak's "swiss cheese" endometrium is an example.

We have not been able to make day by day classification of proliferating endometrium, that of the estrogen phase of the ovarian cycle. We see an appreciable difference by the concentration and size of glands and by the gland epithelium between the six day endometrium and that of the twelfth day, but among the first eight days and among the last six we cannot define exact criteria. We therefore limit our classification of normal proliferating endometrium to the types mentioned: "early proliferating," when they resemble a six day type; "late proliferating" when they more closely resemble a twelve day type, and "fourteen day" when proliferation has been accomplished and mitotic figures are scarce.

From the fourteenth day on to the twenty-seventh and menstruation, classification is much simpler, although we make no claim to exact accuracy. The first sign of progestin effect, which we arbitrarily place on the fifteenth day, is seen in vacuolization of the cytoplasm and beginning migration of the nuclei toward the sur-

From the twenty-first day onward the telltale signs are seen not primarily in the glands but in the stroma and vascular system. The first change was edema, which has become generalized by the twenty-first day, each stroma nucleus being separated from its fellow and bare of all but a slight trace of cytoplasm, which streaks outward in irregular internuclear fibrils. The cross

Fig. 7.—Twenty-three day endometrium. The stroma cells near the thick walled arterioles, especially, and in dispersed units acquire more cytoplasm.

section of groups of small arterioles is seen lying among the glands. Two days later, on the twenty-third day (fig. 7), a marked change has begun in the stroma cells and in the walls of the arterioles. The latter are larger and the walls thicker. They are more numerous, and single vessels are seen coursing upward and tangential to the superficial epithelium. Most interesting is the increase in the cytoplasm of the stroma cells. This begins in those near the arterioles and on the twenty-third day is well marked. By the twenty-fifth day

Fig. 8.—Twenty-five day endometrium. Large groups of stroma cells acquire more cytoplasm, especially near the arterioles. Those in the edematous areas are also larger. The arterioles are very prominent.

face of the cells, leaving a lucid zone underlying the nuclei. Two days later (fig. 4) this zone is well marked and the nuclei above it are lining up to lie later each beside the other near the middle of the cell. Two days later, on the nineteenth day (fig. 5), this has been accomplished and the row of nuclei has sunk distally near to the base of all the cells. Until after the next day an occasional group of nuclei will still be seen proximal to a small "zona pellucida."

Noticeable about the eighteenth day is a beginning edema of the stroma, first in patches a slight distance below the superficial epithelium. This spreads until it is generalized by the twenty-first day (fig. 6), the day on which the last vestige of the "zona pellucida" has disappeared. On the twenty-first day also the process of "secretion," which began about the seventeenth day, is well advanced. This is seen as a swelling of the epithelial cells, including the nucleus, and at first a progressive vacuolization of the cytoplasm overlying the nuclei and then a fraying of the cell margins as of breaking of the vacuoles into the lumens of the glands. These dilate and their epithelial borders become serrated, as if from crowding of the enlarged epithelial cells.

(fig. 8) this process has increased in amount and extent until much of the stroma is affected. The edema is replaced by masses of contiguous large cells with large pale nuclei and much cytoplasm. The next day, the twenty-sixth (fig. 9), the increase in the size of stroma cells has extended so that almost all the interglandular cells are contiguous.

On the twenty-seventh day (fig. 10) this solidification of the most superficial stroma becomes complete. Many

cells are indistinguishable from young decidual cells. Indeed, they are such. The glands are widely dilated and the epithelium, rid of most of its cytoplasm, approaches the cuboidal. The vascular system is highly developed and the arterioles and venules are engorged with blood. This is the predeciduum, and catamenia is at hand.

The first sign of this event, which again arbitrarily we place on the twenty-eighth day, is an influx of

Fig. 9.—Twenty-six day endometrium. Cytoplasm of stroma cells increases so that cells become contiguous in ever-widening areas. Nuclei are larger and stain less deeply.

lymphocytes and polymorphonuclear leukocytes. These are present in the endometrium always, but normally in small numbers. They are not significant for diagnosis until about the twenty-fifth day, when they become more numerous. Late on the twenty-seventh day, just before menstruation, they appear in great numbers, being plentiful at first just beneath the superficial epithelium. Erythrocytes too are present at all stages, some because of trauma but some, we believe, normally. Rather abruptly just before menstruation, or as we would say late on the twenty-seventh day, these increase in number. They appear in clumps and, here and there below the superficial epithelium, in rows as well as clumps. This extravasation of red blood and mobilization of lymphocytes extends until the whole predeciduum is infiltrated, the stroma nuclei become pale, neutrophils appear in large numbers, the tissue is disintegrated and menstruation occurs. Such is the picture on our twenty-eighth day, which we also call first day and catamenia.

There is much practical value in this method of studying the endometrium. We have dwelt on the simplicity of obtaining the tissue. The differential diagnosis between proliferating and secreting endometrium—the former showing only estrogen influence and the latter both estrogen and progesterin effect—is also quite simple. We still find diagnosis of proliferating endometrium by days impossible, although, as has been said, there is an easily detectable difference between early proliferation and late proliferation. The day by day diagnosis of functional endometrium on an arbitrary scale, as for a twenty-seven day cycle, with ovulation on the fourteenth day, is not impossible. We believe with improvement of technic and criteria that it can be done, and with an accuracy of within one day.

For the rational clinical use of even the few potent preparations of gonadotropic substances, estrogens and progesterin already available, this method of diagnosis is of great value. It will help too in the formation and the testing of theories. By it one can determine whether

and when a patient ovulates, and, if she is anovulatory, whether any of the gonadotropic substances either from the pituitary gland or from pregnancy urine is effective. Hypoplasia may be accurately diagnosed and treatment objectively evaluated. One may perhaps determine also the integrity of the corpus luteum; i. e., whether it secretes progesterin in an amount normal in itself or in normal relation to the amount of estrogen present and for a normal length of time.

Biopsies studied in various specific conditions of abnormal menstrual behavior have furnished some interesting data; for example, in amenorrhea. Forty-eight biopsies were made on thirty-six patients with amenorrhea; i. e., patients who habitually passed at least three months without flow. Half of these showed hypoplasia, one third showed a proliferating endometrium and one sixth showed signs of having ovulated. All the latter had flowed within six months prior to the biopsy; their amenorrhea had not been of long standing. There were only five such biopsies showing secretion, from five different patients. The subsequent history of two of these we do not know. Three of them flowed soon after biopsy. We believe that the others did also, because of over 300 biopsies which showed secretory endometrium and of which we have subsequent information, only two were not followed within sixteen days by flow, and one of these two flowed on the twentieth day. We can find no evidence, in biopsy studies, of the existence of a persistently functioning corpus luteum in human beings. Even the one patient just mentioned, who did not flow after a secretory endometrium was found, subsequently showed a proliferating endometrium without evidence of function, although no gross flow intervened. As in all mammals below the primates, her endometrium regressed without flow. We believe that in the absence of pregnancy persistent corpus luteum is never an explanation of amenorrhea.

The estrogenic phase of endometrial development on the other hand may persist almost indefinitely without

Fig. 10.—Twenty-seven day endometrium. The predeciduum. The interglandular stroma is solid in large areas. The cells are indistinguishable from young decidual cells. There is beginning infiltration of lymphocytes. The glands have cuboidal epithelium.

menstruation, five of our sixteen biopsies that showed proliferation having been taken over a year after the last flowing; five other patients did not flow following the biopsy. Many patients with long standing amenorrhea, then, have a high degree of follicular activity and offer good prospects for clinical relief.

A failure or an extremely slight degree of follicle formation is found to be the cause of most long stand-

ing cases of amenorrhea and may easily occur in patients who flow infrequently during any year.

We have fifty-four biopsies from forty-five patients in whom flowing was increased and so irregular in volume and incidence as to warrant a diagnosis of metrorrhagia. Only three of these showed deficient follicle formation. One half showed evidence of good follicular activity and slightly less than one half showed signs of ovulation almost irrespective of the time

Fig. 11.—Biopsy may have precipitated flowing in this patient, who had been amenorrheic for more than one year. She flowed four times with fair regularity, the last time, however, without preceding biopsy. Examination showed that at least the first three periods were anovulatory, as, in spite of flowing, the endometrium remained stationary in a late proliferative phase.

clapsing between the last flow and the biopsy. Thus we learn that patients may flow excessively and irregularly with any degree of endometrial development. The mere presence of a functioning corpus luteum will not prevent metrorrhagia, nor will hypoplasia of the endometrium. By this method of study it is possible to distinguish between the patient with irregular catamenia and hypermenorrhea and the patient with dysfunctional uterine hemorrhage who does not ovulate—an important distinction to make if there is complaint of sterility.

An engrossing aspect of these studies is the light they throw on the question of the ovulation time in women.

We have 222 biopsies of postovulatory endometrium for which we know the date of the preceding menstruation. We are unable to correlate the dating on our arbitrary plan (that is, for a twenty-seven day cycle with ovulation on the fourteenth day) with the date of the preceding menstruation except in moderate degree for those largely selected cases in which we expected conformation and in which biopsies which were dated older than the twenty-fourth day were obtained. This lack of correlation is not surprising, since we have found what many others have shown that full proliferation may persist in the endometrium almost indefinitely and regardless of flow, suggesting the indefinite persistence in the ovary of ripe follicles capable of ovulating any time, even during an anovulatory catamenia. (Such may offer the explanation of those rare cases of fertilization occurring just before, during or after what seemed like normal menstruation.)

We have 200 biopsies of postovulatory endometrium for which we know the dates of the succeeding menstruation. This is shown in the accompanying table.

Among these biopsies we find an impressive agreement with the theory attributed to Ogino and Knaus. If we insist that ovulation takes place on the fourteenth day before menstruation, only 15.5 per cent of our biopsies are correctly dated. This is not as inaccurate as it seems, for the chance of menstruation occurring on any single subsequent date is immeasurably less than 15.5 per cent. If we accept the proposition that ovulation occurs from the twelfth to the sixteenth day before menstruation, our dating is found correct in 70 per cent of the biopsies, when the chance for error was almost infinity. If we are allowed an inaccuracy of one day in the dating, we conform to the theory in 87.5 per cent with the same chance factor of almost infinity. Correction of these figures by omission of cases in which the flow occurred on the day of the biopsy and was possibly precipitated by it, or of those largely selected cases in which the specimens were dated over the twenty-fourth day, or omission of both such groups, does not materially change the percentage of correct dating. Conversely, if one can accept the accuracy of our dating, the Ogino-Knaus theory applied to about 75 per cent of our patients.

For consideration of the latter point, it should be remembered that almost 81 per cent of the patients recorded are between 25 and 40 years of age and 63 per cent are between 25 and 35; furthermore, that they all menstruate with moderate regularity. From our biopsy data, then, the most we may at present say is that regularly menstruating women between the ages of 25 and 40 have a 75 per cent chance of ovulating between the twelfth and sixteenth days inclusive before the succeeding menstruation.

Any method of transcervical approach to the endometrium seems to have one potential quality that is good or bad according to the purpose of the instrumen-

Ogino-Knaus Theory: Corpus Luteum Functions for Twelve to Sixteen Days Before Catamenia *

		14 Days	12-16 Days	11-17 Days
All cases.....	Correct	31 (15.5%)	149 (70%)	167 (81.5%)
	Incorrect	169 (84.5%)	60 (30%)	33 (16.5%)
Omitting all cases dated over 24th day	Correct	35 (4.7%)	51 (48.8%)	78 (73.6%)
	Incorrect	101 (95.3%)	55 (51.2%)	28 (26.4%)
Omitting cases in which flow occurred on day of biopsy	Correct	31 (18.7%)	118 (71.3%)	141 (85.4%)
	Incorrect	134 (81.3%)	47 (28.5%)	24 (14.6%)
Omitting both the above groups	Correct	5 (5.1%)	51 (32.5%)	78 (70.1%)
	Incorrect	92 (94.9%)	46 (47.5%)	19 (29.9%)

* The figures show relative accuracy of theory and dating. If the Ogino-Knaus theory is correct then the dating of biopsies is correct in percentages given; if the dating is correct then the theory applies in percentages given. The eleven day group allows for a mistake of one day in the dating.

tation. In some mysterious and unpredictable way it sometimes, not always, changes the existing hormone setup. A patient with amenorrhea of persisting abnormal proliferation may flow not immediately or only once but sometimes in apparent cycles and without ovulation (fig. 11); or a patient with a similar failure of ovulation with or without flow may suddenly ovulate, as if from the effect of the biopsy.

These phenomena raise many questions that tempt digression. Is there in the cervix a nodal point of the autonomic nervous system whereby the anterior pituitary dynamo may be effected? Labor, which may or may not require the anterior pituitary, is often induced by cervical stimulation. What is the relationship between these phenomena and that of ovulation induced in the isolated mature doe by cervical stimulation? Similarly, is the slight traumatization of the endometrium in some of these patients conducive to an unusually extensive decidual response, as is seen in the pseudo-pregnancies, induced in like manner in some laboratory animals, and does this augmented reaction offer to some sterile patients a more serviceable placental site?

Whatever may be the method or explanation of these apparent consequences of endometrial biopsy, one must keep in mind the possibility of such an influence when interpreting the menstrual behavior following its use. The incidence is not constant or, we believe, so common as to destroy the utility of this method of study if applied to a very large number of cases.

Many other interesting observations have been made in these studies. Eight cases of tuberculous endometritis in sterility patients, seven of these quite unsuspected, were found. Two biopsies showed cancer of the endometrium, one of these in a patient only 35 years of age and quite unsuspected. Mallory Sr. confirmed this diagnosis. In three biopsies evidence of early pregnancy was found. One biopsy was due to a mistake in selection of patients by mixing of records in the clinic. No great harm was done. One patient gave a history which warranted clinically a diagnosis of metrorrhagia. She was, conceivably—shall we say—malingering. Another was a widow whose wishful thinking misled us. Her pregnancy was not interrupted by the biopsy.

SUMMARY AND CONCLUSIONS

The suction biopsy is a very useful method of endometrial diagnosis, better, we believe, than the punch biopsy or curettage. The specimen should be taken from high on the anterior or posterior wall of the corpus, for only here are cytologic changes complete and progressive.

Two phases of endometrial development during the menstrual cycle are cytologically distinguishable: the proliferative, attributable to estrogen, which shows well marked differences between its earlier stage and its subsequent development; the second, the secretory phase, attributable to both estrogen and progesterin. During this phase, mutations in the glands and their epithelium in the stroma and its cells are characteristic of successive days and make possible a day by day appraisal of corpus luteum activity.

Such dating of the endometrium on an arbitrary scale as for a twenty-seven day cycle with ovulation on the fourteenth day is useful for determination of ovulation, for diagnosis in menstrual disturbances and for evaluation of endocrine therapeutics.

Amenorrhea is usually due to deficient follicular development but may be present even though a proliferative endometrium shows a high degree of follicle activity and rarely in the presence of cyclic ovulation, as in subprimate mammals. We believe that in the absence of pregnancy there is never a persistent corpus luteum.

Metrorrhagia, too, may occur with any degree of endometrial development and therefore in spite of ovulation and corpus luteum formation.

Biopsy studies show that in human beings the follicle phase is variable within extremely wide limits but that at least 75 per cent of women between the ages of 25 and 40 have a corpus luteum phase of from twelve to sixteen days.

COMPARISON OF METHODS OF ROENTGEN EXAMINATION OF THE COLON

JAMES T. CASE, M.D.

CHICAGO

Twenty-nine years ago I gave my first opaque enema under fluoroscopic screen control. The publications of Pfahler and a few references from foreign literature constituted the stimulus for the undertaking. Bismuth subnitrate was the opaque salt, suspended in buttermilk. The chief aim of the study was to determine the position of the transverse colon and of the right and left colic flexures. To emphasize the contrast presented by the elaborate roentgen study of the colon as practiced now, with indications for its use covering a very wide range of pathologic possibilities, I was asked to offer a review of the evolution of the technic of x-ray examination of the colon, followed by an evaluation of the different methods.

Routine practice in intestinal x-ray examinations includes the opaque meal, with appropriate screen or film observations of the opaque residues as they move along the large bowel (fig. 1), followed by the contrast enema (fig. 2) administered under screen control by the physician-radiologist himself, with appropriate film records during the course of the fluoroscopy, and subsequent observations after the patient has attempted to expel the contrast fluid. The combination of these two

Fig. 1.—Carcinoma of transverse colon easily recognized on the film following an ordinary barium sulfate meal. Easily seen on the fluoroscopic screen.

series of observations constitutes what we are pleased to call a complete gastro-intestinal roentgenologic study. Much of its value lies in the fact that it is done as a routine, and this routine is justified by the frequency with which colonic lesions are encountered when only pathologic conditions of the upper part of the abdomen are suspected and vice versa. The same justification exists for a routine complete gastro-intestinal x-ray study in every case of suspected lesion anywhere in the

From the Department of Radiology, Northwestern University Medical School.

digestive tube as there is for the complete clinical work up considered good and accepted procedure in the general examination of any patient. There is the difficulty of financial objections in many cases, but radiologists have made a sincere effort to cooperate with the other clinicians in keeping their services within reach of the needy.

On the whole, it may be said that the colonic study with the opaque meal gives information more espe-

Fig. 2.—A case of multiple diverticula of the colon with obstructing peridiverticulitis, illustrating the difficulty in passing the opaque clyisma higher than the obstruction, although with a previous barium sulfate meal, residues of which are seen in the diverticula, no obstruction was noted. It is not wise to persist in the attempt to fill the colon by enema.

cially regarding function, whereas the contrast enema affords data relating to organic lesions, the two methods overlapping somewhat in their usefulness and yet often supplementing each other in a very precise manner. The opaque meal study is time consuming, sometimes extending into three days, whereas the contrast enema or some elaboration of it can be accomplished within a short time in one day. The presence of such a condition as anal insufficiency may necessitate the use of the barium meal study even though the contrast clyisma would be the method of preference. There is also a use for the oral contrast method, preferably by the employment of umbrathor, in cases in which the contrast enema has revealed a serious obstruction and the radiologist does not wish to force passage of the stricture and yet wishes to obtain information regarding the digestive tube proximal to the stricture. Haenisch of Hamburg, a pioneer in this work, in 1911 called attention to the fact that in many cases of colonic obstruction the stricture offered little hindrance to the passage of relatively dense bowel residues coming from above while resisting the passage of the fluid contrast enema (fig. 2); he thought that the long continued effort of the colon to force fecal residues caudad through the narrowed lumen resulted in the development of a funnel effect, which operated to offer a valvelike opposition to the ascent of the fluid enema. Umbrathor, being an aqueous solution of thorium dioxide, remains fluid and presents no possibility of impaction above a stricture, an accident needlessly feared if one takes the precaution to follow up the examination with subsequent

observations to note possible impaction. Finsterer saw no objection to barium sulfate for this study, for, if impacted, it could be removed by the operation that was indicated in any event. However, the use of the aqueous solution instead of the opaque salt suspension removes this objection entirely.

The contrast meal had its inception early in the history of roentgenology through the work of Cannon and Williams, Hemmeter, Rieder, Pfahler and a host of others. Air injections into the colon were practiced as early as 1907 (Pfahler, Cole and others) principally for the purpose of studying the relationship of intra-abdominal tumors lying outside the digestive tube and to afford greater visibility of the liver, spleen, gall-bladder and kidneys, the increased translucency of the air-distended bowel offering a marked contrast to the denser shadows of the organs or tumors in question.

The efforts of Pfahler and of Cole, and especially the work of Haenisch published in 1910 and 1911, definitely established the contrast enema as a dependable method of colonic diagnosis, especially in relation to gross pathologic alterations. Various improvisations of apparatus were utilized for the screen study of the contrast enema, the final and best known one being the "trochoscope" of Haenisch, the forerunner of the present day horizontal fluoroscope, widely adopted, and copied and improved. Roentgenoscopy was also greatly facilitated by the introduction of the author's foot switch, automatically cutting off the room illumination whenever the x-ray current was turned on.¹ With the fluororadiographic switch it became easy to turn the patient or tilt the table to any desired degree during the course of the screen study and to make appropriate film records without loss of time. As early as 1909 this technical procedure became a part of our routine practice. The single contrast enema, thus employed under roentgenoscopic control, is the most expeditious, simple, convenient and generally useful method of study of colonic morphology. It should be administered by the

Fig. 3.—Simple opaque enema, followed by expulsion of as much as may be possible, often reveals the site of obstruction and its nature without resort to more complicated diagnostic x-ray studies. In this case there is a carcinoma of the lower sigmoid, not as yet offering any serious obstruction.

roentgenologist himself at a rate sufficiently slow to allow adequate screen study and such fluororadiographic film records as seem required. One hears of instances

1. The author believes that in 1909 he was a pioneer in the use of such a foot switch. He later described to the engineers of a well known concern manufacturing x-ray apparatus his desire for a double fluorographic foot switch, one pedal being for use in fluoroscopy at around 5 milliamperes of current, the other for radiographic work at 50 milliamperes or more, as required. The fluoroscopic pedal also extinguished the overhead room light whenever the screen was in use. The controls were arranged before beginning the screen study, so that at any moment during the course of the fluoroscopy it was easy to interpose a cassette and make an instantaneous film record (recently called "spot film") of any desired phase of screen observations without a moment's delay. From this request was evolved the present fluororadiographic switch, which adds so much to the comfort and facility of roentgenoscopy of the colon.

in which a nurse technician or other lay assistant administers the opaque enema as she would an ordinary cleansing enema, after which the patient is removed to the roentgenographic table for a film. But this is faulty practice; it is imperative that the eyes of the physician radiologist should follow every inch of the ascent of the opaque column, for his experience and medical train-

Fig. 4.—Illustration borrowed from Schinz showing diagrammatically the three rows of colonic haustra. It sometimes occurs that only two rows are visualized with opaque material, the other row being filled with stagnant nonopaque material or with gas. Under such circumstances it is possible to make an erroneous diagnosis of colon polyposis.

ing will enable him to recognize and record roentgenographically aberrations from the normal (fig. 10) which would not be otherwise discovered even on the final films. From my earliest roentgenoscopic studies on the colon it has been my practice, as a necessary part of the procedure, to turn the patient into the left oblique position (figs. 8, 11 and 12) and often also to the right, to observe the filling of the rectum and sigmoid and to make film records ("spot films") with the film cassettes placed in the most favorable position under screen guidance and exposed without interruption of

Fig. 5.—Roentgenogram made at once after evacuation of the ordinary opaque enema. A record of this kind, when the enema has been successfully expelled, demonstrates the elasticity of every inch of the colonic wall and the fact that the lumen is clear of tumors. (Contrast this film with figure 6, which under similar circumstances shows a tumor in the right half of the transverse colon.)

the fluoroscopic examination. Straight lateral films of the rectosigmoid are sometimes helpful in recording for later study the appearance of the posterior wall of the rectum, which would otherwise be missed because of the impossibility of proper fluoroscopic vision through such dense parts.

Preparation of the colon by preliminary cleansing of fecal residues seems ideal. A day or two of liquid petrolatum by mouth or perhaps even an ounce (30 cc.) of castor oil, followed by enemas in the early morning the day of the examination, causes the least disturbance of colonic function. As a matter of practice the cleansing preparation is not usually requested, for recognition of the residual accumulations of intestinal content through the defects in an otherwise uniformly even density of the contrast shadow of the colon at once furnishes data concerning colonic stasis and gives some aid in determining the type of constipation.

A careful analysis of the problem postulated in each case will often lead to the opaque enema as the first x-ray procedure in the study of a suspected colonic lesion. This is true whenever the lesion is thought to be of an obstructive or potentially obstructive nature, when the retention of the accumulated opaque materials from the previously given opaque meal above the site of

Fig. 6.—After attempt at colonic evacuation after opaque clysis, it is easily recognized that the right half of the transverse colon is the seat of an irregular filling defect around which barium residues are noted. Serial films over this part of the colon, made during fluoroscopy, confirmed the diagnosis of carcinoma.

obstruction might prove embarrassing. For example, if carcinoma of the colon is suspected, one proceeds at once to the contrast enema, supplementing it later by air injection and stereoscopic films should the conditions seem to indicate.

It remained for Fischer in 1923 to popularize the idea of the double contrast method, combining the contrast enema with air insufflation of the colon. His technic required the introduction of the ordinary contrast enema of about 1 liter, administered under roentgenoscopic control and assisted by manipulation with the palpating hand or by turning the patient, after which a roentgenogram was made. He then proceeded to make an inflation of the colon without much regard for possible overdistention, although he did sometimes allow the patient partially or completely to evacuate before injecting the air. His patients were prepared by preliminary administration of a laxative sufficient to clear the colon of all foreign material, sometimes supplemented by cleansing enemas. Fischer introduced the enema by the gravity method and the air by an ordinary handblower. He thought a mixture of about four parts of air to one of opaque clysis desirable, and he placed the patient in whatever position was most suitable for

demonstrating the segment of colon under study. He particularly favored the right and left lateral positions, with the rays directed horizontally, parallel with the floor, and the film held vertically, and he evolved an elaborate analysis of the various fluid levels and mural contours.

Fig. 7.—So-called spot film made with a fluororadiographic switch, under fluoroscopic control, without interruption of the fluoroscopic examination. Fine detail is recorded, as in this case of carcinoma of the descending colon.

The next stage of technical progress in colonic investigations with the roentgen rays was the development of methods for showing the internal mucosal relief of the digestive organs (figs. 5, 6, 8 and 13). Akerlund, Berg, Chaoul, Schwarz, Frik, Gilbert and many others might be mentioned, all of them basing their studies on

and particularly for the discovery of small polypoid growths (fig. 13) and mucosal ulcerations.

Proper double contrast study for delineation of the mucosal pattern requires thorough preparatory cleansing of the colon to remove scybala, organic debris, mucus and the like. This is best accomplished by the administration for several days of liquid petrolatum, or by 25 or 30 Gm. of castor oil administered the night before, with ordinary cleansing enemas of tap water rendered slightly astringent with 1 per cent of tannic acid. These should be given warm, at low pressure, with the patient lying supine and with the enema tip inserted not more than an inch (2.5 cm.). The last cleansing enema should be terminated an hour or more, better three hours, before the attempt at x-ray study. The use of salines or other purgatives should be proscribed, for they provoke hyperemia and turgescence of the mucous membranes, as do also strong soap enemas, and lead to colonic spasticity and retention of the opaque enema, the expulsion of a goodly portion of which before the insufflation is so necessary to success. Such preparation is contraindicated in suspected acute inflammations, such as appendicitis, sigmoiditis or diverticulitis, in suspected acute obstruction and in advanced cachexia or impending syncope. The insufflation becomes an unsatisfactory method when the patient cannot expel the opaque enema. In marked atonicity of the colon, the use of a cold contrast enema enables the patient to make a better expulsion of opaque material preparatory to the insufflation.

I was called in consultation in two cases of colonic diverticula in which rupture of a diverticulum occurred during rectosigmoidoscopic manipulations, one of them an examination and one a treatment. In both cases an emergency operation was demanded as a life-saving measure. But in addition to gross rupture necessitating immediate laparotomy there is the somewhat greater likelihood of the passage of air through small openings in diverticula with subsequent infection of the peri-

Fig. 8.—Case illustrating the value of patience and deliberation in x-ray study of the colon. The patient presented an obstinate constipation with marked left-sided tenderness coinciding with a resistant area. At A one sees a filling defect in the sigmoid visualized with the ordinary opaque clyster. At B this stricture in the sigmoid is further shown by injection of air following partial evacuation of the opaque clyster. The diagnosis as to whether the stricture is malignant or benign is still in doubt. By reinjecting some opaque material and waiting five or six hours (C) the presence of multiple diverticula is recognized, and the diagnosis of diverticular tumor is clear.

the original work of Forssell. In this country Weber, Gershon-Cohen and others have led in reestablishing interest in air injections of the colon following the barium sulfate enema and have brought the "combined method" or "double contrast method" to a high state of refinement in technic and interpretation in the search for some means of making an earlier diagnosis of carcinoma of the colon, in differentiating various types of colitis

toneum. Overdistention with the opaque enema may also be somewhat hazardous for the same reason.

There are also the cases in which insufficiency of the anal sphincter inhibits the use of either the barium sulfate enema or the insufflation of air. In such, the oral use of umbrathor or of some similar preparation is likely to give some help. Schwarz has described a method of introducing the contrast enema through a

rectal tube surrounded by a cotton pack and held in place by adhesive plaster.

In daily practice it transpires that the examination of the colon usually begins with the contrast enema. The patient is in the supine position, with the tip inserted only an inch or so within the sphincters. The examiner's eyes are duly prepared for roentgenoscopy. Cassettes are ready at hand and the controls are so

Fig. 9.—Annular carcinoma of rectosigmoid associated with diverticula of the sigmoid. Resection of the tumor required removal of a portion of the fundus of the bladder and the sigmoid to a point above the obstruction, with end-to-end anastomosis.

arranged that immediate x-ray films may be made without loss of time or interruption of the screen study should something be noted worthy of record. The flow is started and careful scrutiny of the lower part of the rectum and anal region is begun the moment it commences to visualize. Occasionally at the moment of

Fig. 10.—This case illustrates the necessity of having a physician-radiologist conduct the entire examination of the colon by enema under fluoroscopic control. In this case a definite filling defect is seen in the rectum before it becomes completely filled with the opaque enema; for with complete distention with the opaque enema the defect due to the carcinoma is entirely hidden by overlying shadows.

beginning the opaque injection a small anal lesion (fig. 10) can be detected which is soon overshadowed by the rectal mass.

As the opaque column begins to ascend the sigmoid, the patient is partially turned on one side, usually the left, so that every inch of the advancing colonic shadow may be studied. Palpation is employed as needed. Care is taken to avoid confusion of small gas or air pockets

in one of the colonic haustra (fig. 4) with a polypoid growth. In spite of all precautions, small rounded fecal residues may lead to similar confusion. Serious error may result from failure to recognize these possibilities. Straight lateral films with the patient turned completely on the left side sometimes bring out small defects in the rectal shadow from intrinsic disease or from extension of disease from the prostate, bladder or other genito-urinary organ.

These observations completed, the patient is turned once more on the back and the progress of the opaque enema further observed. Too much haste must be avoided. A relatively small amount of contrast material will suffice to visualize the entire colon without overdistending it if one is not too precipitate. Impatience and press of work are incompatible with successful fluororadiography of the colon, especially if one wishes to combine contrast methods. Overdistention must be avoided if it is desired that the patient shall be able to make a satisfactory expulsion of the contrast fluid preparatory to the possible use of insufflation.

Again the patient is turned as needed to bring into unobstructed screen vision the two legs of the splenic and hepatic flexures. Intestinal coils may be pushed aside by palpation through the abdominal wall with the protected hand or the nonopaque wooden palpator.

Finally attention is given to the cecum. If the colon is of the irritable spastic type, the head of the opaque

Fig. 11.—It is necessary as a routine practice to make an oblique film of the sigmoid in all colonic examinations (B) as well as a film in the usual (A) anteroposterior or postero-anterior projection. In this instance the diverticula would have escaped detection had not the oblique observation been employed.

column will have reached the cecum quickly, and in most cases several feet of ileum will fill. Marked insufficiency of the ileocecal valve is one of the roentgenologic characteristics of the irritable colon, as was shown by Guido Holzkecht and Singer in Vienna twenty-five years ago. In cases of suspected ileocecal tuberculosis this filling of the ileum is helpful, permitting scrutiny of the terminal coils of ileum for possible ulceration. It is also helpful in granulomatous ileitis. But when it is desired to make insufflation studies after expulsion of the contrast enema, this filling of the terminal ileum by the opaque enema constitutes a distinct complication.

More satisfactory study of the cecum and ascending colon is possible if the patient is allowed first to expel part of the contrast enema, the object being to clear the rectum and sigmoid and to diminish the amount of opaque material in the rest of the colon distal to the hepatic flexure. This is particularly required when the cecum is elongated so that it extends into the true pelvis or when the sigmoid loop turns to the right. With the protected hand or palpator the cecum may be moved about to test its mobility and to make compression for the purpose of bringing out small defects on the anterior or posterior walls. This maneuver also insures complete filling of the cecum and ascending colon and

thorough admixture of the opaque material with any residual nonopaque residues. With such palpation and compression it is possible to detect even small ulcerations, polypi and diverticula on the anterior or posterior walls which might otherwise escape recognition. Compression may also be accomplished by interposing a loofah pad and making pressure with it by pushing on

Fig. 12.—Diverticulitis of the sigmoid completely hidden in the usual anteroposterior or postero-anterior film (A) but nicely visualized in the oblique projection (B). The differentiation between carcinoma and diverticulitis was based on the difference in caliber of the sigmoid at the site of the lesion (B) following the administration of antispasmodics (C). At operation the surgeon was undecided as to the diagnosis and did a colostomy. Five years later the patient is still in excellent health and the colostomy is still not closed.

the screen. These devices together with appropriate turning of the patient usually permit satisfactory study of the cecum, appendix and terminal ileum. The cecal region is perhaps the least satisfactory of all segments of the colon for study with insufflation because of the confusing shadows resulting from air-filled coils of terminal small bowel, and it is here that the single contrast enema least needs supplementing.

Sometimes the patient expels the enema so completely that it is necessary to make a supplementary injection and partial expulsion before proceeding with the insufflation; but usually the difficulty is that the colon is insufficiently clear of the opaque fluid or that a satisfactory coating of the mucosa is not achieved. It is sometimes best to wait a little while, ten or fifteen minutes, before asking the patient to evacuate, and then he should be advised not to attempt too thorough expulsion of the contrast enema. It is better to evacuate too little and be sent back several times. Too violent expulsive efforts are likely to eliminate the mucosal coating completely. At once, after the proper degree of evacuation, as noted on the screen, has been achieved, another film or two may be exposed and the insufflation made. If the evacuation is still insufficient, the patient may be given a drink of ice water or an injection of double strength solution of posterior pituitary or of pitressin.

It will be apparent to those not personally familiar with the double contrast method that it is very much a time-consuming proposition, and in a busy office it can be employed only when there seems definite indication for it. Simply to inflate every colon after the routine contrast enema and evacuation will result in a high percentage of useless effort; for the resulting films, even though stereoscopic as they should always be, will hardly lend themselves to accurate interpretation unless they have been made with screen guidance as to position and moment of exposure. At best, many of the insufflation films are disappointing. Even when apparent polypoid growths are noted, the examination needs repetition before conclusions are drawn, unless it is possible in the primary examination to turn the patient in such favorable positions and, at time-consuming intervals, to differentiate between polypi, small gas bubbles and retained scybala.

There is another diagnostic pitfall in relation to polypi; viz., small boluses of gas in the third row of haustra (fig. 4). Ordinarily in the flat film one sees only two rows of haustral sacculations, since most of our studies are made with opaque or relatively opaque contrast mediums and without stereoscopic films. But the longitudinal bands of the colon and the haustral contractions form three rows of sacculations, the third one of which tends to accumulate small quantities of air or gas which, by being superimposed on the other shadows, may simulate polypi.

Still another device may aid in recognizing small intraluminal tumors, provided they exceed a centimeter or so in diameter; viz., observation of the contracted colon following expulsion of the contrast enema. This may show a localized fusiform enlargement of the bowel representing the localized bulging of the visualized mucosa where the colonic walls are propped apart by the nonopaque and otherwise invisible tumor mass (figs. 5 and 6).

The mucosal pattern method is also of value in selected cases. Sometimes the mucosal pattern is nicely exhibited spontaneously during the single contrast method or after partial expulsion or after insufflation. For artificial demonstration of the internal relief of the bowel without insufflation, the same special pains must be taken to cleanse the colon as with the preceding methods; then one injects slowly and without overdistention the opaque material (colloidal thorium or other agent selected), after which compression is made and

Fig. 13.—An air injection of the colon after expulsion of the opaque clysis (the combined method, so called), is sometimes valuable in showing up polypi. The definite diagnosis of polypi should not be made even in such a case as this without duplicating the result at another examination by similar technic.

maintained at suspected sites while Potter-Bucky diaphragm films are made for record and further study. Such films are preferably stereoscopic.

The inconvenience of the artificial mucosal relief method is probably out of proportion to its practical importance. To those who are especially devoted to this method, Schwarz remarks that the expensive

umbrathor has an astringent content which probably explains its usefulness. If an ordinary contrast enema is rendered slightly astringent by the addition of 1 per cent tannic acid it seems to answer the purpose equally well at a fraction of the cost. Especially in cancer it has not yet been shown that the demonstration of the mucosal pattern aids materially in the diagnosis. The presence of an intact mucosal relief pattern does not exclude carcinoma, for in some cases, especially the early ones which it is so desirable to recognize, the lesion may make a considerable submucous extension before breaking through the mucosa. More important than the mucosal relief pattern is the constant finding of a circumscribed narrowing of the lumen or encroachment into the lumen, and a delineation of the exact contours of the afferent and efferent stretches of mucosa in the vicinity of the defect. The mucosal pattern method depends chiefly on one's success in coating with the opaque materials the wall of the colon so well that the lateral contours of the mucosal lining are traceable as accurately as though drawn in with a sharp pencil.

Clinical Notes, Suggestions and New Instruments

THE PRIMARY CUTANEOUS TUBERCULOSIS COMPLEX

HERRERT K. FIDLER, M.D., UNIVERSITY, ALA.

The importance of differentiating between the lesion found in first infection tuberculosis and that resulting from reinfection was recognized first by Ghon¹ in 1912. Since then it has been customary to think of the primary tuberculous lesion, found most frequently in childhood, as confined chiefly to the lung, because most of his cases were of this type. This is probably true; but if the site of initial entrance of the tubercle bacillus is through the skin the resulting lesion differs from the well recognized types of adult skin tuberculosis (*verruca necrogenica*, *lupus vulgaris* and *tuberculosis colliquativa*) in a manner similar to that in which the childhood pulmonary lesion differs from the adult pulmonary lesion. This concept is not new, as Ghon in his original communication reported one case of primary skin tuberculosis as well as several cases in which the site of entry had been the tonsil or bowel. Until recently, however, there has been little attempt to differentiate between the rather characteristic first infection lesion of the skin and that produced by reinfection.

The basis of our dermatologic knowledge of the primary cutaneous complex was laid in 1926 by Bruusgaard.² The literature was thoroughly reviewed by Krantz³ in 1931 and by Michelson⁴ in 1935.

Bruusgaard² gives the following definition: "The characteristic feature of infection occurring in a previously tubercle free organism is the so-called 'primary complex,' consisting of a primary tuberculous sore plus a definite and often very pronounced swelling of the regional glands. The spreading of the bacilli to the regional glands is frequently shown by a clearly marked lymphangitis. The dominating feature of this symptom complex is the great swelling of the glands, of acute onset, with caseation." The lesion is necessarily confined almost entirely to children, although authenticated adult cases have been reported. The lesion is initiated by some injury to the skin and usually commences as an ulcer with an associated

lymphangitis and lymphadenitis. The ulcer is usually small, the edges are raised and slightly undermined and the floor is dark red and covered with fine granulation tissue, from which there comes a thin yellow serous exudate. The surrounding skin is purplish red and indurated. Although it does not differ markedly from an indolent ulcer caused by a streptococcal or staphylococcal infection, it frequently resembles the primary lesion of syphilis, from which it derives the name "tuberculous chancre."

Unlike the reinfection type of skin tuberculosis, the lesion is accompanied by an acute lymphangitis and lymphadenitis similar to that which is found in the primary pulmonary lesion. In a few weeks the ulcer may heal while the regional lymph nodes continue to enlarge, soften and finally break down. Thus,

Section of skin removed from the thumb, showing a tuberculous lesion situated in the dermis. Three tubercles are seen, each consisting of a mass of epithelioid cells, lymphocytes and a few giant cells (X 140).

suppurating tuberculous glands in the groin may be explained by a hitherto unsuspected lesion hidden between the toes, as occurred in a case reported by Stokes.⁶ The ulcer may spread by the formation of small lupus-like nodules or, if the ulcer becomes epithelized, it may resemble a small patch of lupus vulgaris.

The diagnosis of the condition is based on the presence of a local ulcerated lesion accompanied by lymphatic involvement, on a previously negative tuberculin reaction which becomes positive and, finally, on biopsy and guinea-pig inoculation of the lesion or regional lymph nodes.

REPORT OF CASE

A white man, aged 25, was engaged on the staff of a tuberculosis sanatorium. In the course of his duties, which included autopsy examinations, there developed at the site of what was first thought to be a mosquito bite on the right thumb a small ulcerated lesion about 5 mm. in diameter. This was accompanied by a rise in temperature to 100.2 F. and an acute lymphangitis which extended from the lesion to the axilla.

5. Bruusgaard, E.: *The So-Called Primary Complex of Tuberculosis in the Skin*, *Brit. J. Dermat. & Syph.* 46:113 (March) 1934.

One of the axillary lymph nodes was enlarged to the size of a walnut and was moderately painful. The lesion on the thumb was slightly raised, red and indurated and from the ulcerated center a thin serosanguineous exudate could be expressed. Repeated darkfield examinations were negative for *Spirochaeta pallida* and preparations stained for acid-fast organisms were negative.

The lesion remained unchanged and lesser degrees of lymphangitis recurred intermittently for almost two months. The intradermal tuberculin reaction, taken three weeks after the onset of the illness, was strongly positive (four plus) with 0.1 cc. of 1:1,000 old tuberculin.

The possibility of this being a primary tuberculous infection was strongly entertained. Three years previously (1932) the intradermal tuberculin reaction had been negative to 0.1 cc. of 1:1,000 old tuberculin and roentgenograms of the chest revealed no evidence of tuberculosis. Since then the patient had been in good health and a routine chest plate taken in 1934 showed no pulmonary lesion.

Two months after the onset the ulcerated surface became epithelized but there remained a slightly firm, raised, reddish lesion with an irregular margin in which small "apple jelly" nodules about 1 mm. in diameter could be seen on diascopic examination. This lesion grew slowly until in January 1936 (six months after onset) it was 1 by 0.75 cm. The axillary lymph node became large and tender again, and the lymphatics in the arm and forearm became shortened, cordlike and easily palpable, though not tender, and made full extension at the elbow difficult.

At this time the primary lesion on the thumb was removed widely by the cutting cautery and a Thiersch graft from the thigh was applied. By the end of a week the lymphatics were no longer palpable and the axillary lymph node had receded in size.

Microscopic examination of the tissue removed revealed a lesion situated in the dermis and consisting of single and conglomerate foci containing epithelioid cells, lymphocytes and a few giant cells. In the center of some of these masses there was definite caseation. Acid fast organisms could not be found by histologic examination, guinea-pig inoculation or attempts at culturing on artificial mediums.

Three months later (April 1936) the axillary lymph node was removed. It measured 2 by 2 by 1 cm. The cut surfaces showed two pale yellow caseous regions which occupied about one half of the node. The capsule was indistinct and in places the surrounding fat seemed to be infiltrated. Direct smears from the caseous region showed acid fast rods corresponding in number to Gaffky II. Guinea-pig inoculation with this material resulted in the development of tuberculosis.

One year following the onset of the illness the intracutaneous tuberculin reaction was moderate (two plus) to 0.1 cc. of 1:10,000 old tuberculin. There was no demonstrable recurrence of the lesion on the thumb or in the axilla, and the general health of the patient was excellent.

COMMENT

It is difficult to believe that a man, aged 25, who had lived in a large city since childhood and had been engaged in hospital work for a period of four years, should not have had some previous tuberculous infection. The negative tuberculin reaction before the onset of illness indicated that he was not allergic to the organism, and that he had little resistance was evidenced by the acute ascending character of the lesion with no apparent effort to fix the organisms at the primary site. It is well known that after a childhood infection recovery may be followed years later by a loss of allergy. So far there has been little or no evidence to show that acquired resistance also vanishes. Rich and McCordock⁷ state that they have seen a few adult patients with pulmonary tuberculosis in whom the anatomic lesions and course resembled the primary infection. They suggest the possibility of this being the result of a fresh infection from without in an individual who, if ever having had resistance, has completely lost it. They continue to say, however, that the infrequency of reactivation of the remaining bacilli in the pulmonary and node lesions of the childhood "primary complex"

is strong evidence that resistance once acquired in childhood is rarely completely lost. Although the point is virtually impossible to prove, it seems quite possible that the case which is reported here is not a true first infection but has occurred in an individual who has lost any allergy and resistance that might have been produced by a previous infection, and that reinfection has resulted in a lesion identical with the "primary complex."

It is interesting to note the change in type of the lesion that took place as the patient was apparently developing resistance to the infection. The acute lymphangitis subsided and after two months the lesion on the thumb changed from an open ulcerated "tuberculous chancre" to a more localized productive type of lesion resembling a common type of adult reaction—*lupus vulgaris*.

SUMMARY

This case seems to fulfil all the prerequisites for a diagnosis of primary cutaneous tuberculosis complex in an adult. The onset was marked by an acute ulcerative lesion on the thumb with an accompanying lymphangitis and axillary lymphadenitis. The intradermal tuberculin reaction, which had previously been negative, became strongly positive. The histologic picture of the local lesion resembled tuberculosis, and the tubercle bacillus was obtained from the axillary lymph node.

COMPLETE COMPOUND DISLOCATION (INTERNAL LATERAL) OF THE ANKLE JOINT WITHOUT FRACTURE, WITH PRIMARY HEALING

H. EARLE CONWELL, M.D.
BIRMINGHAM, ALA.

AND
RUFUS HENRY ALLDREDGE, M.D.
NEW YORK

A complete dislocation, simple or compound, at the tibiotalar joint without a fracture is extremely rare.¹ A lesion of this type when it does occur is usually compound. The ligaments about the ankle are usually stronger than the malleoli, and for this reason a fracture of one or both of the malleoli usually

Fig. 1.—Complete compound dislocation (internal lateral) of the left ankle joint. Note that the lower tibiofibular articulation is intact.

accompanies such an injury, since the bone in most instances breaks before the ligaments will rupture.

Döhler² states that a lateral dislocation of the ankle without a fracture of one or both of the malleoli is possible only when the joint between the tibia and the fibula is broken. In the case reported here a separation did not occur at the tibiofibular joint, as shown by roentgenograms and by open inspection of the joint.

Complete dislocations of the ankle joint are classified as follows, according to their order of frequency: (a) posterior, (b) anterior, (c) external lateral, (d) internal lateral (medial) and (e) divergent or upward.

From the Orthopaedic Clinic of the Employees' Hospital, Fairfield, Ala.

1. Key, J. A., and Conwell, H. E.: *Management of Fractures, Dislocations and Sprains*, St. Louis, C. V. Mosby Company, 1934.

2. Böhler, Lorenz: *Treatment of Fractures*, fourth English edition translated by E. W. Hey Groves, Baltimore, William Wood & Co., 1935.

7. Rich, A. R., and McCordock, H. A.: *An Inquiry Concerning the Role of Allergy, Immunity and Other Factors of Importance in the Pathogenesis of Human Tuberculosis*, Bull. Johns Hopkins Hosp. 44: 273 (May) 1929.

The case here reported is of interest because:

1. It is a rare lesion, the only one of its type we have seen.
2. It definitely proves that ligaments about a major joint do rupture in certain instances without pulling away the bone or periosteum to which they are attached.
3. There was no associated fracture.
4. The wound healed without infection.
5. The end result was excellent.

REPORT OF CASE

R. L. C., a railroad engineer, was admitted to the Employees' Hospital March 7, 1936, shortly after he had been in a railroad accident in which he received a serious injury to the left ankle and multiple steam burns to the lower extremities.

Examination on admission revealed a complete compound medial dislocation of the left ankle joint. The wound was very dirty, and particles of coal were ground into the tissues. The lower articular surfaces of the tibia and fibula were plainly visible, protruding from the wound (fig. 1). The foot was cyanotic and cold. Pulsations in the vessels of the foot were absent. The patient also had second degree burns about both ankles and on the right leg and back.

A roentgenogram was made which revealed a complete medial dislocation at the tibiotalar joint, with no associated fracture (fig. 2).

Operation was performed under general anesthesia. The wound was thoroughly cleansed and débridement was performed. The dislocation was reduced simply by traction on the foot and countertraction on the flexed leg. The ligaments on the open side of the ankle were reapposed and sutured with

Fig. 2.—Anatomic deformity with no fracture present.

interrupted chromic catgut. The skin was sutured with silk-worm gut and a small rubber drain was placed in the wound. This was removed forty-eight hours later.

Owing to the fact that the patient had a second degree burn over the ankle, a Steinmann pin was applied through the os calcis and traction used, reduction being maintained thereby. A gauze dressing was kept on the wound, which was inspected daily until healing of the compound wound and most of the acuteness of the burns had subsided. It was desirable that a plaster cast be applied as soon as possible in order to relieve undue stretching of the torn ligaments about the ankle joint as the result of the traction. A cast was therefore applied about two weeks following injury, when the burns had improved sufficiently to warrant the application of it. The cast extended from the base of the toes to the upper third of the thigh. The Steinmann pin was then removed from the os calcis. A good sized window was cut away over the compound wound, which

had healed within about three weeks following injury as well as the burns.

The original cast was removed one month following its application, at which time another cast was applied to the foot and leg, extending from the base of the toes to the upper third of the leg. This cast was removed two weeks later. The patient was then fitted with a brace attached to the shoe heel, with a joint at the ankle. He began walking with this support and was discharged from the hospital to continue active weight bearing without the aid of crutches.

He was last seen in the orthopedic out clinic June 5, 1936, when he was walking without pain or discomfort, except for a slight arch strain, which was relieved with a sponge rubber arch support. Roentgenograms showed the tibiotalar joint to be normal. The ankle was not swollen and there was full motion with normal stability (fig. 3). He returned to his original work without any disability. He was advised to wear the metal brace for another month following this examination.

A SIMPLE PLIABLE FINGER SPLINT

JOHN E. BURCH, M.D., MIAMI, FLA.
Senior Resident Intern, Jackson Memorial Hospital

During the course of my intern service at Charity Hospital, New Orleans, I came in contact with numerous infections and disorders of the phalanges, both in the surgical wards and in

Fig. 1.—Detailed construction of splint.

the outpatient dispensaries. I found that, in treating these conditions, immobilization for a short period with the use of a simple finger splint in addition to the usual hypertonic wet dressings shortened the duration and intensity of symptoms and hastened the healing process.

I have done extensive reading among the numerous articles dealing with finger splints, and so far I find that the splint generally used in such conditions is the ordinary tongue depressor. After using this splint several times on miscellaneous infections about the finger tip, I noticed certain disadvantages:

1. The splint was hard and, if applied tightly, became painful to the patient after several hours.
2. It will not conform to a rounded surface, as it is not flexible.
3. It required padding.
4. It is very cumbersome to use on the hands of children.

Seeing the need for a simple splint that could be made with materials to be had in any physician's office, I finally devised what I think is a simple pliable finger splint. The splint consists of a parallel row of wooden applicators impinged on a layer of adhesive tape with a similar layer superimposed. A small margin is left on each side and folded over, making the splint water tight.

For my own use I have constructed two sets of splints, using one-inch and two-inch widths of adhesive tape. The one-inch splint may be used in infections of the finger tip, such as felons, paronychias and nail avulsions. In dealing with a felon it is advisable that the splint be applied to the volar surface of the finger, thus protecting the sensitive tip from trauma. In dealing with paronychias and nail avulsions the order is reversed, the splint being applied to the dorsal surface.

This splint can be used satisfactorily with wet dressings and need not be removed in order to soak the infected finger. The splint is water proof and does not become soggy or fall apart.

I also found that the one-inch splint could be used in simple phalangeal fractures without displacement of the fragments, when only immobilization is desired and traction is unnecessary. In using the full length one-inch splint in this manner, a satis-

Fig. 2.—One-inch anterior splint.

Fig. 3.—Lateral view showing anterior one-inch splint.

factory immobilization at the metacarpophalangeal joint is secured. When additional strength is desired, both an anterior and a posterior splint may be used, held securely in place with one-inch gauze bandage.

The two-inch splint is used for immobilizing the thumb and little finger, serving a double purpose both for immobilization and for abduction.

ADVANTAGES

1. The materials used in this splint are cheap and easily available.
2. It is slightly elastic and also molds to fit the curved surface of the finger.

Fig. 4.—Two-inch splint for abduction and immobilization of thumb.

Fig. 5.—Two-inch splint for immobilization and abduction of little finger.

3. The splint can be cut to the desired length with ordinary bandage shears, the cut edge being then covered with a small strip of adhesive tape.
4. It is light and neat and requires no padding.
5. It fits snugly and is easily held in place with one-inch gauze bandage.

THE MYXEDEMA HEART

WILLIAM H. ALLEN, M.D., FORT SAM HOUSTON, TEXAS

Since Zondek¹ first reported myxedema heart in 1918 there has been an increasing number of cases recorded. In 1925 Fahr² could find but eight cases with roentgenologic and electrocardiographic studies. At that time he described three cases that he had seen during the past year, one of which was reported in detail and two in outline. In 1932 he³ described the further progress of one of the preceding cases and reported five additional cases that he had seen in the preceding eight years. Of seventeen cases of severe and moderately severe myxedema, thirteen showed signs and symptoms of heart failure, of which five were severe.

Willius and Haines⁴ in 1925 referred to Fahr's first paper and reported a study of 162 cases of high grade myxedema

From the Medical Service of the Station Hospital, Fort Sam Houston, Texas.

Read before the Bexar County Medical Society, San Antonio, Texas, Nov. 5, 1936.

2. Fahr, George: *Myxedema Heart*, J. A. M. A. 84: 345-349 (Jan. 31) 1925.

3. Fahr, George: *Myxedema Heart*, Am. Heart J. 8: 91-101 (Oct.) 1932.

4. Willius, F. A., and Haines, S. F.: *The Status of the Heart in Myxedema*, Am. Heart J. 1: 67-72 (Oct.) 1925.

without finding a single characteristic case of myxedema heart. One hundred and forty-eight (91 per cent) were free of subjective or objective signs of organic cardiovascular disease; eleven (7 per cent) presented evidence of such organic disease but only one was appreciably influenced by thyroid therapy. However, in twelve cases the electrocardiographic changes disappeared after treatment with thyroid. Willius⁵ recently stated that there was little doubt that occasionally the syndrome is observed in myxedema and that the heart participates in the myxedematous process, but he objects to the term "myxedema heart" on the ground that there has been no necropsy report of an authentic case. Excellent reviews of the literature with added cases have recently been reported by Lerman, Clark and Means,⁶ and by Ohler and Abramson.⁷

The characteristic features have been a marked increase in the transverse diameter of the heart, feeble pulsations as viewed

cardiogram made. The patient was discharged March 23, 1935, on her own request.

May 7 she was admitted to the medical service, complaining of marked weakness, persistent diarrhea, with burning pain in the epigastrium, dermatitis on the hands, wrists and elbows, and numbness of both hands. Examination showed marked

Fig. 1.—Electrocardiogram of June 17, 1934, before administration of thyroid. Basal metabolic rate —38 per cent.

by the fluoroscope, and low amplitude of complexes with flattening of the P waves and with low or inverted T waves. Abnormal axis deviation has also commonly occurred.

Shortness of breath is a common complaint and a few patients have precordial pain. Moderate to severe anemia of the hypochromic type and uterine hemorrhages have been frequently reported. A number of the cases have shown elevation of blood pressure, though these have usually been associated with

arteriosclerosis or a history of preexisting hypertension. The changes in blood pressure following treatment have been variable.

REPORT OF CASE

Mrs. R. L. W., a married woman, aged 42, was first admitted to the surgical service March 7, 1934, with a history of persistent uterine hemorrhage of two months' duration. The uterus was moderately large and it was thought that there was possibly an intramural fibroid tumor. Blood count showed hemoglobin 30 per cent, red blood cells

Fig. 2.—Teleoroentgenographic study, Aug. 4, 1934. Transverse diameter of heart 18.5 cm.; of chest 26 cm.

2,240,000, white blood cells 6,700, differential count normal. The Kahn and Wassermann tests were negative.

The patient received a transfusion of 260 cc. of whole blood. An exploratory laparotomy was refused. On this admission there is no notation of cardiac abnormality, nor was an electro-

pallor and the dermatitis already noted. The pulse was of poor volume and the blood pressure 84 systolic, 70 diastolic. The heart showed a marked increase in the transverse diameter. The sounds were weak and distant. The rhythm was regular. No murmurs were heard. There was tenderness over the whole abdomen, with some ascites and hydrothorax. The blood count revealed hemoglobin 30 per cent, red blood cells 2,200,000, white blood cells 2,350, differential normal. Examination of the urine and feces was negative. Gastric analysis showed absence of free hydrochloric acid.

Blood sugar was 90 mg. and nonprotein nitrogen 30 mg. per hundred cubic centimeters. A tentative diagnosis of pellagra and severe hypochromic anemia was made because of this and uterine hemorrhages. She was placed on a high vitamin diet, supplemented by brewers' yeast and viosterol. Iron and ammonium citrate 1 Gm. three times a day and intramuscular injections of liver extract and digitalis were also given. Roentgen treatment was administered over

Fig. 4.—Teleoroentgenographic study, May 17, 1935. Transverse diameter of heart 12 cm.; of chest 26 cm.

both ovaries and to the right hand, the left hand being used as a control. A blood transfusion of 250 cc. by the direct method was given on May 28, the blood count having remained essentially the same up to this time. No improvement followed the transfusion. June 17 an electrocardiogram showed low voltage complexes with flattened P and T waves and left axis deviation (fig. 1). The appearance of the electrocardiogram and the large size of the heart suggested myxedema. The basal metabolic rate was found to be —38 per cent. She was placed on thyroid, 130 mg. daily. Improvement in her condition was rapid. July 4 the hemoglobin was 55 per cent, red blood cells 2,930,000, white blood cells 12,200, with normal differential count. By July 10 the hemoglobin had increased to 65 per cent. The patient was discharged to the care of the outpatient service, July 13. The dermatitis had entirely cleared, no difference having been noticed in the rate of recovery in the two hands; the ascites and hydrothorax were gone, and there was a marked improvement in strength and mental outlook. August 4 the basal metabolic rate was —8 per cent. On this date a 2 meter film showed a total transverse diameter of the heart of 18.5 cm. with a transverse diameter of the chest of 26 cm. (fig. 2).

5. Willius, F. A.: Personal communication to the author.

6. Lerman, J.; Clark, R. J., and Means, J. H.: The Heart in Myxedema: Electrocardiograms and Roentgen-Ray Measurements Before and After Therapy. *Ann. Int. Med.* 6:1251-1271 (April) 1933; Further Observations on the Heart in Myxedema, *ibid.* 8:82-84 (July) 1934.

7. Ohler, W. R., and Abramson, Julius: The Heart in Myxedema. *Arch. Int. Med.* 53:165-187 (Feb.) 1934.

The patient left the city and was not heard from until her readmission to the surgical service March 24, 1935, at which time she gave a history of having discontinued treatment and of a sudden onset of profuse menorrhagia on March 8, which had continued up to the time of readmission. Her condition was critical. She was profoundly prostrated and partially disoriented. The uterine flow was free and serous, with very little color. Her pulse was 112; blood pressure 78 systolic, 40 diastolic. The heart sounds were distant. There was tenderness over the uterus, which was moderately enlarged and firm. The cervix was enlarged and a little softer than normal. Blood count was hemoglobin 25 per cent, red blood cells 1,070,000, white blood cells 14,800. She received transfusions of 300 cc. of whole blood by the direct method on the 25th and 30th. Following these the hemoglobin increased to 40 per cent and the red cells to 2,420,000. There was a marked increase in the transverse diameter of the heart, the apex being visible in the fifth interspace in the anterior axillary line (12 cm. from the midline); the sounds were of fair quality; no murmurs were heard. The lungs, abdomen and extremities were normal. She was again placed on liver extract intramuscularly, iron and ammonium citrate, and thyroid 130 mg. twice a day. April 5 an electrocardiogram showed rate 82, rhythm regular, auriculoventricular conduction time 0.16 second, and all complexes of low voltage but of greater amplitude than in the one of June 17, 1934. There was also a left axis deviation (fig. 3). April 8 the basal metabolic rate was -21 per cent; May 1 it

Fig. 5.—Electrocardiogram of May 17, 1935, after administration of thyroid. Basal metabolic rate -3 per cent.

was plus 9 per cent. On that date the hemoglobin was 75 per cent, red blood cells 3,980,000, and white blood cells 10,200; the blood pressure was 120 systolic, 84 diastolic. Supravaginal hysterectomy was performed under spinal anesthesia May 2. Sections showed an endometrioma of the left cornu. Surgical recovery was uneventful. A 2 meter film May 17 disclosed that the transverse diameter of the heart had decreased from 18.5 cm. to 12 cm. (fig. 4). An electrocardiogram showed increase in voltage with marked left axis deviation (fig. 5). The basal metabolic rate the same date was -3 per cent. She was discharged May 18. She was last seen July 2, 1936, at which time her condition was excellent. The transverse diameter of the heart was 12 cm., the sounds were clear, and there were no murmurs. The blood pressure was 120 systolic, 84 diastolic. She had been taking thyroid 32 mg. daily but no other treatment.

COMMENT

This case presents the cardinal features of the so-called myxedema heart, characterized by a marked increase in diameter, feeble pulsation, and electrocardiographic complexes of low voltage with flattened P and T waves. Marked decrease in size of the heart, improvement in function and change in the electrocardiogram followed treatment with thyroid. Whether hysterectomy was justified in view of the frequent occurrence of uterine hemorrhage in such cases is questionable. It was done in view of the critical condition of the patient and her failure to continue the thyroid treatment following her second discharge from the hospital. In this case it would appear that the source of the hemorrhage was the endometrioma. Whether the hypothyroidism was a factor is unknown, as is also the relationship of the pellagra-like lesions and symptoms.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

COLSON SAFETY INHALATOR, MODEL NH-11, ACCEPTABLE

Manufacturer: The Colson Corporation, Elyria, Ohio.

This device is recommended as an adjunct in the treatment of nasal or respiratory disturbances and for inhalations of vapor or medicated vapor as prescribed by the physician. The heating element, internal connections, and so on, are enclosed in the cabinet, size 20½ inches long and 8¼ inches wide over the handles. The height with the tube removed is 18½ inches. The power required is 500 watts and 115 volts. The flexible tube is 32 inches long and terminates with a nozzle 9 inches in length. It weighs 12 pounds empty. The steel cabinet is finished in ivory baked-on enamel. The interior parts in contact with the water or medicine are seamless copper, nickel plated.

The firm claims that this unit is an improvement over the former inhalator accepted by the Council and described in *THE JOURNAL*, May 26, 1934, page 1760.

If the water supply should become exhausted through an oversight, an automatic thermal switch cuts off the electric current, the red signal light glows and the reset switch is released. The inhalator cannot be put back in operation until it has been cooled to normal temperature by replenishment of the water supply. When the unit is set on "high heat" the water supply will last for approximately eight hours. If on low heat, the water supply continues for approximately sixteen hours. It is so arranged that a medicament cup may be placed directly over the rising steam, thus affording an opportunity for the volatilized medicine to mix with the steam.

The inhalator was investigated in a clinic acceptable to the Council. Its performance and operation were regarded as satisfactory.

In view of the favorable report, the Council on Physical Therapy voted to include the Colson-Safety Inhalator, Model NH-11, in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

NEO-IOPAX (See New and Nonofficial Remedies, 1936, p. 256).

The following dosage form has been accepted:

Ampoule Solution Neo-Iopax, 10 cc.: Each ampule contains neo-iopax, 7.5 Gm., dissolved in sufficient sterile distilled water to make 10 cc.

DEXTROSE (See New and Nonofficial Remedies, 1936, p. 289).

The following dosage forms have been accepted:

The Lakeside Laboratories, Inc., Milwaukee.

Ampoules Dextrose (d-Glucose) 5 Gm., 10 cc.: Each ampule contains dextrose (d-glucose) 5 Gm., in distilled water to make 10 cc.

Sterile Solution Dextrose (d-Glucose) in Rubber Stopped Vials 25 Gm., 50 cc.: Each ampule contains dextrose (d-glucose) 25 Gm., in distilled water to make 50 cc.

Sterile Solution Dextrose (d-Glucose) in Rubber Stopped Vials, 50 Gm., 100 cc.: Each ampule contains dextrose (d-glucose) 50 Gm., in distilled water to make 100 cc.

TETANUS TOXOID, ALUM PRECIPITATED (See THE JOURNAL, May 16, 1936, p. 1735; Revised Supplement to New and Nonofficial Remedies, 1936, p. 16).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Tetanus Toxoid, Alum Precipitated, Refined.—Marketed in packages of two 1 cc. vials (one immunization treatment); and in packages of one 10 cc. vial (five immunization treatments).

ANTIPNEUMOCOCCIC SERUM, TYPE II (See New and Nonofficial Remedies, 1936, p. 374).

The National Drug Co., Philadelphia.

Antipneumococcic Serum (Felton) Type II, Refined and Concentrated.—Prepared by immunizing horses with intravenous injections of virulent and avirulent pneumococci, and subcutaneous injections of the supernatant broth culture mediums in which the pneumococci had been grown. When test bleedings show the serum to have reached a sufficient degree of potency, the horses are bled aseptically and the serum is refined and concentrated by a method similar to that used for antitoxins. The potency of the product is determined and expressed in terms of the unit of Lloyd D. Felton. Marketed in packages containing 10,000 and 20,000 units of type II pneumococcus antibodies.

PHENOLSULFONPHTHALEIN (See New and Nonofficial Remedies, 1936, p. 194).

Phenolsulfonphthalein—"National."—A brand of phenolsulfonphthalein—U. S. P.

Manufactured by the National Aniline and Chemical Co., Inc., New York. No U. S. patent or trademark.

LIVER EXTRACT (INTRAMUSCULAR)-PARKE, DAVIS & CO. (See New and Nonofficial Remedies, 1936, p. 281).

The following dosage form has been accepted:

Solution Liver Extract (Intramuscular)—P. D. & Co., 10 cc. vials.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary.

THE NUTRITIONAL SIGNIFICANCE OF THE CURD TENSION OF MILK

I. The Production and Properties of "Soft Curd" Milks

Although milk ordinarily is considered a fluid, it clots soon after it reaches the stomach and should be thought of as a "solid food." The size and degree of toughness of the clots are considered by many authorities to be important factors in the gastric digestion of milk. The character of the milk curd has claimed the attention of pediatricians for many years. Human milk forms a soft, almost fluid, coagulum in the stomach, whereas untreated cow's milk tends to form compact, cheesy masses. Some of the curds formed from raw cow's milk, observed by Brennemann¹ in a subject who could voluntarily regurgitate, measured 4 or 5 inches in length; others were apparently too large to pass the throat and could be recovered only after the digestive processes had reduced their size. If the milk was first boiled, the curds formed were smaller and more friable and appeared to be more quickly digested. Since the time of Brennemann's pioneer experiments, laboratory methods have been devised for the quantitative determination of curd tension. Considerable information has been gathered on the effect of different processes on the nature of the curd. The purpose of the present report is to summarize the available information on the production and properties of milk of "low curd tension."

NATURAL SOFT CURD MILK

Most observations on soft curd milk have been made possible by the development of methods for the determination of curd tension. Hill's method² has been improved by Cole³ and by

Miller.⁴ Stated briefly, the method consists of coagulating the milk in a jar by a solution of pepsin and, usually, calcium chloride, and the force required to pull or push a horizontal knife blade through the curd is read on a spring balance. The curd tension thus is measured in terms of grams of force under standard conditions. Hill defines soft curd milk as milk having a curd tension of 20 Gm. or less, while some other investigators allow an upper limit of 33 Gm. Differences in coagulant and in size and design of knife produce noncomparable results.⁵ Such variations in definition and methods of determination may account for some of the conflicting reports of the properties of soft curd milk.

The curd tension of untreated cow's milk may be found as high as 200 Gm. Certain cows, however, produce milk that has a much lower curd tension. This milk is sometimes referred to as "natural" soft curd milk. The production of soft curd milk appears to be an individual peculiarity of certain cows, which has been observed to persist from one lactation period to the next.⁶ While extremes of curd tension have been observed in the milk of all breeds of cattle studied, the proportion of cows giving soft curd milk is higher in some breeds than in others.⁶ The following breeds are listed in the order of their decreasing importance as producers of soft curd milk: Holstein, Ayrshire, Guernsey and Jersey.⁷ Although curd tension is fairly constant from day to day, it is high at the beginning of the lactation period and usually higher or occasionally lower at the end of the period.⁸ Several investigators have observed higher curd tensions during the winter months, particularly in the very cold weather, than in the spring and summer.⁹ It is interesting to note that some types of subclinical mastitis in cows have been found to be associated with the production of abnormal milk of low curd tension.¹⁰

Natural soft curd milk has been found by several investigators to be low in total solids,⁶ solids-not-fat,¹¹ fat,¹² and protein,¹¹ especially casein.¹³ The difference in casein concentration of soft and hard curd milk has been said to account for the greater part of the variation in curd tension.¹⁴ The caseins of hard and soft curd milks have not been found to differ in iso-electric point or amino acid makeup.¹⁵ In soft curd milk, calcium and phosphorus are present in normal ratio but smaller amounts;³ total ash has been reported normal¹⁶ and low.⁵ Natural soft curd milk in general is less concentrated milk; its lower caloric value has been confirmed by clinical experience.¹⁷ Buffer capacity, which depends largely on casein and phosphate, and titratable acidity, are low in soft curd milk.¹¹ Curd tension does not appear to be related to any of the following characteristics: lactose concentration,¹⁵ pH ,¹⁸ rate of rennin coagulation,^{6b} bacterial flora,^{6b} freezing point¹² or surface tension.⁵ According to several investigators the casein content is the sole or principal difference between naturally hard and soft

curd milks.¹⁹ Determinations of conductivity and viscosity carried out by Weisberg, Johnson and McCollum¹² indicate, however, that "the suspensoid phase differentiates a soft curd milk from a hard curd milk," that the fat, casein and calcium phosphate, by their concentration and manner of dispersion, control the curd character. This relationship may be explained in terms of coagulating centers, the number of which is affected by concentration of casein and interruption of micelles by fat globules. Another explanation is the adsorption of casein at the surface of the fat globules. The effectiveness of certain processes which reduce curd tension lends some support to the view of Weisberg, Johnson and McCollum of the factors that control curd tension in untreated milk.

MODIFICATION OF CURD BY VARIOUS TREATMENTS

Common methods of treating milk for infant feeding, such as dilution, heat treatment, homogenization, addition of acids or alkalis, removal of calcium, and the addition of cereal waters, all have in common the effect of reducing the curd tension of milk. Whether or not the product will have a curd tension of 30 Gm. or less depends on the initial curd tension and the kind and degree of treatment.

Dilution.—Dilution with water or whey has been found to lower curd tension to a degree not strictly proportional to the reduction of casein content.²⁰

Heat.—The result of heat treatment depends on the temperature and duration of heating. Pasteurization ordinarily has a negligible effect.²¹ While heating to 160 F. causes little change, a temperature of 180 F. reduces the curd tension according to the time of heating.²² Boiling for five minutes causes marked attenuation of the curd.²³ The heat treatment involved in the production of evaporated, sweetened condensed and powdered milks probably assures a soft curd in these products, though variations in curd texture have been noted.²⁴ The effect of heat on curd tension is thought to be due to partial denaturation of the proteins.²⁵

Homogenization.—Homogenization can be produced by forcing milk through minute openings under high pressure. The fat is finely divided by this process, remains suspended uniformly throughout the milk and does not form a cream layer. The softness of the curd of homogenized milk bears out the view of Weisberg, Johnson and McCollum¹² that the state of dispersion of the fat and casein is an important factor in determining curd character. About 2 per cent of the casein normally is adsorbed on the surface of the fat globules, but after homogenization 25 per cent is so held,²⁶ owing to the greater surface offered by the smaller fat globules. In line with Weisberg's view, it has been found that skim milk shows no change in curd tension when passed through a homogenizer,⁵ presumably because its fat content is too low to afford significant increase in surface. Evidence of theoretical interest is the effect of intense sonic vibrations in reducing curd tension.²⁷ Sound waves passing through milk, from one electrical plate to another, cause a dispersion of fat and increased surface for casein adsorption similar to that effected by homogenization.

The conditions of homogenization that determine the degree to which curd tension is lowered are initial curd tension, and temperature and pressure of processing. The higher the initial curd tension, the greater is its reduction by homogenization.²⁸ A processing temperature of 165 F. has been found to be more

effective in lowering the tension of the curd than 120 or 145 F.,²⁹ but probably the most effective method involves preheating to 180 F. followed by cooling to 100 F. and homogenization at the latter temperature.⁵ Increased pressure of homogenization up to 2,000 or 3,000 pounds per square inch increases the effect on curd tension,²⁸ but there is said to be little practical value in the use of pressures above 2,500 pounds per square inch.²⁹ A second processing does not further affect the character of the curd, which is fixed permanently by one treatment.²⁹

The study of the effect of these physical methods of treating milk demonstrates the importance of the conditions of treatment. The fact that milk has been heated or homogenized is no assurance that it falls within the soft curd range unless the initial curd tension and conditions of processing are known to be suitable. Thus, while evaporated, condensed and powdered milks usually have soft curds, "homogenized" or "heated" milks may show a higher curd tension.

Other Methods.—Modification by chemical means such as the addition of acids or alkalis and the removal of soluble calcium has been more or less widely used. The addition of either acids or alkalis reduces curd tension. The removal of calcium ions may be effected by the addition of citrate as part of the feeding formula, or by commercial treatment of acidified milk with one of the zeolites which gives up sodium or potassium in exchange for calcium. The zeolite or base-exchange method removes some of the phosphorus and about 20 per cent of the total calcium of the milk and is supposed to prevent coagulation in the stomach.³⁰ Such milk would not form a clot with rennin. However, evidence for the curd character of milk treated by base exchange is too slight to justify definite conclusions. Claims for the unimpaired nutritive value of this product despite its lower calcium content are based on a study of the calcium balance of one infant.³¹ Cereal waters, by virtue of their starch content, inhibit the formation of large curds,³² perhaps because the colloidal film formed on the surface of the curds prevents the coalescence of small curds into large ones.³³ Gelatin, however, appears to have little effect on curd texture but the evidence is somewhat conflicting.³⁴ Sugars have been found not to affect the curd.³² Milk coagulated with rennin and shaken to form a smooth, slightly thickened liquid has been observed to form soft curds in the stomach.³²

SUMMARY

Interest in the character of the curds formed by milk in the stomach has led to the development of laboratory methods for the quantitative measurement of curd tension. There is unfortunately no precise and generally accepted definition of what standards a milk must attain before it merits the designation of "soft curd." Large individual differences in curd tension may be observed in untreated milk from different cows. Natural soft curd milk appears to be a less concentrated milk, having a relatively low content of fat, casein and calcium phosphate. Pasteurization of milk has little effect on the nature of the curd, but softening of the curd may be accomplished by a great variety of methods. These include simple modifications used in the preparation of many infant feeding mixtures, for example, boiling (and it is the opinion of the Council that all cow's milk used for the preparation of infant feeding mixtures should be boiled), dilution, addition of acids or alkalis and the addition of various cereal waters. Removal of ionizable calcium is said to effect the softening of the curd. Homogenization of whole milk usually lowers the curd tension. Commercial methods of preserving milk involving evaporation or drying likewise usually yield a product that exhibits a low curd tension.

CHOLESTEROSIS OF THE GALLBLADDER

Virchow in 1857 described a peculiar stippled appearance of the mucosa of some gallbladders removed during necropsies. He regarded the yellow flecks and strands as fatty infiltration and suggested that the material is a neutral fat excreted by the liver and reabsorbed from the bile by the epithelial cells of the gallbladder mucosa. The condition received scanty attention from surgeons and pathologists, despite its not infrequent occurrence and a striking gross appearance.

Aschoff¹ demonstrated in 1906 the occurrence of cholesterol in the epithelial cells of the mucous membrane of the gallbladder. Moynihan² in 1909 presented an excellent description of the naked eye appearance of cholesterosis, calling attention to the yellow stippling of the mucosa. He regarded the discoloration as the result of an inflammatory process in which the epithelium was desquamated and the underlying tissue became bile stained. In six of his cases of this type, relief from symptoms followed the removal of the gallbladder; he pronounced the condition therefore a pathologic one requiring cholecystectomy. MacCarty in 1910 coined the descriptive name "strawberry gallbladder," which received universal adoption.

The term "cholesterosis of the gallbladder," suggested by Mentzer, more nearly describes the essential pathologic and clinical features of the condition. Boyd³ in 1923 found that the cholesterol content of the normal gallbladder wall was from 0.5 to 1.7 per cent of the dry weight, that of an inflamed gallbladder not the seat of cholesterosis 0.36 per cent, and that of a strawberry gallbladder from 34.6 to 60.5 per cent. He demonstrated that the fatty infiltrating material consisted of cholesterol esters. Policard and Illingworth likewise determined with the aid of the polarizing microscope, microchemical reactions and differential stains that the deposits of material in the epithelial layer of the gallbladder mucosa in cases of cholesterosis consisted

mainly of the esters of cholesterol. The subsequent investigations of Mentzer and others demonstrated that some degree of lipoid infiltration was a rather common condition in all gallbladders. Illingworth and Boyd have determined that typical cholesterosis of the gallbladder is accompanied in the majority of the cases by mild inflammatory changes. Most of the strawberry gallbladders removed at operation exhibited signs of inflammation, but this is not necessarily an argument in favor of an inflammatory genesis for the condition. Cases requiring surgical relief would naturally be those complicated by inflammatory phenomena. The discovery at operation or necropsy, however, of even a few cases of cholesterosis without a trace of inflammation might constitute a more weighty argument in favor of its essential noninflammatory character. The fact that about half of the cases of cholesterosis are associated with gallstones and that these are invariably of the cholesterol-rich type suggests the important part played by cholesterol in the formation of gallstones.

Bristowe⁴ in a paper published in 1887 recorded a case "in which there was a contracted gallbladder with extremely thick walls. Imbedded in these walls were a considerable number of cavities varying between the size of a pea and that of a bean, which were evidently mucous crypts. And within each one there were large crystals of pure cholesterine." He expressed the belief that "the bulk of cholesterine in gallbladder stones is derived not from the bile, but from the secretions discharged from the mucous surface." Naunyn⁵ emphasized the predominant rôle of cholesterol in the formation of gallstones. Cholesterol, normal constituent of the gallbladder bile of man and many mammals, is held in solution by the bile salts and the fatty acids. Cholesterol contained in the epithelial cells of the mucous membrane of the gallbladder is released through the physiologic process of shedding and breaking down normally taking place in the gallbladder. This process is greatly accelerated in inflammatory states of the mucosa. Thus, inflammation becomes the important factor in the genesis of the stones.

Naunyn⁶ in 1921 described cases in which the gallbladder mucosa was streaked with incrustated cholesterol flecks, while small cholesterol stones, the larger of which presented crystalline formation, were to be seen on the surface. Naunyn expressed his conviction that these structures developing in the mucosa derived their cholesterol from the latter and not from the bile. Lichtwitz suggested that the multiple mulberry stones commonly associated with cholesterosis had their origin in detached cholesterol polyps.

Opposed to the infectious theory of Naunyn are the views of Aschoff and Bacmeister.⁷ These investigators

maintain that cholesterol is absorbed from the gallbladder bile by the epithelial cells of the gallbladder mucosa and not secreted by them, that the process is essentially aseptic and that it is brought about by concentration of the gallbladder bile as a result of stasis and alterations in cholesterol metabolism. Bile stasis leads to absorption by the epithelial cells of the neutral fats of the bile, which normally hold the cholesterol in solution. As a result the cholesterol is precipitated out and leads to the formation of stones. Aschoff's demonstration of the purely metabolic aseptic nature of the formation of the solitary cholesterol stone has been generally accepted. Aschoff demonstrated in animal experiments that lipoids are being absorbed by the gallbladder wall. He introduced olive oil, butter and sterile milk into the gallbladder of dogs, the cystic duct being ligated, and was able to demonstrate the presence of lipid deposits in the gallbladder wall in all the animals. Illingworth⁸ demonstrated that cholesterol, when in excess, and in certain physical mixtures, can be absorbed by the gallbladder wall. He suggests that visible deposit of cholesterol in the gallbladder implies two processes: (1) absorption of cholesterol into the mucosa, depending probably on an increase in the cholesterol content of the bile, and (2) some change which unmasks this absorption of invisible cholesterol and prevents or delays its transport and leads to its accumulation on the mucous membrane. The part played by the inflammation consists, perhaps, of interfering with the absorptive processes, thus leading to accumulation of cholesterol in the gallbladder wall. Evidence of the opposite character is adduced by the experimental investigations of Elman and Graham.⁹ They state that, when the gallbladder was isolated by ligation of the cystic duct, the bile therein, after a sojourn of from two to sixteen days, contained a larger amount of cholesterol in all but one of nine experiments. Their conclusions are that the gallbladder does not absorb cholesterol, that it secretes cholesterol and that inflammation may accelerate the process.

Andrews, Dostal and Hrdina¹⁰ have urged that Elman and Graham's experiments are not convincing because of sources of error in their work. They call attention to the fact that the blood plasma of a dog contains much more cholesterol than the hepatic or cystic bile. Any exudation therefore of serum or introduction of a drop of blood from the needle puncture to obtain samples of bile would be sufficient, in their opinion, to vitiate the accuracy of these experiments.

Mackey,¹¹ in a recent histologic study of eighty-seven cases of cholesterosis, points out that the degree of cholesterosis was never proportional to the degree of the

inflammatory change and was rare if the latter was severe. He suggests that the etiology of cholesterosis is other than inflammation, since in not a few of his cases inflammation was entirely absent. The essentially aseptic nature of the solitary cholesterol calculus is, in his opinion, another argument against an inflammatory basis for cholesterosis. He concludes that cholesterosis and stones are not respectively cause and effect but are parallel results of supersaturation of the bile with cholesterol.

The preponderance of experimental proof seems to indicate that the gallbladder absorbs cholesterol from the bile and that cholesterosis is probably an infiltrative process. Infection, though frequently associated with cholesterosis, is not an essential factor and may be entirely absent. The relation of diet, of cholesterol metabolism, of cholesterolemia and of inflammation to cholesterosis and stone formation awaits further study.

PROTHROMBIN DEFICIENCY IN JAUNDICED PATIENTS

Few problems have so seriously concerned students of hepatic physiology as those concerned with the disturbed mechanisms of coagulation associated with jaundice or hepatic injury. Studies on the subject have been handicapped by preconceived ideas in regard to the effect of the constituents of regurgitated bile on the blood itself, but it is now apparent that the bile pigments, the bile salts or the cholesterol present in jaundiced blood have no particular effect on coagulation of blood and that some disturbance in hepatic function is the determining factor. Disturbances in coagulation of blood therefore must depend on a deficiency of some substance normally supplied by or stored in the liver or on some hypothetical anticoagulant derived from degenerating hepatic cells. The first hypothesis recently has been supported by new and valuable evidence.

The theory of blood coagulation now in general favor is that of Wöhlisch. According to this, a clot forms from the interaction of fibrinogen and thrombin, the latter substance in turn resulting from the combined action of prothrombin, thromboplastin, and calcium. Nygaard's¹ studies on coagulability of plasma of jaundiced patients seem to assign the cause of delayed coagulation in obstructive jaundice to a deficiency of prothrombin. Quick, Stanley-Brown and Bancroft² recently have determined prothrombin by a new method, employing an excess of thromboplastin and an optimal amount of calcium, leaving prothrombin as the only variable. These investigators find that the clotting time of recalcified plasma of jaundiced patients is greatly prolonged even after an excess of thromboplastin has been added; this indicates that the abnormality lies in a diminished

2. Quick, A. J.; Stanley-Brown, Margaret, and Bancroft, F. W.: A Study of the Coagulation Defect in Hemophilia and in Jaundice, *Am. J. M. Sc.* 190: 501 (Oct.) 1935.

quantity of prothrombin. The authors present additional arguments to support their views by showing that no other substance necessary for coagulation is deficient in jaundiced blood. Fibrinogen and serum calcium may be decreased in some instances, but fatal hemorrhage may occur even with normal levels of either substance. Thromboplastin, a cephaloprotein compound, is not lacking, as the studies of Quick, Stanley-Brown and Bancroft show, and certainly the thrombocytes from which it is derived are ordinarily present in normal numbers in jaundiced blood.

The correctness of the idea that deficiency of prothrombin is a cause of bleeding in hepatic disease is strongly supported by the recent observations of Hawkins and Brinkhous,³ who have shown that the hemorrhagic tendency in the presence of bile fistula of dogs is attributable to a low level of prothrombin in the plasma, a condition which may be corrected by feeding bile. They point out that normal blood contains a large excess of prothrombin, while only a small amount is necessary to normal clot formation, which may explain the temporary beneficial effect of blood transfusion.

There are other recent studies on prothrombin deficiency which have a direct bearing. In animals fed sweet clover hay which has been improperly cured, a hemorrhagic condition attributable to prothrombin deficiency results;⁴ a similar and probably a related condition can be produced in chicks by a diet deficient in the fat soluble vitamin K, and here again the prothrombin content of blood is reduced.⁵ Both conditions are prevented or relieved by feeding alfalfa hay or other substances rich in vitamin K. The similarity of the two conditions suggests that this vitamin and prothrombin may be related in some way, and Dam and his co-workers⁶ have strengthened this impression by demonstrating that prothrombin can be prepared from the plasma of normal chicks, while corresponding preparations from chicks lacking vitamin K are inactive.

As these investigators show, preparations of prothrombin contain vitamin K, a fact which is at variance with the observation that the vitamin does not act as prothrombin in vitro. No matter what the actual interpretations may be, it is apparent that both a toxic factor and a form of avitaminosis may have a similar effect on the prothrombin level of blood, and as Quick⁵ has noted, the latter condition may obtain in obstructive jaundice. The curative effects of feeding alfalfa may depend on the presence of vitamin K or on some accessory substance necessary for formation of prothrombin. An adaptation of these studies to an investigation of the hemorrhagic state in jaundice may conceivably lead to new light on an old and baffling problem.

ALLERGIC TISSUE CULTURES

The application of tissue culture methods has led to but few conclusions of greater clinical interest than the recent demonstration of the altered growth vigor of fixed tissue cells as a result of somatic sensitization to certain bacterial products. The first studies of the in vitro effects of specific bacterial antigens on tissue cultures were made about ten years ago by Rich and Lewis¹ of Johns Hopkins University. These investigators found that the addition of human type tuberculins to explants from the spleen of tuberculous guinea-pigs inhibited the growth and caused degeneration in these explants. The same tuberculins had no demonstrable toxic effects on explants from nontuberculous guinea-pigs.

This observation was adequately confirmed about four years later by Aronson² of the Phipps Institute at the University of Pennsylvania, who studied the allergic toxicity of tuberculins of avian, bovine and human type on explants from bone marrow, spleen and testes of both guinea-pigs and fowls. All these tuberculins were found to be toxic for explants from animals with homologous tuberculous infections. All were nontoxic on control explants from normal animals. Aronson was surprised to find that "tuberculin" from the so-called leprosy bacillus was toxic also for splenic explants from tuberculous fowls. Other acid-fast bacilli invariably yielded nontoxic "tuberculins."

The cellular nature of this tuberculous allergy, however, was not established by these earlier tests, since the explants were presumably saturated with humoral antibodies. Moen and Swift³ of the Rockefeller Institute, therefore, not only tested first generation explants from normal and tuberculous animals but made similar tests on second, third and later generation transplants from these tissue cultures. They report that tuberculin-sensitive tissues grown in normal culture mediums showed sensitivity to tuberculin through several transplantations, during which time many new generations of cells had developed. Of even greater clinical significance was their collateral observation that "the degree of cellular sensitivity to tuberculin does not parallel the acuity of the infective process . . . but represents a more or less permanent acquired characteristic impressed on the cell as a result of the infection."

Moen⁴ has recently extended his tissue culture studies to other bacterial antigens. He found that tissues isolated from guinea-pigs infected with group C hemolytic streptococci, for example, showed an acquired hypersusceptibility to extracts from hemolytic streptococci. This hypersusceptibility was shown by cellular degenerations and by inhibition of normal cellular growth and migration. Here also he found no correla-

tion between the degrees of sensitivity of splenic cells and the skin reactivity of intact animals. Neither the in vitro splenic allergy nor the independent cutaneous hypersensitivity is correlated with the specific antibody titer of the blood serum. The cellular sensitivity in streptococcal infections, however, is less permanent in character than the control tuberculin sensitivity. Second and third generation transplants are demonstrably less hypersensitive than the first generation explant.

Moen's results are in accord with the growing opinion that bacterial anaphylaxis is a harmful rather than a defensive tissue mechanism. Cells from infected animals display an increased vulnerability to the toxicity effects of homologous bacterial production. Moen emphasizes the fact, however, that this conclusion is not applicable to nonbacterial antigens. Tissue cultures from animals sensitized to horse serum, egg albumin or beef lens, for example, "are not specifically inhibited when the respective antigens are added to tissue cultures." A continuation of this promising line of investigation may in time give a new basis for the interpretation of many allergic and immune phenomena.

Current Comment

GIOVAN COSIMO BONOMO

On June 20 the two hundred and fiftieth anniversary of the discovery of the parasitic nature of scabies by Bonomo will be celebrated. This occasion has already received the attention of the American Association of the History of Medicine, which adopted and forwarded a resolution to the Italian Society of Dermatology and Syphilology and the Italian Society of the History of Medicine and Natural Sciences for their joint commemoration of "Scabies Day." According to Friedman, "it was not until 250 years ago that for the first time in history the etiology of any one of the diseases known to man was discovered."¹ That disease was scabies and, although the cause and effect were correctly assigned in 1687, it was not until 1834 that Bonomo's discovery was confirmed by Renucci, who demonstrated its true nature experimentally. Sharp-eyed peasant women, long familiar with the itch and its cutaneous habitat, had taught Bonomo just where to find the parasite and how to remove it. With clinical acumen Bonomo and his associate studied their patients. With the microscope they studied the organism and its habits. Bonomo, however, was guilty of at least two errors: first in saying that the acarid has six feet, whereas it has eight, and secondly in stating that the parasite can almost always be found in the "watery pustules" or vesicles, whereas actually it is never found within them. Nevertheless the clinical and logical proof of the parasitic nature of scabies was beyond doubt, in spite of these errors and in spite of the failure to attempt proof by experimental inoculation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Society News.—Reuben L. Kahn, Sc.D., director of clinical laboratories, University Hospital, Ann Arbor, Mich., addressed the Pima County Medical Society, recently, on "The Basis of Allergy in Man."

Appointments to State Health Department.—Dr. Alvy N. Crain, Phoenix, formerly director of the Maricopa County health unit, has been appointed director of local health administration of the state department of health, succeeding Dr. George A. Hays; Dr. Jack B. Eason, Yuma, has been placed in charge of the bureau of maternal and child health. Dr. Crain graduated at the University of Louisville School of Medicine in 1913. Dr. Eason graduated at Jefferson Medical College, Philadelphia, in 1930.

ARKANSAS

Forty-Two Years a Secretary.—Dr. Thomas Douglass, Ozark, was guest of honor at a banquet, May 4, in celebration of his many years' service as secretary of the Franklin County Medical Society. Dr. Douglass, who is 69 years of age, has served continuously for forty-three years, with the exception of the year 1922 when Dr. Edward W. Blackburn, Ozark, held the office.

Pediatricians Elect Officers.—Dr. Edwin C. McMullen, Pine Bluff, was elected president of the Arkansas State Pediatric Association at its annual meeting in Little Rock, April 12. Dr. Garland D. Murphy, El Dorado, was chosen vice president and Dr. Madeline A. M. Melson, Little Rock, was reelected secretary. The speakers at the session included Dr. Frank Thomas Mitchell, Memphis, Tenn., on "Diarrhea and the Present Status of Treatment."

Society News.—At a meeting of the Benton County Medical Society in Bentonville, April 8, the speakers, among others, were Drs. Joseph L. Johnston on "Treatment of Hay Fever" and Fred R. Farthing, Springfield, Mo., "Modern Treatment of Sterility."—A symposium on the recent advances in therapy was presented before the Sebastian County Medical Society April 20 by Drs. Arless A. Blair, Thomas P. Foltz and Frederick H. Krock. The program included a discussion of protamine insulin, hypertonic sucrose solution and prontosil. All the speakers are from Fort Smith.

COLORADO

Three Deaths from Botulism.—Three women died of botulism in Trinidad, April 24, according to the bulletin of the state board of health. One of the women served beans, canned by a member of the family, at noonday April 21 and next day the three victims complained of the same symptoms: headache, dizziness, ocular disturbances and weakness. They were admitted to the hospital, April 23, all having difficulty in breathing, swallowing and speaking. One died early Saturday morning, one in the afternoon and the third at 11 p. m. A 250 Gm. guinea-pig that had been injected with 2 cc. of juice from the same jar from which the beans were taken died in about five hours with typical symptoms of botulism.

CONNECTICUT

"Brilliant Health Leader" Fined.—"Dr. Howard V. H. Inches, Dynamic and Brilliant Health Leader of America and England," was recently fined \$25 and costs, following his plea of guilty to a violation of the itinerant vender law, according to the *New England Journal of Medicine*. Inches had begun a course on nutrition which, preceded by three free lectures, carried an entrance fee of \$10 per person. Forty-eight persons are said to have joined the class and each one received a seventy-eight page booklet on nutrition. On investigation no record was found of the organization said to be sponsoring "Dr." Inches. Columbia University reported that Inches had listened to a few lectures during one term and that he did not matriculate for credit, had passed no examination and was not qualified as an authority on nutrition. He offered for sale Orzone Powder and Orzoil. The price of each was \$1 and each was indispensable to the other. When Inches was arrested,

several diplomas were seized which were ready for presentation to the class on the completion of the course. The diploma was issued in the name of the American Dietetic Research Foundation, it was stated. Another diploma found in Inches' possession acknowledged him to be a graduate of the British College of Osteopathy. Subsequent investigation disclosed that this diploma had been issued Aug. 10, 1936, whereas the college was not registered as a business until September 2. One of Inches' companions was fined \$10 and costs.

FLORIDA

State Society Appoints Business Manager.—Stewart G. Thompson, Dr.P.H., has resigned as director of the bureau of vital statistics of the state board of health, Jacksonville, to become business manager of the Florida Medical Association on a full time basis, it is reported. Dr. Thompson has devoted part time to the position for many years.

Annual Short Course for Practitioners.—The fifth annual short course for physicians in Florida will be held at the Orange Court Hotel, Orlando, June 21-26, under the auspices of the state medical association and the University of Florida. The evening sessions will be devoted to symposiums on tuberculosis and neurosurgery. Speakers in the former will include Drs. Pol N. Coryllos, New York; Rollin D. Thompson, Orlando, and Thomas M. Palmer, Jacksonville, while the speakers in the second will include Drs. Claude C. Coleman, Richmond, Va., and James G. Lyerly, Jacksonville. Other participants in the course will include:

Dr. Walter L. Biering, Des Moines, health commissioner of Iowa, Medicine.
Dr. Jesse O. Arnold, professor of obstetrics, Temple University School of Medicine, Philadelphia, Obstetrics.
Dr. Alexander J. Schaffer, department of pediatrics, Johns Hopkins University School of Medicine, Baltimore, Pediatrics.
Dr. Bayard Carter, professor of obstetrics and gynecology, Duke University School of Medicine, Durham, N. C., Gynecology.
Dr. Ralph N. Greene, Coral Gables, medical director, Eastern Air Lines, Neuropsychiatry.
Dr. Wilbur E. Burnett, assistant professor of surgery at Temple, Surgery.

IDAHO

Annual Registration Due July 1.—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the Department of Law Enforcement and at that time to pay a fee of \$2. If a licentiate has not paid the annual registration fee by October 1, his license can be cancelled but will be restored within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been cancelled for more than five years, it can be reinstated only on the payment of \$25 and on the licentiate's passing an examination, the nature of which shall be determined by the Department of Law Enforcement.

ILLINOIS

State Tuberculosis Meeting.—The Illinois Tuberculosis Association held its annual meeting in Rockford, April 20, at the Nelson Hotel, with Dr. Henry R. Searle, Rockford, president, Winnebago County Tuberculosis Association, presiding. The speakers included:

Dr. Norman C. Bullock, commissioner of health of Rockford, Responsibility of Sanatorium Boards for Promoting Early Diagnosis of Tuberculosis.
Dr. Robinson Bosworth, Rockford, president, Illinois Tuberculosis Association, Tuberculosis in Apparently Healthy Individuals.

The afternoon program was devoted to the annual meeting of the Winnebago County Tuberculosis Association; guest speakers were:

Dr. Allan J. Hruby, Chicago, The Problems of Case Finding Among High School Students.
Dr. Jay Arthur Myers, Minneapolis, The Problem of Tuberculosis and Case Finding Among College Students.

Dr. Myers also addressed the annual meeting of the Winnebago County Tuberculosis Association early in the afternoon. Dr. Bosworth presented his presidential address after the banquet in the evening and Dr. James Burns Amberson Jr., New York, discussed "The Menace of Tuberculosis in Young People." All officers were reelected.

Chicago

Society News.—The Chicago Society of Internal Medicine was addressed, May 24, by Drs. Leroy H. Sloan and David Slight on "Syphilis: A Comparison of Wassermann and Kahn Reactions in a Series of 500 Positive Patients" and "Migraine" respectively. Dr. Walter Lincoln Palmer delivered the presidential address on "Graduate Education in Clinical Medicine." —Dr. Philip S. Hench, Rochester, Minn., discussed "Some Axiomatic Generalizations Useful in the Differential Diagnosis of Joint Diseases" before the Chicago Club for the Study of

Arthritis, May 12.—The Chicago Urological Society was addressed by Drs. Hymen J. Burstein, Decatur, on "Double Kidney with Y-Shaped Ureter and Ureteral Calculus in an Infant." A symposium on metastatic infections of the kidney was presented by Drs. Vincent J. O'Connor, Chicago, and Homer G. Hamer, Indianapolis, and case reports by Drs. Charles M. McKenna and Edward W. White. —Dr. Haven Emerson, New York, will address the Health Division of the Council of Social Agencies, June 15, on "The District Health Center—An Indispensable Instrument of the Civil Government of Large Cities."

IOWA

Personal.—Dr. Eugene L. Walsh, Hawkeye, has been appointed in charge of the Washington County Public Health Unit, succeeding Dr. Regnar M. Sorenson, Washington. —E. W. Neenan, D.D.S., Sioux City, has been appointed a member of the state conservation commission to succeed Dr. Everett E. Speaker, Lake View, who resigned.

Annual Clinic.—Mercy Hospital, Des Moines, held its third annual clinic June 2-3. The program included clinics, lectures and case presentations. At the annual banquet, the first evening, the speakers included Dr. Walter D. Abbott, president of the hospital staff, who presided; Joseph H. Allen, mayor of Des Moines, and Dr. Jacob Arnold Bargen, Rochester, Minn., who discussed "The Early Diagnosis of Intestinal Diseases."

State Medical Election.—Dr. Arthur W. Erskine, Cedar Rapids, was named president-elect of the Iowa State Medical Society at its annual meeting in Sioux City recently and Dr. Edward M. Myers, Boone, was inducted into the presidency. New vice presidents are Drs. Kenneth L. Johnston, Oskaloosa, and Archibald F. O'Donoghue, Sioux City; Drs. Robert L. Parker and Harold J. McCoy, Des Moines, are secretary and treasurer respectively. The next annual meeting will be at Des Moines May 11-13.

KENTUCKY

Personal.—Dr. Charles G. Baker, Louisville, has been appointed health officer of Fulton County to succeed Dr. Gracie R. Rowntree, Hickman, who has been appointed assistant health officer of Louisville, it is reported. —Dr. James C. Hancock, recently a member of the staff of the Indian Medical Service at Fort Apache, Ariz., has been made health officer of Hickman County. —Dr. Joseph J. Gerkins, Bedford, has been appointed health officer of Fleming County to succeed Dr. Chadwick W. Christine, who resigned to accept a similar position in Jefferson County. The change was effective April 30.

MAINE

State Medical Meeting at Belgrade Lake, June 20-22.—The eighty-fifth annual session of the Maine Medical Association will be held at the Belgrade Hotel, Belgrade Lake, June 20-22, under the presidency of Dr. Frederick T. Hill, Waterville. Conferences on miscellaneous topics will be held Monday and Tuesday mornings, at which the guest speakers will include Drs. Joseph H. Shortell and Augustus Thorndike Jr., both of Boston. Other speakers will include:

Dr. Frederick M. Law, New York, X-Ray of the Sinuses and Mastoids.
Dr. Jacob Schloss, Boston, Diagnosis and Follow Up of Chronic Inflammatory Lesions of the Stomach.
Dr. Frederick A. Coller, Ann Arbor, Mich., The Administration of Fluids to the Sick Surgical Patient.
Dr. William C. Quinby, Boston, The Operative Treatment of Urinary Stone.

There will be reunions of alumni of the medical schools of Boston, Johns Hopkins, Bowdoin, McGill and Harvard universities Monday; in the evening, a dinner meeting will be addressed by Dr. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, on medical economics. The annual banquet will be held Tuesday evening, when the presentation of fifty year service medals will be made. The speakers will be Governor Lewis Barrows; Franklin W. Johnson, LL.D., president, Colby College; Colonel Campbell, Sanford; Dr. Harris P. Mosher, Boston, and Kenneth G. Roberts.

MARYLAND

Dr. Harrop Joins Squibb and Sons.—Dr. George A. Harrop, associate professor of medicine, Johns Hopkins University School of Medicine, has been appointed director of research on the staff of E. R. Squibb and Sons, according to Science. A new research laboratory is in process of construction at New Brunswick, N. J., it was stated. Investigation along scientific lines will be carried on without necessary regard to its immediate practical outcome. It is also planned to undertake active clinical investigation with which to supple-

ment and give orientation to the laboratory studies. Dr. Harrop graduated at Johns Hopkins in 1916. He was appointed associate professor of medicine at his alma mater in 1925 and was also in charge of the chemical laboratory and work in diseases of metabolism and endocrinology.

Annual Meeting and Election of Medical Faculty.—Dr. Frank B. Hines, Chestertown, was elected president of the Medical and Chirurgical Faculty of Maryland at its annual meeting in Baltimore, April 27-28. Other officers are Drs. Frank S. Lynn, Baltimore; Richard C. Dodson, Rising Sun, and Everard Briscoe, Prince Frederick, vice presidents, and Walter D. Wise and Joseph Albert Chatard, both of Baltimore, who were reelected secretary and treasurer respectively. The scientific session, under the presidency of Dr. Arthur M. Shipley, included a symposium on present day problems of the physician with Drs. Richard T. Shackelford, Arthur J. Lomas and Maurice C. Pincoffs as the speakers. At a round table luncheon, the following, among others, spoke:

Dr. Huntington Williams, Occupational Diseases and Industrial Hygiene.

Dr. William F. Rienhoff Jr., Surgical Treatment of Nontuberculous Lesions of the Lungs and Mediastinum.

Dr. John Mason Hundley Jr., Inflammatory Malignant Diseases of the Cervix, Vaginitis Due to the Trichomonas and the Gonococcus, Cystitis and Urethritis.

Dr. Robert P. Bay, Industrial Surgery, Estimation of Permanent Partial Disability.

Dr. Eldridge L. Eliason, professor of clinical surgery, University of Pennsylvania School of Medicine, Philadelphia, delivered the annual Trimble lecture on "The Surgeon's Role in the Right Upper Quadrant," and Dr. Russell M. Wilder, Rochester, Minn., addressed the general meeting on "Clinical Investigations of Insulins with Prolonged Action."

MASSACHUSETTS

Personal.—Dr. Richard J. Neil has been appointed school physician of Methuen, succeeding Dr. Roy V. Baketel, who held the position thirty years.—Otto Krayner, professor of pharmacology, American University of Beirut, Syria, has been appointed associate professor of pharmacology at the Harvard University Medical School for five years beginning next September.

Conference on Health Education.—The twelfth annual conference of the New England Health Education Association was held at the Massachusetts Institute of Technology, Cambridge, June 4-5. Speakers included:

Lura Oak, Ph.D., Cambridge, Massachusetts Department of Public Health, Reading Disability and Its Relation to Social Maladjustment. Julia Ernestine Becker, A.M., associate in biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Recent Progress in Nutrition: Its Significance.

Dr. Rolf Lium, Boston, extension secretary, Massachusetts Society for Social Hygiene, Social Hygiene in Health Education.

C. E. Turner, Dr.P.H., Cambridge, New Findings Concerning Intermittency in Growth.

Dr. Henry B. Elkind, Boston, medical director, Massachusetts Society for Mental Hygiene, Mental Hygiene in Education.

Society News.—Dr. George G. Smith, Boston, was elected president of the Massachusetts Society for Social Hygiene at its annual meeting in Boston, April 13.—Dr. Martha Brünner-Ornstein, Vienna, Austria, addressed the New England Physical Therapy Society, April 21, on "Recent Advances in Physical Therapy," and Dr. Afley Leonel Brett, Boston, "Low Back Strain."—A symposium on schizophrenia was presented before the Boston Society of Psychiatry and Neurology, April 15, by Dr. Louis H. Cohen, Hudson Hoagland, Ph.D., and Dr. Roy G. Hoskins.—Among others, Drs. Karl Jefferson Thomson and Mandel E. Cohen discussed "Changes in the Electrocardiograms and in the Contour of the Heart in Normal Pregnant Women" before the New England Heart Association, Boston, April 12.

MICHIGAN

Medical School to Publish a Journal.—The *Journal of the Wayne University College of Medicine* will make its appearance in June and will hereafter be published quarterly. The entire business and editorial staff is composed of members of the junior and senior classes of the medical college, while a faculty alumni board will serve in an advisory capacity. This is the first time the publication of a bulletin has been attempted by the students.

Medical Supplement in Detroit Free Press.—The Wayne County Medical Society is preparing a medical supplement, which will appear in the *Detroit Free Press*, June 20. Special committees have been appointed to prepare outlines of progress during the past twenty years in various medical specialties. The supplement will also include a diagram of the

administrative set up, and feature articles on the history and activities of the society. There will also be stories on the woman's auxiliary, the medical school and the board of health.

Personal.—Dr. Frederick G. Novy, Ann Arbor, was made an honorary member of the Wayne County Medical Society May 17.—Dr. Ragnar T. Westman, Bay City, has been appointed director of the recently organized Bay County Health Department. With his appointment, it was stated that the organization of the thirty-two county and district health departments in this state has been completed, serving 54 per cent of the rural population and 10.7 of the urban population.—Alfred F. Way has been appointed superintendent of Bronson Hospital, Kalamazoo.—Dr. Francis De Salvo has been named health officer of Niagara for two years.

MINNESOTA

University News.—Dr. Robert S. Stone, San Francisco, gave the annual address in the University of Minnesota Cancer Institute Lectureship, May 4, on "Theoretical and Practical Considerations of Supravoltage X-Rays, Neutrons and Artificial Radioactive Substances for Treatment of Cancer."

Radiologic Society Election.—Dr. Walter H. Ude, Minneapolis, was chosen president of the Minnesota Radiological Society at its recent annual meeting in St. Paul; Dr. Leo G. Rigler, Minneapolis, vice president, and Dr. Harry M. Weber, Rochester, secretary-treasurer.

New Health Officer of Rochester.—Dr. Thomas B. Magath, associate professor of pathology, bacteriology and immunology, Graduate School of Medicine, University of Minnesota, has been appointed health officer of Rochester, succeeding Dr. Charles H. Mayo, who held the position for twenty-five years.

Dr. Edgar Brown Reaches Retirement Age at Minnesota.—Dr. Edgar D. Brown, associate professor of pharmacology at the University of Minnesota School of Medicine, recently reached the retirement age. In 1902 Dr. Brown graduated from Western Reserve University School of Medicine, Cleveland, where he served from 1903 to 1906 as a member of the faculty. Since that time he has been associated with the University of Minnesota.

Ordinance Requires Ambulances to Carry Splints.—An ordinance was approved by the mayor of Crookston, April 16, requiring all ambulances to be equipped with first aid and splint appliances, to be sanctioned by the board of health, and requiring an attendant with a certificate of fitness. Passed through the efforts of Dr. Arthur Kahala, the ordinance applies to any ambulance or other vehicle, used for the transportation or conveyance of the sick or injured. The fracture committee of the state medical association and the regional committee of the American College of Surgeons are endeavoring to have similar ordinances passed in every city and town throughout the state in which ambulances are operated, to provide for proper splinting of fractures before the patients are transported to hospitals.

MISSOURI

Personal.—Dr. Richard Weissenberg, for many years a member of the medical faculty of the University of Berlin, has been appointed visiting professor of cytology at Washington University School of Medicine, St. Louis.

State Medical Election.—Dr. Bernard W. Hays, Jackson, was chosen president-elect of the Missouri State Medical Association at its annual meeting in Cape Girardeau, May 12, and Dr. Dudley S. Conley, Columbia, was installed as president. Dr. Edward J. Goodwin, St. Louis, continues as secretary. The next annual session will be held in Jefferson City.

Society News.—A Missouri chapter of the National Society for the Advancement of Gastro-Enterology has been formed in St. Louis with forty-one charter members. Dr. Horace W. Soper is president, Dr. Frank D. Gorham vice president, Dr. Charles W. Duden secretary and Dr. Lee Pettit Gay treasurer.—Dr. Oliver S. Gilliland has been elected president of the Kansas City Eye, Ear, Nose and Throat Society, succeeding Dr. William Byron Black.—The St. Louis County Medical Society was addressed, April 14, by Drs. Oscar P. Hampton Jr. on "Modern Treatment of Fractures of the Hip" and Clinton W. Lane, "Diagnosis and Treatment of Ringworm Infection of the Hands and Feet."—Drs. Joseph W. Gale, Madison, Wis., and Morris B. Simpson, Kansas City, were among the speakers before the Jackson County Medical Society, May 25; their subjects were "Advantages of Surgery in the Treatment of Pulmonary Tuberculosis" and "Feeding Problems in Laryngeal Tuberculosis" respectively.

NEBRASKA

District Meetings.—The spring meeting of the Third Council District was held at Humboldt, April 15, with addresses by the following members of the faculty of Creighton University College of Medicine, Omaha: Drs. John R. Kleyla, on "Recent Advances in the Treatment of Pneumonia"; Ralph H. Luikart, "Care of the Cervix in the Prevention of Cancer of the Uterus," and Earl A. Connolly, "Treatment of Leg Ulcers and Varicose Veins."—Drs. Abram E. Bennett and Richard H. Young, Omaha, addressed the Sixth Council District Medical Society at Wahoo, April 28, on "Recognition and Treatment of the Common Neuroses" and "Recognition, Management and Treatment of the Psychoses" respectively.

NEW HAMPSHIRE

Personal.—Dr. John F. Gile, Hanover, has been appointed a life trustee of Dartmouth College. Dr. Gile is the son of Dr. John M. Gile, 1887, who was also a Dartmouth trustee.

State Medical Election.—Dr. Clarence O. Coburn, Manchester, was chosen president-elect of the New Hampshire Medical Society at its annual meeting in Manchester, May 17, and Dr. Samuel T. Ladd, Portsmouth, was installed as president. Dr. Carleton R. Metcalf, Concord, was reelected secretary.

NEW JERSEY

Fifty Years of Practice.—Drs. Henry B. Diverty, Woodbury, and Eugene Z. Hillegass, Mantua, were honored with a surprise dinner in Woodbury, April 16, given by the Gloucester County Medical Society to celebrate their completion of fifty years in the practice of medicine. Both physicians are past presidents and the two oldest members of the society, it is reported.

Society News.—Dr. Irving Sherwood Wright, New York, addressed the Middlesex County Medical Society, Metuchen, recently, on "The Present Status of Treatment of Peripheral Vascular Diseases." Dr. Paul Reznikoff, New York, addressed the society recently on "Hematological Problems in the Practice of Medicine."—Dr. Temple S. Fay, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, recently, on "Mechanism of Headache; Its Diagnosis and Treatment."—Dr. Charles Gordon Heyd, New York, President of the American Medical Association, addressed the Hudson County Medical Society, Jersey City, recently, on "Classification and Treatment of Goiter."—Dr. Frank W. Konzelmann, Philadelphia, addressed the Essex County Anatomical and Pathological Society in Newark recently on "Clinical Pathology in Bright's Disease." Dr. Arthur M. Fishberg, New York, discussed the paper.—Dr. George J. Heuer, New York, addressed the Bergen County Medical Society, Hackensack, April 13, on "Errors in the Diagnosis and Treatment of Acute Abdominal Conditions."

NEW MEXICO

Personal.—Dr. Harrison Eilers, Los Lunas, has been appointed health officer of the eighth district, with headquarters at Los Lunas. He succeeds Dr. Julian O. Long, who went to the third district in Albuquerque.

State Medical Election.—Dr. Eugene W. Fiske, Santa Fe, was chosen president-elect of the New Mexico Medical Society at its annual meeting in Clovis, May 14, and Dr. George W. Jones, Clovis, was inducted into the presidency. Dr. George T. Colvard, Deming, was elected vice president and Dr. Leo B. Cohenour, Albuquerque, was reelected secretary.

NEW YORK

Changes in Faculty at Albany.—Dr. John A. Sampson will relinquish the chairmanship of the department of gynecology and obstetrics at Albany Medical College, July 1, having reached the retirement age, according to the *New York Times*. He will continue his association with the school as Alden March professor of gynecology. Dr. Arthur W. Elting, professor of surgery for twenty-six years, will also retire, July 1, on account of having reached the age limit.

New Typhoid Carriers.—Forty-five new typhoid carriers were declared in 1936, giving a total of 383 carriers in the state, according to a report of the state department of health. Of the twenty-four carriers whose names were removed from the register during the year, eleven died; three were released from restrictions after submission of the required number of negative specimens following cholecystectomy, while the names of ten were removed because of change of residence of the

carrier to a community outside the jurisdiction of the department. Eighteen of the newly registered carriers were discovered through epidemiologic investigation of outbreaks and twenty-one through the requirement of release cultures from cases of typhoid. Only one large outbreak was traced to a carrier in 1936. This carrier had not previously been detected but was believed to have caused seven cases in an unsolved outbreak in 1932 and nine cases during the outbreak in 1935. Only ten cases of typhoid were traced to previously known carriers; of this number four were unimmunized household contacts of carriers.

New York City

Gifts to Columbia.—Gifts to Columbia University for medical research recently include the following:

John P. Pierce Foundation, \$35,800 for research in bacteriology.
W. K. Kellogg Foundation, \$10,000 for the study of rheumatic fever.
Rockefeller Foundation, \$3,500 for research on constitutional aspects of disease, under the direction of Dr. George Draper; \$4,000 for further study of "visual purple," vitamin A and vision under direction of Prof. Selig Hecht, and \$1,500 for research in nutritional encephalomalacia and muscular dystrophy, under direction of Hans T. Clarke.
Smith, Kline and French Laboratories, \$2,800 for research in pharmacology under Dr. Charles C. Lieb.
Chemical Foundation, \$2,500 for research on brain chemistry, under direction of Dr. Frederick Tilney.
The Anna Fuller Fund, \$1,500 for tissue culture work at the Institute of Cancer Research.
William J. Matheson Foundation, \$1,125 to be added to the Matheson Encephalitis Fund.

Society News.—Drs. Edward N. Packard, Saranac Lake, and Pol N. Coryllos addressed the Medical Society of the County of Kings, April 20, on medical and surgical aspects, respectively, of intrathoracic suppuration.—Dr. Jefferson C. Pennington, Nashville, Tenn., addressed the genito-urinary section of the New York Academy of Medicine recently on "Conservative Management of Damaged Renal Tissue."—Drs. Percy S. Pelouze and David Melvin Davis, Philadelphia, addressed the Medical Society of the County of Queens, recently, on "Prevention and Treatment of Venereal Disease" and "The Surgical Aspect of Venereal Disease" respectively.—A program on heart disease arranged by the Bronx Pathological Society was presented before the Bronx County Medical Society, April 21, by Drs. Louis R. Ferraro, William Aronson and Joseph C. Ehrlich.

Mr. Van Cleve is Dead.—Edward M. Van Cleve, principal emeritus of the New York Institute for the Education of the Blind, died at his home, May 21, aged 70. Mr. Van Cleve had assisted in the formation in 1915 of the National Society for the Prevention of Blindness, sponsored by the Russell Sage Foundation, and became its first managing director, a position he held for nine years. At one time he was president of the Ohio State Commission for the Blind and in 1907 was superintendent of the Ohio State School for the blind. In 1931 Mr. Van Cleve was awarded the Leslie Dana Gold Medal by the National Society for the Prevention of Blindness in cooperation with the St. Louis Society for the Blind, through which the medal is offered by Leslie Dana, St. Louis, for "outstanding achievements in the prevention of blindness and the conservation of vision."

NORTH CAROLINA

Extension Course in Sixteen Counties.—A series of lectures for physicians was presented during March and April in sixteen counties under the auspices of the University of North Carolina School of Medicine and the extension division of the university. The speakers included Drs. Stewart R. Roberts, Atlanta; Thomas Grier Miller, Philadelphia; Howard Fox, New York; James R. McCord, Atlanta; Christian P. Segard, Leonia, N. J.; George P. Müller, Philadelphia, and Charles F. McKhann, Boston. The counties in which the course was given are Wake, Franklin, Warren, Granville, Johnston, Edgecombe, Nash, Wilson, Cumberland, Person, Chatham, Vance, Hartnett, Lee, Wayne and Orange.

All Servants to Be Examined for Syphilis.—All domestic servants in North Carolina are required to have an examination at least once a year, or as often as the employer desires, to determine the presence of syphilis or tuberculosis, in accordance with a law recently enacted in the state. Domestic servants presenting themselves for employment must, under the law, furnish the employer with a certificate from a practicing physician or the public health officer of the county in which they reside, certifying that they have been examined within two weeks prior to the time of presentation of the certificate, that they are free from all contagious, infectious or communicable diseases, and showing the nonexistence of any venereal disease that might be transmitted. The original report showing the tests to be negative from a laboratory approved by the state board of health for making Wassermann and other tests must accompany the certificate.

NORTH DAKOTA

State Medical Election.—Dr. William H. Long, Fargo, was chosen president-elect of the North Dakota State Medical Association at its annual meeting in Grand Forks, May 18, and Dr. Edwin L. Goss, Carrington, was installed as president. Vice presidents are Drs. Harry A. Brandes, Bismarck, and Cyril J. Glaspel, Grafton. Dr. Albert W. Skelsey, Fargo, was reelected secretary, and Dr. William W. Wood, Jamestown, treasurer. The next annual meeting will be held in Bismarck. A tribute was paid to the first president of the society, Dr. Joseph G. Millspaugh, as a feature of its fiftieth anniversary, when excerpts from the first annual report were read by his daughter, Mrs. A. W. Ide, St. Paul. Another notable feature of the annual session this year was the special ceremony held in honor of fourteen members of the society who were licensed to practice in Dakota Territory before North Dakota became a state in 1889. Dr. James Grassick, Grand Forks, the only member known to have attended the organization meeting, presided. The fourteen members are Drs. James P. Ayleen, Grafton; Frederick N. Burrows, Bathgate; Andrew Carr, Minot; Edward I. Donovan, Langdon; Amos A. Flaten, Edinburg; Charles B. Harris, Pembina; Arthur T. Horsman, Devils Lake; George McIntyre, Long Beach, Calif.; Charles MacLachlan, San Haven; Henry O'Keefe, Grand Forks; Thomas C. Patterson, Lisbon; William H. Welch, Larimore, and Drs. Grassick and Glaspel.

OHIO

Pharmaceutical Company in New Quarters.—The William S. Merrell Company, Cincinnati, has moved into a newly constructed laboratory, factory and office building which is located just outside the city limits of Cincinnati, near the village of Reading. The buildings are thoroughly modern and there is additional land to provide for future expansion. The company was founded in 1828.

Society News.—At a meeting of the Academy of Medicine of Cleveland, May 21, Dr. Alfred W. Adson, Rochester, Minn., discussed "The Relief of Intractable Pain." The academy presented a "medical musical medley" May 6.—Dr. Linn J. Boyd, New York, lectured at Huron Road Hospital, East Cleveland, June 9, on "Newer Studies in Shock."—Dr. John Alexander, Ann Arbor, Mich., among others, addressed the Clinical Society of the University Hospitals, Cleveland, May 20, on "Pulmonary Abscess and Bronchiectasis."

Rehabilitation After the Flood.—Five members of the U. S. Public Health Service, cooperating with the Ohio State Department of Health, have been stationed in the flooded counties of the state, to assist local health officials in the rehabilitation program now under way. The project includes the restoration of public and private water supplies, the protection of milk and food supplies, disposal of sewage on both public and private property, and disposal of dead animals. According to the state department of health, about 100,000 inoculations against typhoid were administered by the department alone, not counting those given by local physicians, a complete record of which is not yet available. There were 10,000 private wells and cisterns chlorinated. According to *Ohio Health News*, April 1, only three cases of typhoid had been reported up to that time and, in Portsmouth, fewer deaths and more births had been reported during the flood period than in other years during the same period.

OREGON

Plague-Infected Ground Squirrels.—According to *Public Health Reports*, a lot of fifty-six fleas taken from Oregon ground squirrels, shot 14 miles north of Lakeview, in Lake County, were found to be plague infected, May 7.

PENNSYLVANIA

Dr. Buyers Honored.—Dr. Edgar S. Buyers, Norristown, was honored by the Montgomery County Medical Society, April 23, when he concluded twenty years as secretary of the society to become its president. He was presented with a gold watch and chain. Dr. Buyers took office in 1917 and it is reported that he was absent only once and that when he was on official business for the society. He is chairman of the board of trustees of the Medical Society of the State of Pennsylvania and was formerly counselor for the second district.

Philadelphia

Society News.—Dr. Walter Estell Lee, among others, addressed the Philadelphia Pediatric Society, May 11, on "Treatment of Burns with Special Reference to Use of Tannic Acid and Silver Nitrate."—Dr. George Packer Berry, Roch-

ester, N. Y., was the guest speaker before the Pathological Society of Philadelphia, May 13; he discussed "Observations on the Transformation of the Virus of Rabbit Fibroma (Shope) into That of Infectious Myxomatosis (Sanarelli)."

Dr. Krusen Honored.—Dr. Wilmer Krusen, president of the Philadelphia College of Pharmacy and Science since 1927, and formerly president of the Philadelphia County Medical Society, was guest of honor at a dinner, May 26, given by friends and colleagues to celebrate his sixty-eighth birthday. Dr. Krusen was born in Richboro, Pa., May 18, 1869, graduating at Jefferson Medical College in 1896. Beginning his career as a pharmacy clerk in 1886, he became professor of gynecology at Temple University School of Medicine in 1902. He subsequently served as director of public health of Philadelphia, as president of the Philadelphia Obstetrical Society, Philadelphia Clinical Society, the state health association and the Philadelphia Medical Club, and is a member of the committee on public relations of the state medical society.

TENNESSEE

Society News.—Dr. Franklin B. Bogart addressed the Hamilton County Medical Society, Chattanooga, April 22, on "Radiation Therapy in Pelvic Lesions," and Dr. William D. Anderson on "Endocrinology in Childhood."—At a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society in Linden, recently, the speakers included Drs. Watt Yeiser, Columbia, on "Indications for and Demonstration of Practical Oxygen Therapy"; Frank E. Whitacre, Memphis, "Treatment of Eclampsia," and Charles M. Hamilton, Nashville, "Treatment of the Commoner Skin Diseases."—Dr. Walter M. Luttrell, Knoxville, addressed the Knox County Medical Society, April 6, on diabetes mellitus.—A symposium on thyroid disease was presented before the Memphis and Shelby County Medical Society, April 20, by Drs. William C. Chaney, Casa Collier, Walter W. Robinson and William R. Bethea.

VIRGINIA

Portrait of Dr. Long.—The section on the history of medicine of the Richmond Academy of Medicine, Richmond, presented a portrait of Dr. Crawford W. Long to the academy at a meeting, April 13. The presentation was made by Dr. Carrington Williams and the speech of acceptance by Dr. Marvin Pierce Rucker, president of the academy, both of whom discussed the historical aspect of anesthesia. Other speakers were Drs. Beverley R. Tucker, who reviewed the life and work of Charles Edward Brown-Sequard, and Hubert A. Royster, Raleigh, N. C., "The Adventurous Life of Edward Warren Bey."

WISCONSIN

Board Denies Recognition to Foreign Graduates.—Graduates of foreign medical schools, with the exception of graduates of Canadian schools, will not be recognized in the future by the Wisconsin State Board of Medical Examiners, in accordance with a resolution unanimously approved by the board recently. The action was taken because of the board's inability to determine the reputability of the foreign schools concerned, it was stated.

Personal.—Dr. Frank O. Brunckhorst has been appointed health officer of Neenah, succeeding Dr. Bryce K. Ozanne, resigned, effective May 1.—Dr. Lewis Rothman was honored at a reception, April 4, given by the civic clubs of Wittenberg, in recognition of his fifty years in the practice of medicine. He is a charter member of the Shawano County Medical Society.—Dr. Timothy L. Harrington, Milwaukee, a member of the staff of the Wisconsin Anti-Tuberculosis Association since 1919, has been appointed medical director of River Pines Sanatorium, Stevens Point, succeeding Dr. Harold M. Coon, who has been named superintendent of the state tuberculosis sanatorium at Statesan.

HAWAII

Lectures on Obstetrics and Pediatrics.—A series of lectures on obstetrics and pediatrics was given at various places in Hawaii recently under the auspices of the bureau of maternal and infant hygiene cooperating with the Hawaii Territorial Medical Association. The lecturers were Drs. Fred L. Adair, professor of obstetrics and gynecology, Medical Department, Division of Biological Sciences, University of Chicago, and Clifford G. Grulee, clinical professor of pediatrics, Rush Medical College, Chicago. The program included a public talk at Kahului and Lihue and a repetition of the lectures before the Kauai County Medical Society.

GENERAL

Study of Neoplastic Diseases.—The American Association for the Study of Neoplastic Diseases will hold its next meeting at Johns Hopkins Hospital, Baltimore, June 24-25. A demonstration of microscopic pathology will make up the program. Members wishing to present a case should send 100 micro sections of the material to Dr. Charles F. Geschickter at the hospital. The September meeting of the association will be held at the Mayflower Hotel, Washington, D. C., September 9-11.

New Publication on Tumor Therapy.—A new monthly journal, the *Review of Tumor Therapy*, has made its appearance. It presents practical information that will be usable in treating patients and the latest methods and procedures. It will also correlate the essentially related fields of surgery, radiology and pathology. The editorial committee is composed of Drs. Isaac A. Bigger, Richmond, Va.; Robert S. Cathcart, Charleston, S. C.; Charles F. Geschickter, Baltimore; Benjamin Gruskin, Philadelphia, and Kenneth M. Lynch, Charleston. The editorial and business address is P. O. box 508, Charleston, S. C.

Courses for Teachers of Sight-Saving Classes.—The National Society for the Prevention of Blindness announces that courses of training for teachers and supervisors of sight-saving classes will be offered at several colleges during the summer sessions. Elementary courses will be given at Western Reserve University, Cleveland, June 21 to July 30; Wayne University, Detroit, June 29 to August 6, and Teachers College, Columbia University, New York, July 12 to August 20. Courses for advanced students will be offered at Western Reserve University, June 28 to July 31, and Teachers College, Columbia, July 12 to August 20. Details may be obtained from the director of the course at each school.

Association for the Advancement of Science (Section N).—The one hundredth meeting of the American Association for the Advancement of Science will be held in Denver, June 21-26. In the section on medical sciences (N) the program Tuesday and Wednesday will include a symposium on diseases caused by acid-fast bacteria. A discussion of leprosy will make up the program Thursday, while Friday's session will open with a memorial address on the life of Dr. Henry Sewall. The presentation of papers on tuberculosis and diseases of the chest will conclude the session. Speakers at the various sessions will include:

Dr. Edward Jackson, Denver.
Dr. Florence R. Sabin, New York.
Mr. Perry Burgess, New York, president, American Leprosy Foundation.

New Book of Abstracts on Anesthesia.—The Journal Club of the Section on Anesthesia, Mayo Clinic, Rochester, Minn., has compiled a group of abstracts on anesthesia under the title "Anesthesia Abstracts Volume I." The work was supervised by Dr. John S. Lundy with the assistance of Dr. Richard M. Hewitt and the division of publications of the clinic. The first issue contains 207 abstracts from eighty-eight journals, the work of thirty-five abstracters, and, in order to avoid conflict, each abstract differs from abstracts appearing elsewhere. Priced at \$2, the compilation may be purchased from the Burgess Publishing Company, 426 South Sixth Street, Minneapolis. Volume II is now in process of publication, but the appearance of subsequent issues will depend on the preparation of a sufficient number of abstracts to warrant it and the evidence that they are wanted. It was announced that the principal need is for English abstracts of foreign articles.

The Rocky Mountain Conference in Denver.—The first Rocky Mountain Medical Conference, sponsored by the state medical societies of Colorado, New Mexico, Utah and Wyoming, will be held in Denver, July 19-21. The object is to bring together practitioners of the Mountain states and adjoining Middle West and Southwest states to hear discussions of general interest but especially to discuss problems peculiar to the region: Rocky Mountain spotted fever, silicosis among quartz miners, and sanitary problems incident to the tourist influx. Speakers will include Drs. Thomas Parran, surgeon general, and Roscoe R. Spencer of the U. S. Public Health Service, Washington, D. C.; Walter C. Alvarez, Rochester, Minn.; Walter E. Dandy, Baltimore; Julius H. Hess, Herman L. Kretschmer and Walter L. Palmer, Chicago; Hayes E. Martin, New York; William B. Carrell, Dallas; Leo G. Rigler, Minneapolis; Charles C. Dennis, Kansas City, Mo.; Gabriel Tucker, Philadelphia; Sterling Bunnell, San Francisco; Andrew J. Browning, Portland, Ore., and Earl C. Sage, Omaha.

Trailer Camp Sanitation.—At the annual conference of State and Provincial Health Authorities of the United States and Canada with the U. S. Public Health Service at Washington in April the committee on interstate relations offered

recommendations directed toward improvement of sanitation in trailer camps. It was first urged that state health departments make efforts to acquaint tourists with their obligations to the rest of a community by working with tourist and trailer organizations in disseminating information concerning precautions to be observed. Suitable regulations under general health laws and enactment of such general laws where they do not exist were recommended, but the committee advised against specific laws unless absolutely necessary. Finally it was suggested that a special committee on trailer sanitation be appointed to cooperate with tourists' organizations and trailer manufacturers with a view to the standardization of type, size and location of waste water and sewage outlets to facilitate the design of camp sewer systems.

Association of Genito-Urinary Surgeons.—The forty-ninth annual meeting of the American Association of Genito-Urinary Surgeons will be held at the Seignior Club, P. Q., Canada, June 14-16. The following speakers are included on the program:

Drs. William F. Braasch, Rochester, Minn., and James W. Merriks Jr., Clinical and Radiologic Data with Congenital and Acquired Single Kidney.
Drs. David W. MacKenzie, Montreal, and Allan B. Hawthorne, The Ectopic Kidney: Surgical Aspects in a Series of Ectopic Kidneys.
Drs. Alexander R. Stevens, New York, and William R. Delzell, Traumatic Rupture of the Bladder with Data on Twenty-Seven Cases.
Drs. Roger C. Graves, Boston, and Richard Dresser, Experiences with High Voltage Roentgen Therapy in the Treatment of Malignant Tumors of the Urinary Bladder.
Drs. Hugh Cabot and John M. Pace, Rochester, Minn., Methods of Selecting the Proper Operative Treatment for Cancer of the Bladder.
Dr. Hugh H. Young, Baltimore, Progress in Urology, Retrospective and Prospective.
Drs. David W. MacKenzie, Montreal, and Magnus I. Seng, Montreal, Obliteration of the Ureter in a Congenital Kidney with Hydro-nephrosis.
Drs. Ira R. Sisk, Madison, and Otto E. Toenhart, Madison, Glucuronic Acid as a Urinary Acidifying Agent.
Drs. Archie L. Dean Jr., New York, and Joseph H. Farrow, Erythroplasia of the Penis.

Society News.—Dr. Walter E. Garrey, Nashville, Tenn., was elected president of the American Physiological Society at its recent annual meeting, and Dr. Andrew C. Ivy, Chicago, reelected secretary. The next annual session will be held in Baltimore, probably in April.—At a meeting of the American Society for Clinical Investigation, May 3, Dr. John R. Paul, New Haven, Conn., was chosen president, and Dr. Joseph M. Hayman Jr., Cleveland, reelected secretary. The next annual meeting will be held in Atlantic City, N. J., May 2, 1938.—Dr. Neil Dayton, Boston, was chosen president-elect of the American Association on Mental Deficiency at its annual meeting in Atlantic City, May 5-8, and Dr. Harry C. Storrs, Wassaic, N. Y., was installed as president. Dr. E. Arthur Whitney, Elwyn, Pa., was reelected secretary and Richmond was named for the place of the next annual meeting.—At the annual session of the American Society of Biological Chemists, April 23, Glenn E. Cullen, Ph.D., Cincinnati, was elected president; William C. Rose, Ph.D., Urbana, Ill., vice president, and Henry A. Mattill, Ph.D., Iowa City, was reelected secretary. The next annual meeting will be held in Baltimore.—Dr. Kenneth D. Blackfan, Boston, was chosen president of the American Pediatric Society, May 1, and Dr. Hugh McCulloch, St. Louis, reelected secretary. The next annual session will be in Bolton Landing, N. Y., June 9-11.—Dr. George R. Minot, Boston, was chosen president of the Association of American Physicians at its annual meeting in Atlantic City, May 5; Dr. Eugene F. Du Bois, New York, vice president, and Dr. Hugh J. Morgan, Nashville, Tenn., was reelected secretary.

Changes in Status of Licensure.—The California State Board of Medical Examiners reports the following action taken at its meeting February 8-11:

Dr. Edward H. Anthony, Los Angeles, probation for three years without narcotic privileges.
Dr. Francis James Bold, Montebello, license restored, placed on probation for five years.
Dr. Samuel D. Burgeson Jr., Los Angeles, placed on probation for five years without narcotic privileges.
Dr. Merton E. Eastman, San Andreas, probation for three years.
Dr. Thomas Flint Jr., Redding, license revoked for narcotic addiction.
Dr. James Harvey Johnston, San Francisco, probation for five years without narcotic privileges.
Dr. John G. Lenz, Redondo Beach, license restored; placed on probation for five years.
Dr. Ramon Lopez, Brawley, license restored, placed on probation for five years without narcotic privileges.
Dr. Leroy J. Otis, Norwalk, placed on probation for five years without narcotic privileges.
Dr. Allen H. Peck, Ventura, placed on probation for five years without narcotic privileges.
Dr. Byron H. Pelton, Compton, license restored, probation for five years without narcotic privileges.
Dr. Leo Morton Schulman, Los Angeles, license revoked, for alleged narcotic dereliction.
Dr. Henry C. Wallace, Fresno, placed on probation for five years without narcotic privileges.

Extension of the Use of Cesarean Section

At a meeting of the North of England Obstetrical and Gynecological Society, Prof. A. M. Claye advocated a wider use of cesarean section, which a few years ago was almost limited to cases of contracted pelvis and of occasional cases of fibroids or ovarian tumors obstructing labor. The operation had a high mortality when done late in labor, because the uterus was already infected. The infection easily passed through the wound into the general peritoneal cavity. It was therefore considered that when intervention was necessary late in labor and forceps delivery was impossible owing either to small dilatation of the cervix or to excessive disproportion, craniotomy was the safer operation. But the introduction of the lower segment operation had altered this. It was definitely safer than craniotomy, except possibly in some cases in which forceps had failed. If the uterine wound became infected, the peritonitis was likely to be pelvic, with low mortality. The lower segment had the advantage over the classic section that the scar was situated in a quieter part of the uterine muscle, less liable to the stresses and strains of contraction and relaxation during the puerperium. A better scar formed with less danger of rupture in a subsequent pregnancy. Finally, there was less danger of the scar contracting dangerous adhesions to other organs.

INDICATIONS FOR THE LOWER SEGMENT OPERATION

Claye has performed the lower segment operation in thirty-five cases in four years, seventeen of which were cases of contracted pelvis. He now carries out trial labor in all cases of disproportion unless the pelvis is very small. He allows a variable time for the head to engage after rupture of the membranes, provided there is no maternal or fetal distress. Of the remaining cases four were examples of inertia and five of occipitoposterior position. He considered the operation particularly advantageous for the late case. Here the lower segment is thinned out and the hemorrhage is negligible. But if the operation is performed before labor the lower segment is often not formed and thick muscle has to be incised. There is much hemorrhage, which is difficult to control. Therefore for patients operated on before labor, when the risk of infection is minimal, Professor Claye still performs the classic cesarean section. Other indications for which he sometimes performed the lower segment operation were heart disease (when he intended to perform the classic operation but the patients forestalled him by going into labor), carcinoma of the cervix and brow presentation.

INDICATIONS FOR THE CLASSIC OPERATION

Claye's classic cesarean sections numbered 125, of which ninety-two were performed for contracted pelvis with disproportion. The two next most frequent indications were heart disease and placenta praevia (seven cases each). The decision to operate for heart disease was reached in consultation with a cardiologist. If the patient was considered fit to stand the operation and unlikely to bear the strain of another pregnancy well, section with bilateral salpingectomy was done. All the mothers and babies did well. Cesarean section has the great advantage that sterilization can be carried out at the same time. Claye seriously considers section in all cases of complete placenta praevia in a primipara in good condition when the baby is alive and in good condition. As the lower segment is seldom thinned out in placenta praevia and may show large vessels, Claye always does the classic operation. But his treatment of choice for placenta praevia is Willett's forceps.

Toxemia he considers a rare indication for cesarean section. In one case it was chosen in order that the patient might be sterilized at the same time. He no longer performs section for accidental hemorrhage, as he believes that it increases the maternal risk.

The Radium Treatment of Cancer

The seventh annual report of the National Radium Trust and Radium Commission, which has just been published, reviews the radiotherapy of cancer in Great Britain as carried out at thirteen national centers and a number of smaller centers and recognized hospitals. In most there has been a tendency to replace the interstitial use of small quantities of radium by the external application at a considerable distance of large quantities. A difficulty in attempting to assess the value of different methods of treatment by the use of survival rates is that a large number of combinations of different methods of treatment have been used. In the treatment of carcinoma of the breast for example, as many as eighty-six combinations were distinguished. The most noticeable change in treatment is an increasing use of high voltage x-rays and a diminution in the practice of interstitial needling in carcinoma of the cervix. In carcinoma of the breast the main change has been in the use of surface radiation. Patients with carcinoma of the breast in later stages have a slightly better three year survival rate under interstitial irradiation combined with excision than under the former alone. In carcinoma of the cervix, x-rays combined with the "Stockholm method" give a greater freedom from recurrence than the latter alone. In carcinoma of the tongue a high mortality is found associated with the operation of block dissection of the cervical glands.

CANCER OF THE BREAST

For the purpose of analysis, the cases have been divided into three stages: (1) growth limited to the breast, (2) axillary glands invaded, (3) further invasion. When the growth was

Percentage Net Survival Rates from All Methods of Treatment in Which Radium Was Employed

Stage of Disease	Net Survival Rate at	
	Three Years	Five Years
1.....	70.1 (340)	50.0 (109)
2.....	40.3 (627)	22.4 (144)
3.....	18.8 (711)	13.6 (219)
All stages.....	37.2 (1,678)	24.6 (472)

The number of cases is given in parentheses.

Percentage Net Survival Rates from All Methods of Treatment in Which Radium Was Employed

Stage of Disease	Net Survival Rate at	
	Three Years	Five Years
1.....	67.1 (370)	49.4 (65)
2.....	48.4 (539)	43.7 (122)
3.....	29.8 (788)	24.0 (193)
4.....	12.6 (351)	7.2 (72)
All stages.....	37.3 (2,058)	31.1 (475)

still in stage 1, more than two thirds of the patients were alive at the end of the third year after treatment and half were alive five years after treatment. The low survival rate in stage 3 is accounted for by the fact that in many cases only palliative treatment was possible.

CARCINOMA OF THE CERVIX

Carcinoma of the cervix was considered in four stages: (1) growth limited to the cervix with the uterus mobile; (2) lesion spreading into fornices with or without infiltration of the para-

metrium, the uterus retaining some mobility; (3) nodular infiltration of the parametrium with limited mobility of the uterus; (4) massive infiltration of the parametrium extending to the pelvis.

CARCINOMA OF THE TONGUE

In the earliest stage, when the growth is confined to the tongue and no glands are involved, about one half of the patients are alive after three years and one fourth after five years. In the more advanced stages the survival rate is low.

PARIS

(From Our Regular Correspondent)

May 15, 1937.

Regulations for Organization of Public Health Service

France is divided for administrative purposes into eighty-six departments, each of which has a representative of the central government, situated in Paris, termed the prefect, whose duties correspond to those of a state governor in the United States. The departmental service of inspection and control of public health, as created by a law passed in October 1936, is directed by an inspector of hygiene. The minister of public health, Mr. Sellier, issued orders, April 17, which aim to reorganize the public health service of each department on a new basis. The inspector of hygiene will be obliged to live in the principal city (county seat) of the department to which he has been assigned and will be responsible to the prefect for carrying out all instructions received from the ministry of public health. The inspector's reports, after having been sent to the prefect, will be forwarded to the minister of public health in Paris. The inspector of hygiene must be well qualified to deal with all questions relating to public health and social hygiene that may arise. He will have direct control of the work of all organizations receiving state aid and will act as secretary of the departmental council of hygiene and all allied bodies whose purpose is to provide for and coordinate the sanitary organization of his department.

Inspectors must pass an examination, must be French citizens and must have not only the degree of M.D. but also one of public health from a French university. They must also have served three months as assistants in a departmental service of hygiene or in the health department of a city of at least 100,000 inhabitants.

The examining board will include the directors of hygiene and of personnel of the ministry of public health, an inspector general of hygiene, a competent sanitary engineer and two members of the superior council of hygiene chosen from the faculties of the medical schools. The successful candidate will serve a year on probation before being definitely appointed. The age limit for candidates will be 60 years, and they will not be allowed private practice, except in cities of less than 50,000 inhabitants. Any orders pertaining to public health that are issued by mayors of cities or smaller aggregations must now be submitted to the prefect and the council of hygiene of each department before being put into effect.

Cysts of the Lung

At the April 9 meeting of the Société médicale des hôpitaux, Brulé and his associates reported the case of a man, aged 38, with intense dyspnea and bronchitis. He had been treated for asthma and emphysema since the age of 9 years. Radiographic (in profile) examination of the chest revealed the presence of aerohydrous areas at the base of the right lung, on the basis of which a clinical diagnosis was made of congenital pulmonary cysts, which was confirmed at necropsy. There was also an advanced pulmonary emphysema associated with areas of sclerosis, and a number of cavities in the right lower lobe filled with pus. These cavities did not show any of the characteristics of congenital cysts and hence were regarded as pseudo-

cysts, the result of the emphysematous changes. The authors thought that such secondary cysts were often mistaken for congenital cysts.

Armand-Delille and his associates studied congenital cysts (congenital pseudobronchiectases) in children. In pulmonary tuberculosis in children they observed not only cases of typical bronchiectasis associated with previous inflammatory changes but also changes, as seen radiographically, in the form of clear images with a more or less circular outline as confirmed by iodized oil. They were able to find lesions showing the picture of cysts in ten cases at necropsy. In only one had an ante-mortem diagnosis been made, and this with the aid of iodized oil.

The first paper read at the April 16 session was by Sayé of Barcelona, Spain, who stated that there were three principal types of pulmonary air cysts: first, the giant or balloon cyst type, which varies greatly in size; second, the polycystic lobar type of varying aspect, at times difficult to differentiate from tuberculosis; and, third, cysts associated with the obstruction of certain bronchi. The last named are especially important to recognize. These cysts can suppurate and be mistaken for an encysted pleurisy.

Ameuille and Rendu read a paper on the significance of pulmonary cysts in adults. They agreed with the opinion that cysts undoubtedly occur which are of congenital origin, but, in middle aged and older adults, air cysts are found which appear to be of recent origin; i. e., acquired. The authors emphasized the difficulty of differentiating between cysts and other intrapulmonary cavities containing air. Acquired cysts in adults are evidently of emphysematous origin.

Pierre Lereboullet, Marcel Lelong and Jean Bernard presented the thoracic films from a nursling of 4 months who, after a febrile course of short duration, suddenly showed on the films an ovoid gaseous area (occupying the lower half of the left lung) with thin borders. After remaining stationary for two months, the area gradually changed position from the periphery to the center of the lobe and then disappeared. They considered this area an example of a huge emphysema. Two similar cases were recently reported by them as "obstructive emphysema." Debré believed that many cysts were the result of an obstructive emphysema.

Cathala and Brincourt reported a case of multilocular cysts of the lung in a child. In spite of the typical radiologic picture and numerous negative examinations for tubercle bacilli, the child was kept in a sanatorium for fourteen months because of a history of tuberculosis in the family.

Comby believed that there was a close relation between bronchiectases and pulmonary cysts in both the congenital and acquired forms.

A Rapid Method of Production of Tetanus Antitoxin

At the March 13 meeting of the Société de biologie Ramon, Metayer and Mustapha reported a rapid method of obtaining tetanus antitoxin from horses. If the horses have been vaccinated against tetanus one or several years previously and are then immunized with progressive doses of tetanus anatoxin to which tapioca has been added, only three weeks is required after beginning this hyperimmunization before one is able to obtain a serum containing sufficient tetanus antitoxin to be employed in specific treatment. Horses not previously vaccinated and given the same hyperimmunization yield a serum incomparably less rich in antitoxin.

International Congress on Psychiatric Problems in Children

A meeting in Paris on psychiatric problems in children will begin July 24 and end on the 28th. The following specialists will read papers: Hamburger of Austria, Ley of Belgium, Weygandt of Germany, Cerietti of Italy, Bouman of the Netherlands, Claparede of Switzerland, Oseretzky of Russia

and Healy of the United States. The three questions to receive special consideration are (1) general psychiatry, (2) psychiatric problems in school children and (3) psychiatry from the medicolegal standpoint. Those wishing to take part in the congress or to receive information regarding the meetings can write to Dr. Grimbert, 11 rue Duroc, Paris.

Virus Research

An extensive discussion of virus research and virus disease took place recently in the Hamburg Medical Society. Kurt Herzberg, Greifswald hygienist, spoke first on "Virus Research as a Present-Day Activity." Thus far one has had to frame a satisfactory definition of virus in terms of an obligatory cell parasitism. Heretofore, only animal experiments based on photodynamics have produced favorable chemotherapeutic results. In man the chain of infection is quickly broken, as a rule; frequently not a single second transmission occurs. The interrelation of virus and tumors can be demonstrated on the basis of observations made by Rous and Shope. Attention is called to the difference existing between, on the one hand, those chicken sarcomas and rabbit papillomas indisputably produced by virus and, on the other hand, those rabbit carcinomas produced by painting with tar. The infective material of tumors in animals acts with respect to specificity like types of virus. It is a remarkable fact, moreover, that the same virus can exhibit twofold pathogenic properties; the virus of the Shope fibroma, for example, may at first act as a virus of fibroma and again as a virus of inflammation. And there are other examples in point.

Nauck discussed the pathology and cytology of virus diseases. The study of cellular and tissue changes provides in connection with the demonstration of an intracellular agent important data on the biologic behavior of certain types of virus in the organism attacked. The histopathologic alterations that have already for some time been the object of well known exhaustive investigation are in their totality nonspecific for the agents of virus groups. It is a question of inflammatory proliferative and degenerative processes which, according to the type of virus, differ greatly both in extent and chronological succession. Particular types of virus are recognized not only by the difference in the resultant tissue reactions but also by the predilections they possess to attack certain organs or tissues. Observation of the histopathologic reactions provides a basis for a tentative classification, according to the so-called tropisms or affinities for particular cells and tissues. A virus may thus be called neurotropic, dermatotropic, fibrotropic, hematotropic, lymphotropic or pneumotropic, or, conversely, it may be termed polyorganotropic. These special affinities for certain tissues and cells are not absolutely invariable, since they may be dissimilar in different animal species and in altered conditions of infection. This modification of the pathogenic properties is of practical value for the obtaining of vaccines. Then too the appearance of nuclear and cellular inclusions in many types of virus is interpreted as an expression of "cytotropism." Herzberg stressed the fact that in a number of virus diseases the inclusion bodies may be ascribed with certainty to a multiplication and accumulation of the agents within the cell. The circumstances of inclusion body formation, however, vary not only with different types of virus but also according to what cells are affected. The cytopathology of virus diseases requires on this account to be further investigated, especially with respect to the interrelation of intracellular development of virus and the specific cell reaction.

The third speaker was Carl Hegler, clinician. A satisfactory classification of virus disease is, he said, at present not

yet possible, either on the basis of clinical symptoms or according to the manner of transmission, the length of incubation, the amount of the virus, the outlook with regard to immunity or, finally, according to the tropism of a particular virus. Noteworthy in psittacosis is the comparative rarity of transmission from man to man; transmission to a third person has never been known to take place. Psittacosis does not confer complete immunity in every case; reinfections have been reported. Mention was made of the so-called Gordon biologic test for Hodgkin's disease: rabbits and guinea-pigs that are inoculated intracerebrally with a suspension of lymphadenomatous tissue present a meningo-encephalitis, which terminates fatally within ten to thirty days. Transmission from animal to animal does not take place; by filtration the virulence is considerably weakened but not destroyed. Various follow-up observations indicate the presence of a specific, living agent that in all probability is a virus. According to observations of influenza in swine, especially in young pigs, and studies of transmission of the disease, influenza in man may be regarded as a virus disease. The supposition is that the virus infection (by means of a serous inflammation perhaps) acts as a pace-maker for the bacteriologic agent. It seems virtually certain that a similar circumstance, the existence of an unknown virus which performs this pacemaker rôle, underlies scarlet fever, erysipelas and acute articular rheumatism. Whooping cough and dysentery too should perhaps be included in this group. At present there is no specific chemotherapeutic substance available for a single virus disease. Protective material contained in convalescent serum works partial successes in poliomyelitis, measles, scarlet fever and erysipelas. The ideal objectives remain twofold: active protective inoculation with weakened virus (as in variola, rabies and yellow fever) and the production of a virucidal serum.

Studies of Evipan Narcosis

Dr. E. Trevani reported at the last session of the Vienna Physicians' Society on the use of evipan (the sodium salt of *n*-methyl-cyclohexenyl-methyl barbituric acid) to induce narcosis. In 2,500 cases in which this substance was utilized during the last five years the actual methods and the dosages were far from uniform. Clinical observations thus far indicate that it is not necessary to adhere rigidly to any single plan. However, the author found the following routine to be the best and most reliable: The patient is first prepared for narcosis by an injection of morphine. This is followed in from one to one and a half hours by a large initial dose of freshly prepared evipan, which the operator injects into the cubital vein of the opposite arm. Trevani varies the dosage according to the patient's age; patients aged from 20 to 30 receive 5 cc. at one injection, those between the ages of 30 and 45, 4 cc., those aged from 45 to 60, 3 cc. and patients over the age of 60, 1.5 cc. During the course of the operation an additional dose of from 0.5 to 3 cc. is injected as needed and on this account Trevani permits the injection needle to remain in the vein subsequent to the initial injection. As soon as the patient becomes unconscious, as indicated by a relaxation of the lower jaw, the intervention may be begun. Accordingly, all should be in readiness for the surgical procedure before the first injection is administered. Trevani does not estimate beforehand the exact amount of the solution necessary. He favors fractionated injections with large initial doses. Only rarely are patients encountered who show themselves resistant to the drug. In such cases one has to resort to ether narcosis. Since the decomposition of evipan takes place in the liver, any disease of that organ, even a secondary dysfunction, must be viewed as an absolute contraindication of this type of narcosis. Trevani mentions no other

contraindication. In the literature there are recorded eighty-six fatalities in a total of 4,000,000 evipan narcoses. Of these accidents, sixty occurred during the first two years, when the proper technic had not been developed. Overdosing was probably the responsible factor in a large majority of these deaths. On the basis of the foregoing observations, evipan narcosis may be assumed to be at least as safe as ether narcosis. Evipan narcosis offers the following advantages: It permits procedures of diathermy and cauterization to be carried on without danger of an explosion, it renders the use of narcotic masks, an inconvenience in surgical treatment of the throat and head, unnecessary, and it enables the surgeon to perform interventions on patients whose general condition would preclude the use of an ether or chloroform narcosis. Of even greater importance is the favorable psychic effect of the drug on anxious patients, who are often terrified when treated under local anesthesia, for injuries incurred in an accident, for example. Evipan should not be administered to ambulant patients, especially if the operation concerns the floor of the oral cavity, as the duration and profundity of the "after-sleep" cannot be estimated in advance. Patients to whom evipan has been administered must therefore be kept under observation.

In the discussion of Trevani's paper, many of the speakers called attention to the fact that the earlier mistrust of this method of narcosis is rapidly disappearing. In pediatric practice it has already been quite widely used in adenotomies and tonsillectomies, the dosage adjusted to the individual patient. About 1 cc. per minute is administered at both initial and subsequent injections, the amount varying from 1 to 5 cc. (the latter dosage has been administered to boys aged 14 years). Some surgeons have injected adults with total dosages as high as 18 or 20 cc. without apparent injury. In these cases coramin (a 25 per cent solution of pyridine betacarboxylic acid diethylamine) served as an efficient postoperative "awakener." From the standpoint of gynecologic practice, Kahr has found evipan narcosis chiefly useful in the preparation of elderly women patients for complete narcosis before irradiation with radium. An uncontrollable singultus is reported to have been permanently abolished by an injection of 4 cc. of evipan. It was generally conceded in the discussion that the states of motor excitation often observed during or subsequent to evipan narcosis should be attributed chiefly to the administration of the total dose at one injection. Many surgeons spoke favorably of a combination of evipan narcosis with subsequent local anesthesia. The individual surgeon also keeps in mind that in addition to evipan solutions, which have to be constantly prepared afresh there is the finished product "Eunarcon" (likewise a barbituric acid derivative), the fractionated use of which for short or complete narcosis has been quite successful.

Microscopic Representation of the Surfaces of Living Organs

For the observation of living mucosa with the greatest possible microscopic magnification, various instruments and systems of lenses have been employed, the cystoscope, the colposcope and others. Thus far, however, enlargements up to a magnification of only about 30 diameters have been practicable for the observation of surfaces, and the instruments did not permit inspection of individual cells or their constituents. Dr. Pick, who holds the chair of anatomy at Vienna, has recently devised a new apparatus, which he demonstrated before the Physicians' Society. By means of this device he is able to obtain magnifications of 800 diameters of mucous surfaces and of surgically exposed organs. The apparatus consists principally of a microscope tube with an ocular and an exchangeable objective that is enclosed from the outside by a glass cover. There is also a small lamp that provides illumination. The tube may be inserted in any natural bodily cavity or wound cavity and then pressed against the mural lining with more or less strength as preferred. For a

staining of any mucosa or tissue surface (or, more properly speaking, the constituents of the tissue) there are three fine tubules soldered into the tube itself and through these the staining solution is introduced. Illumination is derived from a pocket battery (dry cell). Precise adjustment of the apparatus from outside is readily practicable. Animal experimentation over a number of years has provided precise information on the stainability of living cells (and their constituents) as well as on the activity of pharmacologic substances. Thus it is possible to observe details that would not be discernible in a fixed sectional preparation. From use of this method of examining the surface or living tissue, results are forthcoming which apparently take the place of or provide an important supplement to exploratory excision. One may cautiously infer from the report that the new apparatus will make possible early diagnosis of alterations in tissue which is not permitted by the study of fixed sections. One can indeed, by Pick's method, examine the same area of tissue repeatedly without any damage. As staining substances, polychrome methylene blue (of the Unna type) and toluidine blue have proved best thus far. Neutral red and Nile blue are practically without value. Great interest was aroused by the demonstration pictures. Among the visualizations were the filiform papillae of the tongue, the normal portio vaginalis uteri at a magnification of 140 diameters, the vaginal wall in a mild descensus, and normal epithelium of the oral mucosa. Visualizations of normal mucosa are easily interpreted, but interpretation of diseased tissues by the new method is distinctly as yet a thing of the future to be achieved after further experimentation. This means a thorough testing of Pick's apparatus with the largest possible material.

SWITZERLAND

(From Our Regular Correspondent)

March 15, 1937.

Second International Medical Week in Switzerland

The second International Medical Week in Switzerland was held at Lucerne. Attendance was even larger than that at the first Medical Week. The ideal that underlies these gatherings is to assemble the leading scientists from different lands for a discussion of common problems. The Swiss government was again the sponsor, and the sessions were officially opened by its representative. The papers were submitted according to sections. Only the "high spots" of the program can here receive mention.

The first paper, entitled "Drugs That Paralyze the Sympathetic Nerves," was read by Prof. J. A. Gunn of Oxford. Prof. François Rathery of Paris then spoke on "Lipoid Nephrosis and Its Treatment." Prof. Robert Bing of Basle, neurologist, discussed "Somatic Factors in the Etiology of Psychogenic Symptoms." Bing reiterated the objections, which he has constantly raised during the last twenty-five years, to Babinski's theory of hysterical symptoms, a theory that was generally accepted at about the turn of the century. Whereas Babinski disallowed the influence of physiologic factors in the etiology of pathologic psychogenic states, Bing adduces proof that the pattern of a whole group of typical hysterical syndromes is not merely that of an idea inherent in the patient's psyche but instead represents a structural functional development quite like an organic symptom complex. The majority of psychiatrists are today also of the opinion that the mechanism which governs the somatic symptoms in psychoneuroses is to be strictly differentiated from the original motive. The theory upheld by Bing has come to be accepted by nearly all neurologists. According to this theory hysterical "escape into illness" comes about through channels that are bounded by anatomic, physiologic and embryologic factors.

The topics of the second day were "Circulation, Respiration and Tuberculosis." Prof. E. P. Pick, Viennese pharmacologist,

spoke first on "Self-Protection and Regulation in the Circulation." He discussed the great significance of the physical regulation of the heart, the diastolic filling and dilatation, the venous back flow and so on. He called attention to the significance of pericardial regulation in pathologic circumstances; to the blood deposits many times capable of causing occlusion through the blocking of a vein, especially the venous hepatic plexus, which receives a large quantity of blood and is able by diminution of the circulating blood stream to exercise a protective effect like that of a venesection. The second type of defense mechanisms, those which chiefly regulate the circulation through the nervous system, is frequently influenced by chemical stimuli. A third class of protective vascular reactions is based on the cooperation of stimulating and protective chemical substances with the nervous mechanism that regulates circulation and with the discharging reflexes in particular. Prof. W. R. Hess, Zurich physiologist, next discussed "Central Regulation of Circulation and Respiration." If demands are made on the circulatory and respiratory systems by energetic exercise, the sympathetic acts as regulator. The centers that regulate circulation and respiration are located in the medulla oblongata, but the thalamencephalon too exerts notable influence.

BRONCHOSPIROMETRY

Prof. H. C. Jacobaeus of Stockholm then spoke on the subject "Results in Bronchspirometry." Professor Jacobaeus devised the technic of bronchspirometry and he has performed about 200 such operations. By this procedure the size and function (vital capacity, oxygen intake, and carbon dioxide excretion per time unit) of each lung can be gaged. The method is of practical value, especially in bilateral pulmonary tuberculosis. By bronchspirometry the functioning of the diseased lungs can be determined and there is a degree of correspondence between these observations and the results of clinical and roentgen examination. The procedure furthermore makes possible exact evaluations of pulmonary function under pneumothorax and thoracoplasty. Professor von Gröer of Lwów next spoke on "Allergometry in Tuberculosis." Allergometry is a method by which the actual individual allergic condition of the organism in relation to certain allergens, tuberculin for example, can be determined in tuberculous patients. By a repetition of such determinations, corresponding alterations are established and therewith the course of that allergic path which the allergy will follow during infection is determined. Thus is provided a picture of the pathologic processes in tuberculosis which can be supplemented by clinical observations. The value of mathematically exact allergometric observation of tuberculosis lies in the fact that it permits a step by step, quantitative tracing of the pathologic factors in the disease. Consequently the procedure possesses a great importance for differential diagnosis and for prognosis.

Finally Prof. Phillip Schwartz of Istanbul spoke on "The Influence of Allergy on Tuberculosis." Professor Schwartz was able to determine the pathologic substratum of allergic reactions in phthisis. Types of the disease as it occurs in man can be artificially produced and brought under roentgenologic control. This artificially produced disease may be characterized by sudden manifestations as well as almost complete disappearance of tuberculous infiltration. Tuberculous infection elicits the same alterations in children as in adults. Six years after the onset of tuberculosis the immunobiologic effect may cease and a new infection characterized by precisely the same syndrome can be produced. The intra-alveolar accumulations, which are subject to complete dissolution, correspond to the clinically demonstrable infiltrations. This type of reaction is regarded as a result of hypersensitivity. The condition of the blood-cerebrospinal fluid barrier is decisive for the hematogenic dissemination of tuberculous infection. If it is open (as in early childhood, for example) a tuberculous meningitis may develop from hematogenic dissemination. The degree of sensi-

tivity within or without the blood-cerebrospinal fluid barrier can at the same time be distinguished.

The third day was given over to the topic "Metabolism, Hormone and Vitamin." Prof. Albert Szent-Györgyi of Szeged, Hungary, spoke on "Oxidation, Fermentation and Intermediate Metabolism." This scientist, who has become famous through his isolation and identification of vitamin C, has recently studied the mechanism of biologic oxidation. He has obtained an insight into the main process of lactic acid fermentation. Oxalic-acetic acid performs an important catalyzing function in oxidation by acting as an intermediate hydrogen acceptor. The nutritive material is reduced to fumarate by hydrogen and then reduced by the respiratory ferment, the cytochrome being reoxidized to oxalacetate. With respect to carbohydrate in the muscles, respiration and fermentation are identical activities except for this difference, that in fermentation the triose is oxidized by pyruvic acid and in respiration by oxalacetate. The product of oxidation is in either case pyruvic acid. By partial oxidation and polymerization this can be resynthesized into carbohydrate. The regulation of this oxidation is likewise the function of oxalacetate. If the catalytic function of the last named substance is disturbed, only an incomplete oxidation will take place, with decarboxylation to acetone. The study of the respiratory processes has already led to the discovery of many interesting substances (riboflavin, co-dehydroase, civamic acid and so on). Professor Szent-Györgyi, in collaboration with Professor St. Ruzsnyak, a clinician (also of Szeged University), has discovered a new substance in paprika and lemons which apparently is of a vitamin character and which has been called vitamin P. Chemically it is of the flavone group.

Prof. Edward Mellanby of London, then discussed "Degenerative Alterations of the Nervous System Due to Faulty Nutrition." Clinically it is manifest that the impairment of the nervous system in pellagra, convulsive ergotism and lathyrism is a result of defective nutrition. Subacute, funicular myelitis, too, seems to be closely related to the same cause. A disturbance of metabolism underlies all these conditions. Similar degenerative alterations in the nervous system with debilitation of nervous conduction but without inflammatory reaction or hyperplasia of neuroglia can be readily produced in young animals by specific changes in the nutriment. Insufficient intake of carotene and vitamin A, especially in conjunction with increased ingestion of cereals, will elicit typical degenerative nervous impairment with disturbance of coordination in the course of a few months. The parts first to be affected are the ascending nerves of the spinal cord and the afferent peripheral nerves. The addition of a few milligrams of carotene to the daily regimen prevents the manifestation of any degenerative alterations, inhibits the progress of already present impairment and has a definite curative influence on diseased peripheral nerves. The hypertrophy and inflammation of epithelium in xerophthalmia due to vitamin A deficiency are associated with degenerative changes in the cells of the gasserian ganglion and with the weakening of the afferent fibers of the fifth cranial nerve. Xerophthalmia is apparently a terminal result of an impairment of neurotrophic regulation and the same may be said of other types of epithelial hypertrophy and inflammation arising from vitamin A deficiency. Despite the great importance of vitamin B for the nervous system, it cannot be demonstrated experimentally that absence of this vitamin from the diet will be followed by any debilitation of the nerve fibers or of the peripheral fibers (such as is observable in beriberi). The next paper, by Prof. Ferdinand Sauerbruch of Berlin, dealt with "The Surgical Treatment of Certain Types of Endocrine Disorders." The speaker stressed how difficult it is to determine when operation is indicated. Therapeutic concepts that grope blindly still prevail to a great extent in endocrinology. Surgical intervention is most clearly indicated if pathologic and

anatomic glandular alterations can be established with certainty and if the symptoms of illness are in part or wholly traceable to glandular hyperfunction. The favorable results of surgery are more doubtful in hypofunctional states such as myxedema, tetany and Simmonds' disease. The chances of a successful organ transplantation are slight, although instances of success have been reported. Then there is the question of the removal of endocrine organs not in themselves the agents of pathologic change in order to influence certain disease conditions: for example, total extirpation of the thyroid in the treatment of angina pectoris, unilateral adrenalectomy to relieve hypertension in youthful patients, hypophysectomy in diabetes, and parathyroidectomy in generalized bone and joint disease. Sauerbruch discountenances all the foregoing interventions. He is equally skeptical with regard to the denervation of the adrenals and of attempts to ameliorate disease of the heart and lungs by surgical operations on the sympathetic and vagus.

Prof. Hans Guggisberg, Berne gynecologist, discussed "The Hormone Relationship Between Mother and Child." The placenta is, so to speak, the central organ of fetal metabolism and at the same time it gives off specific substances that influence both mother and fetus. The fetus itself forms but little hormone. Its glands of internal secretion become active only toward term. The final speaker of the day was Prof. L. K. Wolff of Utrecht, Netherlands, who discussed "Methods of Determining Vitamin Content in the Blood and Their Significance for the Evaluation of the State of Nutrition in Man." Wolff has undertaken extensive investigations of this problem at the Hygienic Institute, of which he is head. He was able to demonstrate the presence of vitamin A, vitamin C and riboflavin in the liver of about 1,000 cadavers. The vitamin A and vitamin C content in the diet and in the blood of unemployed persons was also reckoned; 25 per cent of these persons were found to be deficient in vitamin A and 10 per cent in vitamin C. The vitamin A and vitamin C values in the blood appeared good indexes of the supply in the entire organism. Vitamin C values in the blood and urine showed a constant ratio.

A special session was this time held at the University Clinic of Zurich. Prof. Felix R. Nager, the first speaker at this session, discussed "The Pathology of the Labyrinthine Capsule." He referred in particular to a biologic peculiarity of this bone and said that the pathogenesis of the typical disease of the capsule of the labyrinth, known as otosclerosis, has yet to be explained. It is not unlikely that precisely by means of comparative studies of labyrinthine disease an understanding of these conditions will be arrived at. Professor Clairmont, surgeon, gave a survey of "The Surgery of Calcium Oxide Metabolism," in which was included a description of its biology, its importance in inflammations and in the healing of wounds, the formation of concretion, in which the parathyroids play a part, and the circumstances of the healing of fractures in joint, muscle and bone diseases. The disturbances of calcium oxide metabolism as a result of parathyroid dysfunction are hyperthyroidism and hypothyroidism; special studies of these conditions have been made at the Zurich surgical clinic. The speaker next discussed the therapeutic values of parathyroidectomy and other surgical measures, besides treatment with parathyroid extract and a viosterol preparation. Administration of calcium is unimportant for the production of hemastasis. Prof. Ernst Albert Gäumann, botanist, described "Problems of Immunity in Plants." This lecture was noteworthy because of the general biologic implications of these questions. Professor Löffler then spoke on "The Pathogenesis of Bronchiectasis." He has learned from extensive investigation that it is certain sections (the bronchus of the left lobe inferioris, the bronchus of the right lobe superioris and the cardiac bronchus) of the bronchial tree and not the pulmonary lobes as such which determine the localization of bronchiectasis. The asymmetry of these areas is striking. The term bronchiectasis implies only

a dilatation; the purulent destruction of the pulmonary parenchyma with or without involvement of the bronchial wall is an abscess condition and not bronchiectasis. Cases of bronchiectasis are frequently combined with other lesions within the lungs (pulmonary cysts, for example) and in other organs. Bronchiectasis is often present in members of the same family. Although it is incontestable that bronchiectasis may be acquired, the congenital form of the disease must be thought of as a possible underlying condition in children who present histories of apparently unimportant colds and mild infections.

Two topics, "Pediatrics" and "Intoxications," were discussed on the fifth day. Professor Frontali of Padua reported his observations of "Hemorrhagic Diatheses in Childhood," emphasizing the significance of the capillaries. He also reviewed the concept of the endothelial constitution and the endothelial syndrome. Professor Péhu of Lyons read a comprehensive paper on "Bone Alterations and Blood Diseases in Childhood." Prof. Wolfgang Heubner of Berlin, spoke on "Chronic Intoxications," with particular reference to the essential nature and above all the significance of the allobiotic effect, an active constituent which continues after the toxin itself has been eliminated. The accumulation of digitalis, for example, is no longer to be explained as a storing of toxin but more reasonably as a typical chronic intoxication. Another important example is chronic arsine poisoning. In chronic intoxication from hydroquinone one can observe a wholly new type of toxic effect; namely, a reversible conversion of black hair into white in experiments performed with cats. Prof. Heinrich Zangger of Zurich spoke on "Intoxications from Volatile Poisons" and described the research he has done on this type of poisoning. Zangger's investigations are of great importance for social and industrial hygiene, as poisoning from volatile substances is a common occupational hazard. Prof. Maurice Roch of Geneva submitted a paper on "The Treatment of Mushroom Poisoning."

On the final day, the lecture of Prof. J. F. Fulton of Yale University had to be canceled, as Professor Fulton was unable to reach Lucerne on account of illness. Prof. Karl Henschen of Basle gave a comprehensive report of his experimental studies of "The Crystalline Structure of the Bones and Its Relation to the Physiology and Pathology of the Skeleton." He is especially interested in the spongy tissues, and his crystallographic observations provide a broader understanding of bone disease. The final speaker was Prof. Pierre Decker of Lausanne, who discussed the present state of the problem of post-operative disturbances. He took up his own study of blood conditions with particular reference to the chlorine content.

The convention was a pronounced success. Three evenings were set aside for informal general discussions and these were attended by large numbers and lasted till midnight. The entire program was again organized by the *Schweizerische medizinische Wochenschrift* of Basle and all arrangements were once more in the capable hands of Prof. Alfred Gigon. The next International Medical Week will be held at Interlaken from Aug. 29 to Sept. 4, 1937.

Marriages

CECIL COLLINS SWANN, Asheville, N. C., to Miss Dorothy Everett Spalding of Montclair, N. J., May 8.

THOMAS PECK BUTCHER, Emporia, Kan., to Miss Freda Allyn Dickey of Kiowa, May 22.

LOUIS CARROLL ROBERTS to Miss Jessie Speight Ward, both of Durham, N. C., April 30.

MYRON L. KENLER to Miss Muriel Nina Marcuse, both of Jamaica, N. Y., May 30.

RICHARD J. KRAEMER to Miss Helen V. Flynn, both of Providence, R. I., April 24.

Deaths

John Henry Wyckoff ☉ New York; University and Bellevue Hospital Medical College, New York, 1907; practiced in New York since 1910; dean and professor of medicine at his alma mater since 1932; member of the Association of American Physicians and the American Clinical and Climatological Association; fellow of the American College of Physicians; past president of the American Heart Association and the Association of American Medical Colleges; chairman of the heart committee and formerly vice president of the New York Tuberculosis and Health Association; member of the medical advisory committee of the advisory board on industrial education, member of the board of administrative consultants of the department of hospitals and of the technical advisory committee on district health administration; was cited "for conspicuous and exceptional service" in France during the World War; director of the third medical division and visiting physician to the Bellevue Hospital; consulting physician to St. Luke's Hospital, Newburgh, N. Y.; St. Joseph's Hospital, Yonkers, N. Y., Good Samaritan Hospital, Suffern, N. Y., Mount Vernon (N. Y.) Hospital, Presbyterian Hospital, Newark, N. J., St. Agnes' Hospital, White Plains, N. Y., St. John's Hospital, Long Island, N. Y., and Southside Hospital, Bayshore, and consulting cardiologist to St. Joseph's Hospital, Far Rockaway, N. Y.; lieutenant colonel in the medical reserve corps of the U. S. Army; trustee of the New York Academy of Medicine, a member of the Technical Board of the Milbank Memorial Fund, and a member of the board of trustees of Rutgers University; aged 55; died, June 1.

Alfred Adler, widely known psychiatrist of Vienna and New York, died, May 28, suddenly in Aberdeen, Scotland, of heart disease, aged 67. Dr. Adler was born in Vienna and received his medical degree at the Medizinische Fakultät der Universität Wien, Austria in 1895, where he also studied philosophy, sociology and psychology. He was the founder of the School of Individual Psychology in Vienna, and was visiting professor of medical psychology at the Long Island College of Medicine in Brooklyn. Among his works that have been translated into English are "The Practice and Theory of Individual Psychology," "Understanding Human Nature," "The Science of Living," "Pattern of Life," "The Neurotic Constitution," "What Life Should Mean to You" and "Study of Organ Inferiority and Its Psychical Compensation." Dr. Adler was the editor of *Internationale Zeitschrift für Individual Psychologie*, and in 1935 founded and was editor of a companion journal in English known as the *International Journal of Individual Psychology*, published in Chicago. At the time of his death, he had been lecturing on psychopathology at Aberdeen University and was to have delivered lectures in Edinburgh, Liverpool, Manchester and London.

Franklin M. Stephens, New York; University of Pennsylvania Department of Medicine, Philadelphia, 1885; member of the Medical Society of the State of New York and the American Otological Society; fellow of the American College of Surgeons; formerly professor of otology at the New York Polyclinic Medical School and Hospital; served in various capacities in the Robert Packer Hospital, Sayre, Pa., and the New York Eye and Ear Infirmary; aged 77; died, May 20, of pneumonia following the amputation of his leg for gangrene.

Reginald St. Elmo Murray, Gardner, Mass.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1913; member of the American Psychiatric Association, the American Association for the Advancement of Science, National Committee for Mental Hygiene and the American Roentgen Ray Society; served with the Canadian Army during the World War; formerly connected with the veterans administration; aged 50; died, March 13, in New York, following an operation for brain tumor.

John Monroe Fisher ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1884; clinical professor of gynecology at his alma mater; fellow of the American College of Surgeons; president of the Aid Association of the Philadelphia County Medical Society; during the World War was a member of the medical advisory board and the medical service corps; on the staffs of the Jefferson Medical College Hospital and St. Agnes Hospital; aged 78; died, May 20.

Elmer Goodman Balsam ☉ Billings, Mont.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; past president of the Montana State Board of Health; secretary of the Medical Association of Montana; on the staffs

of the Billings Deaconess Hospital and St. Vincent's Hospital; aged 52; died suddenly, May 13, in a local hospital of an embolism following a minor knee injury.

John Morton McWharf, Ottawa, Kan.; University of Buffalo School of Medicine, 1868; member of the Kansas Medical Society; a member of the board of trustees of Ottawa University, 1897 to 1912, and vice president of the board, 1909 to 1912; formerly member of the state legislature; aged 94; died, March 20, in the Menorah Hospital, Kansas City, Mo., of carcinoma of the prostate.

Orra Edgar Patterson, Whiterocks, Utah; George Washington University School of Medicine, Washington, D. C., 1908; member of the Utah State Medical Association; served during the World War; for many years connected with the Indian Service; aged 57; died, March 18, in St. Mark's Hospital, Salt Lake City, of coronary occlusion and chronic gall-bladder disease.

Howard R. Keylor, Walla Walla, Wash.; College of Physicians and Surgeons, Baltimore, 1882; member and in 1895 vice president of the Washington State Medical Association; formerly member of the state board of medical examiners, acting as its secretary; for many years overseer of Whitman College; aged 76; died, March 27.

Frank Duane Mower, Newberry, S. C.; Tulane University of Louisiana Medical Department, New Orleans, 1907; member of the South Carolina Medical Association; past president of the Newberry County Medical Society; served during the World War; aged 57; died, March 20, of cardiovascular renal disease.

Archibald Duncan MacLaren, Port Huron, Mich.; Long Island College Hospital, Brooklyn, 1876; member of the Michigan State Medical Society; past president of St. Clair County Medical Society; police commissioner in 1900 and later health commissioner; aged 88; died, March 22, of myocarditis.

Albert Marsh, Newton, Mass.; Albany (N. Y.) Medical College, 1885; member of the Massachusetts Medical Society; assistant in obstetrics at his alma mater from 1886 to 1889 and instructor in obstetrics from 1889 to 1891; aged 77; died, March 17, of coronary thrombosis.

James John McLinden, Waterbury, Conn.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the Connecticut State Medical Society; on the staffs of St. Mary's Hospital and the Waterbury Hospital; aged 60; died, March 16, of pneumonia.

Willard Lloyd McCormick, Bellevue, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1932; member of the Michigan State Medical Society; aged 32; died, March 20, in the Nichols Memorial Hospital, Battle Creek, of pneumonia.

Jefferson Davis, Toccoa, Ga.; Atlanta Medical College, 1884; member of the Medical Association of Georgia; past president of the Stephens County Medical Society; formerly state senator; served during the World War; aged 70; died, March 30.

William Tupper Elliott ☉ Helper, Utah; Northwestern University Medical School, Chicago, 1916; past president of the Carbon County Medical Society; served during the World War; county physician; aged 47; died, March 29, of coronary occlusion.

Frank Clark Myers, Spokane, Wash.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; formerly connected with the Indian Service; aged 83; was found dead, March 20, of myocarditis and arteriosclerosis.

William L. Fisher, Lake Charles, La.; Tulane University of Louisiana Medical Department, New Orleans, 1895; for many years parish coroner; on the staff of St. Patrick's Hospital; aged 71; died, March 7, of cerebral thrombosis.

Joseph Archambault, Fort Kent, Maine; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Que., Canada, 1893; aged 58; died, March 31, of lobar pneumonia and influenza.

Arthur Joseph Parker ☉ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1920; fellow of the American College of Surgeons; on the staff of the Greenpoint Hospital; aged 40; died, March 19.

James Wilburn Macy, Wichita, Kan.; College of Medical Evangelists, Los Angeles, 1936; resident physician to the Sedgwick County Hospital; aged 40; died, March 7, as the result of injuries received in an automobile accident.

Reuben Zimmerman ☉ Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1927; aged 33; on the staff of the Beth Israel Hospital, where he died, March 9, of rheumatic heart disease.

William Henry Connor ♂ Medical Inspector, Commander, U. S. Navy, retired, Coronado, Calif.; Harvard University Medical School, Boston, 1906; entered the navy in 1910 and retired in 1934; aged 56; died, March 21.

Rufus Alonzo Mooror, Georgiana, Ala.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the Medical Association of the State of Alabama; aged 68; died, March 5, in a hospital at Greenville.

Anna Johns Gesler, Narasaravupet Guntur District, Madras Presidency, India; Woman's Medical College of Pennsylvania, Philadelphia, 1926; a medical missionary; aged 41; died, March 13, of ectopic pregnancy.

John Alexander MacFadyen ♂ Worcester, Mass.; University of Vermont College of Medicine, Burlington, 1906; member of the American Urological Association; aged 64; died, March 30, of coronary thrombosis.

John Ramsey McElroy, Newcomerstown, Ohio; University of Wooster Medical Department, Cleveland, 1880; formerly postmaster and member of the board of education; aged 89; died, March 30, of bronchopneumonia.

Edward M. Fleenor, Johnson City, Tenn.; Chattanooga (Tenn.) Medical College, 1898; member of the Tennessee State Medical Association; aged 67; was killed, March 29, in an automobile accident near Augusta, Ga.

Michael Joseph Kelley ♂ Watertown, Mass.; University of the City of New York Medical Department, 1882; member of the school committee and board of health; aged 79; died, March 21, in West Palm Beach, Fla.

John Addy Sponagle, Middleton, N. S., Canada; Halifax Medical College, Halifax, N. S., 1883; served with the Canadian Army during the World War; for two terms mayor of Middleton; aged 76; died, February 19.

David Burt Willson Martin, Ingomar, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1901; aged 66; died, March 14, in St. John's General Hospital, Pittsburgh, of uremia and carcinoma of the prostate.

Willmer Armstrong Latimore, Pittsburgh; Eclectic Medical Institute, Cincinnati, 1897; aged 67; died, March 26, in the Homeopathic Hospital, of pneumococcal meningitis, following influenza and otitis media.

John Wicker Echols, McAlester, Okla.; Kentucky School of Medicine, 1894; formerly prison physician; for many years a member and at one time president of the board of education; aged 65; died, March 22.

Laird O'Neill Miller ♂ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; aged 61; on the staff of the Allegheny General Hospital, where he died, March 18, of bronchopneumonia.

Marshall Edward Chambers, Vinson, Okla.; University of Nashville (Tenn.) Medical Department, 1900; member of the Oklahoma State Medical Association; aged 67; died, March 30, of heart disease.

John Elzo Newland, Center Point, Iowa; Hahnemann Medical College and Hospital, Chicago, 1917; member of the Iowa State Medical Society; aged 43; died, March 13, of carcinoma of the lung.

Harry Levy, Birmingham, Ala.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the Medical Association of the State of Alabama; aged 57; died, March 23.

Benjamin Perry Matheson, Fort Myers, Fla.; Medical College of the State of South Carolina, Charleston, 1890; aged 73; died, March 31, in a hospital at Orlando, of nephritis and arthritis.

William Green Eggleston, Oakland, Calif.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881; aged 77; died, March 29, of pneumonia.

John Leander Fierstone, Long Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; aged 78; died, March 29, of arteriosclerosis and nephritis.

Rufus C. Jones, York, Ala.; Medical College Montezuma University, Bessemer, Ala., 1898; aged 78; died, March 15, in the South Highlands Infirmary, Birmingham, of pneumonia.

Ira Elton Neer, Miami, Fla.; St. Louis University School of Medicine, 1904; served during the World War; aged 61; died, March 30, in a local hospital, of cirrhosis of the liver.

Joseph Levering McCabe, Denver; Medical College of Virginia, Richmond, 1917; connected with the Veterans Administration; aged 44; died in March at Williams, Ariz.

Bertha Frederica Carl Frommell, Orlando, Fla.; Woman's Medical College of Pennsylvania, Philadelphia, 1896; aged 64; died, March 13, of coronary thrombosis.

Anna Law Avard, Scranton, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1894; aged 70; died suddenly, March 29, in Selma, N. C., of heart disease.

Herbert William David Garred, Charleston, W. Va.; University of Maryland School of Medicine, Baltimore, 1928; aged 34; died, March 12, of edema of the brain.

Milber Brink, Boyden, Iowa; Rush Medical College, Chicago, 1884; aged 86; died, March 4, at Estherville, of arteriosclerosis and carcinoma of the esophagus.

John Floyd Pruett ♂ San Francisco; Stanford University School of Medicine, San Francisco, 1914; served during the World War; aged 50; died, March 17.

Marion J. Nicholson, Stephens, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1887; aged 74; died, March 20, of carcinoma of the rectum.

George Watson Fowler, Marengo, Ill.; College of Physicians and Surgeons of Chicago, 1891; aged 85; was found dead in his office, April 13.

Francis Frederick Malone, Los Angeles; Northwestern University Medical School, Chicago, 1904; aged 60; died, March 9, of coronary thrombosis.

Annette E. Lamphear ♂ New York; Woman's Medical College of the New York Infirmary for Women and Children, 1890; aged 72; died, March 27.

Charles Purdy Lindsley ♂ New Haven, Conn.; Yale University School of Medicine, New Haven, 1878; aged 82; died, March 29, of arteriosclerosis.

Matthew Ohaver, Millersburg, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; aged 64; died suddenly, March 26.

Frederick S. Markel, Allenville, Mo.; Marion-Sims College of Medicine, St. Louis, 1892; aged 75; died suddenly, March 16, of heart disease.

William Walter Haven, Granite City, Ill.; Barnes Medical College, St. Louis, 1908 and 1909; aged 58; died, March 29, of cerebral hemorrhage.

James H. Erskine, Oakland, Calif.; Cleveland Homeopathic Medical College, 1898; aged 77; died, March 29, of chronic myocarditis.

George Willment Forester, Santa Ana, Calif.; Drake University Medical Department, Des Moines, Iowa, 1894; aged 73; died, March 28.

Thomas Popham McCullough, Peterborough, Ont., Canada; Trinity Medical College, Toronto, 1888; aged 77; died, March 18.

Alexander McLeod, Wroxeter, Ont.; Canada; McGill University Faculty of Medicine, Montreal, Que., 1914; aged 54; died, March 4.

Colon Beck, Clyde, Ohio; Eclectic Medical Institute, Cincinnati, 1897; aged 66; died, March 31, of uremia and cerebral hemorrhage.

Walter Jackson Coleman, Mineola, Texas; Medical College of Alabama, Mobile, 1888; aged 76; died, March 28, of myocarditis.

William Milton Mather, Tweed, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1886; aged 78; died, March 16.

J. Frank Harris, Sarasota, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1884; aged 80; died, March 28.

Ralph Robert Barker, Jasper, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1910; aged 50; died, March 20.

John Boggs Garrison, Hopewell, N. J.; New York Homeopathic Medical College, New York, 1882; aged 88; died, May 19.

Eber Whitney Gurley, Cleveland; Cleveland Homeopathic Medical College, 1898; aged 61; died, March 2, in Long Beach, Calif.

Ruce Marion Miller, Ivyton, Ky. (limited license in Kentucky, year unknown); aged 78; died suddenly, March 22.

Edward Lowell MacNamara, Syracuse, N. Y.; Syracuse University College of Medicine, 1897; aged 62; died, March 17.

Frank T. Eisenman, Los Angeles; Louisville (Ky.) Medical College, 1888; aged 75; died, March 12.

Bureau of Investigation

DR. H. WILL ELDERS

The Federal Trade Commission Orders Elders' Message to Yearning, Childless Females Modified

The Federal Trade Commission, under date of April 5, 1937, ordered H. Will Elders, his representatives, agents and employees, to cease and desist from representing either directly, indirectly or by implication, endorsements or testimonials of others, that "Dr. H. Will Elders' Filled Prescription for Women," "Dr. H. Will Elders' Private Prescription Sanitary Douche" and "Dr. Elders' Laxative Lozenges" constitute a cure, remedy or competent and adequate treatment for sterility in women.

According to the biographic files of the American Medical Association, H. Will Elders of St. Joseph, Mo., was born in 1874 and was graduated in 1894 from the American Medical College of St. Louis, a school which is now extinct. Elders was licensed in Missouri in 1894.

Typical advertisement of Elders' "sterility cure."

H. W. Elders has been in the mail order "patent medicine" business for a great many years. In 1911 Dr. Elders was advertising in the *Police Gazette* a "boon" for banishing all forms of the tobacco habit in from 72 to 120 hours. An analysis by the government chemists at that time showed that the "boon" consisted essentially of cocaine derivatives, strychnine and cinchona alkaloids. As the tablets were not a specific for the tobacco habit and as they did contain "injurious drugs or ingredients," the product was declared misbranded by the Food and Drug Administration in 1911. Elders pleaded guilty and was fined \$100 and costs.

In 1924 Dr. Elder was offering to childless women through paid advertisements in the daily press a free copy of a "new book" by Dr. H. Will Elders. In addition to the "free book," the doctor had a "wonderful" aid for "every woman who wants to live a normal, happy home life with little ones around her." This "wonderful" aid was "Steriltone." In February 1935 this product was declared by the Food and Drug Administration to be sold under fraudulent therapeutic claims. The composition, according to the government report, was essentially plant drug extracts, including hydrastis and a laxative, with ferrous sulfate and arsenic trioxide. Another Elders nostrum that was the subject of a Food and Drug Administration Notice of Judgment was the "Female Re-Lax Lozenges."

Elders advertises his "patent medicines" by means of magazines, newspapers and circular letters. Typical of the Elders advertising methods is a large, four-page sheet distributed to childless women in 1936 and bearing the heading: "A Message of Joy to Every Woman Who Yearns for a Baby or Two of Her Own!" Under the banner heading is a picture of a mother with an infant at the breast. There is also a likeness of Dr. H. Will Elders, seated at a desk with pen in hand, apparently about to dash off one of his treatises on "Common Causes of Functional Sterility."

Elders sends to inquiring women two booklets "in plain wrapper." In the booklets Elders claims to "discuss many important subjects relating to the female sex. . . . They tell how you too may combat your troubles as thousands of others have. . . ." In the circular letters Elders mixes romantic biography, descriptive of his practice "in the picturesque Ozark country," with paragraphs exalting Dr. Elders. "I long ago realized that few physicians were competent to successfully treat ailments peculiar to the so-called weaker sex, and I decided to make this my life work and study. . . ."

Most ingenious was the Elders explanation of sterility. "In general, I want to say to you that in my experience treating women for this condition, the majority of cases are due to the closing of the fallopian tubes . . . blowing air or gas through them does not reach the ovaries and therefore could not get at the cause."

It is safe to say that few physicians would agree with the Elders idea of competence as expressed in Dr. H. Will Elders' Filled Prescription for Women. The quantitative formula per tablet, as given in the Federal Trade Commission's Docket No. 2673, is as follows:

Powdered Viburnum Opulus.....	1/2 grain
Powdered Gentian.....	1 grain
Powdered Ferrous Sulfate—Dried.....	1 grain
Arsenous Acid.....	1/60 grain
P. E. Cascara Sagrada.....	1/2 grain
Powdered Hydrastis.....	1 grain
Powdered Aletris.....	1 grain
Powdered Caulophyllum.....	1 1/2 grain
Powdered Pulsatilla.....	1 grain
Powdered Cimicifuga.....	1 grain
Desiccated Corpus Lutea (Sow).....	1/2 grain

The quantitative formula per tablet for Dr. Elders' Laxative Lozenges is given as:

Cascarin.....	1/4 grain
Aloin.....	1/4 grain
Podophyllum Resin (U. S. P.).....	1/6 grain
Strychnine Sulfate.....	1/60 grain
Ext. Belladonna Leaves.....	1/6 grain
Oleoresin Ginger.....	1/8 minim

The formula for Dr. H. Will Elders' Private Prescription Sanitary Douche, based on a quantity of 101 pounds, is as follows:

Borate Tetra.....	100 lbs.
Chloramine-T.....	500 grms.
Menthol Crystals.....	260 grs.

The Federal Trade Commission further points out that Elders' medicines, "when used either together or singly, do not constitute a cure, remedy or competent and adequate treatment for sterility in women, nor for diseased conditions which are most frequently the cause of sterility. In cases of sterility due to disease or to anatomical abnormalities, such medicines would not be effective in removing the condition. Neither do said medicines used together or singly constitute a cure, remedy or competent and adequate treatment for female diseases or for leukorrhea or for delayed, suppressed or painful menstruation, nor are they effective in the treatment of such conditions and diseases where the same are caused by many diseased conditions. Representations to the contrary are neither accurate nor limited enough to express the true therapeutic effects of said medicines. . . . The representations of respondent, as aforesaid, have had and do have the tendency and capacity to confuse, mislead and deceive members of the public. . . ."

The Federal Trade Commission has ordered the respondent to file with the commission within sixty days a report in writing, setting forth in detail the manner and form in which he has complied with the cease and desist order. It will be interesting to note his future messages.

Correspondence

RELATION OF AMERICAN MEDICAL ASSOCIATION TO CERTIFICATION OF SPECIALISTS

To the Editor:—Dr. Paul C. Bucy of the University of Chicago has written to THE JOURNAL (May 29) criticizing certain portions of the address of Dr. C. Gordon Heyd on the "Relation of American Medical Association to Certification of Specialists" (THE JOURNAL, March 27, p. 1017).

Dr. Heyd, in spite of his multitudinous duties as President of the American Medical Association, informed himself accurately by correspondence and personal interviews about his subject before he prepared this address. Dr. Bucy, on the other hand, has made no such effort. No communication or enquiry has been received from him at the office of the Advisory Board for Medical Specialties (the coordinating board of all the special certifying boards), nor have the secretaries of the three boards specifically and critically referred to by him been asked whether the sweeping deductions he has drawn are based on fact.

For example, in speaking of multiple certification, or the certification of the same man by more than one board, he assumes that this is not permitted and argues at length that the American Boards of Ophthalmology and of Otolaryngology, which he mentions, ought to be willing to certify in both of these related specialties any man who can qualify. If he had enquired he would have learned that many such men now hold certificates from both of these boards and that others qualified may obtain them in the future. Moreover, it happens that a diplomate of the American Board of Obstetrics and Gynecology, a gynecologist who is an authority on radiation treatment of cancer, is even a member of the American Board of Radiology, serving as one of its examiners.

The sense of Dr. Heyd's remarks on this subject is that as a general procedure multiple certification is undesirable. A man cannot be a "specialist" in too many lines of work. Action taken on this matter at a meeting of the Advisory Board for Medical Specialties was that as a general principle multiple certification was "not viewed with favor." It has never been prohibited and is always left to the individual boards to decide whether the closeness of relationship in any given instance warrants permitting it.

Dr. Bucy speaks of the requirement by some boards that men to be certified must limit their practice to their specialty. He postulates from this that an individual certified as a gastro-enterologist would not be permitted to treat a man with coronary disease who came to him as a sufferer from indigestion.

In the first place, there is no board in gastro-enterology. Men specializing in this work are to be certified basically by the American Board of Internal Medicine with a special examination and certificate issued by that board in gastro-enterology. Dr. Bucy's assumption that such a man would be restricted in his activities is entirely groundless. It is probable that neurosurgery (Dr. Bucy's specialty) will come under a similar plan of action by the recently created American Board of Surgery.

He says further that the purpose of these boards "must be to certify that a given individual is a competent practitioner in a special field." In a broad way this might be desirable, but for the present at least the purpose of these boards is to determine the competence of men who claim to be specialists, not merely practitioners, in these several fields. The public has suffered too long from too many self-styled specialists, and these boards are trying to make available the facts regarding those who are qualified for the claims they may have been making. Later, it may perhaps be advisable to undertake to distinguish and list those who have made themselves "proficient"

to a greater degree than usual but who are not actually specializing in the various branches. Clearly the time is not ripe for this as yet.

Moreover, certain of the boards do not, for definite reasons, require a rigid limitation of work to their specialty, but Dr. Bucy does not seem to be aware of this.

He "differs sharply" with Dr. Heyd on the point that "research work should not be a part of the examination of a candidate for examination." I think his reaction is again due to a misunderstanding of intent. Creditable research work and publications count high in a candidate's favor in the eyes of the boards. Nevertheless many, many well qualified specialists have published little or nothing. They should not be and are not excluded on this account.

Finally, to clinch his argument, after being given an opportunity by THE JOURNAL to review Dr. Heyd's reply, he quotes from the booklet of the American Board of Obstetrics and Gynecology, which does require its candidates and diplomates to limit their work to obstetrics and gynecology. However, he does not quote the broad latitude of practice allowed in this board's definition of the specialty. Nevertheless, it is quite correct, as he says, that this board has ruled "physicians who accept male patients in their . . . practice . . . cannot be regarded as specialists in obstetrics and gynecology." There is an American Board of Surgery for these men if they are qualified, but there are other strong reasons for this rigid attitude.

The criticism is constantly being hurled at the medical profession of this country that our maternal mortality rates are much too high. In the survey of the New York Academy of Medicine it was found that fatal cesarean sections had been done by men listing themselves in the local medical directory of New York County as being "specialists" in proctology, laryngology, roentgenology and, in several instances, general surgery. It is my recollection that one of these fatal operations was performed by an "ophthalmologist."

What sort of specialists are these! Obviously, they are of the type best described as "specializing in the skin and all of its contents"! Can this board hope to correct such a situation if it does not clean house itself, by requiring its diplomates not to do general surgery? It is particularly unnecessary for these men to accept male patients. More important still, they are usually not qualified to undertake, for example, thyroid surgery, as does one gynecologist whom I know.

Obstetrics and gynecology, as a specialty, is certainly a broad enough field to occupy all the attention of any but a superman, if he is to do the best work possible in this specialty.

Until these men demonstrate that they recognize their limitations, always for the benefit of the patient, by not invading other general fields, how can it be expected that others, less qualified in this important specialty, will cease their activities such as were disclosed by the survey quoted?

PAUL TITUS, M.D., Pittsburgh.

Secretary of the Advisory Board for Medical Specialties, and Secretary of the American Board of Obstetrics and Gynecology.

MORTALITY FROM CESAREAN SECTION

To the Editor:—I am in no way qualified to judge whether Dr. D. L. Smith (THE JOURNAL, April 17) is right or wrong in his contention that low cervical cesarean section is preferable to the classic operation; but any one accustomed to weighing evidence may quarrel with his statement of the case. His table 2, for example, reports a total of three deaths out of 100 patients subjected to the low cervical operation and eight deaths out of 180 treated in the classic manner. Application of an elementary test (chi square for a fourfold table) shows that the apparent difference between these mortality ratios

might very easily arise by chance alone. The apparent improvement, in the same table, from 1934 to 1935 is equally devoid of significance. Nor do I think one should speak of a 33½ per cent mortality in a group of six cases and compare this with other mortality rates. I am glad to acknowledge that Dr. Smith's table 5 is, in itself, convincing; but it is surely not unreasonable to ask that contributors of wholly statistical articles should display some knowledge of the elementary principles of statistics.

DAVID L. THOMSON, PH.D., Montreal.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EFFECTS OF TEAR GAS

To the Editor:—I have a case about which I would appreciate your giving me what information you have. It deals with tear gas, and as we have but little contact with tear gas in this country, and I have no recent literature on it, I am unable to form a definite opinion on the matter. The case is as follows: Mr. A was sprayed with tear gas, whether in a closed room or in the open air I do not know. He was taken to a hotel and placed in one of the rooms. In getting him into the room there was some scuffling, and in this scuffling Mr. B brushed his face across Mr. A's sweater. Mr. B stated that he felt moisture on Mr. A's sweater, which was transferred to his face, and that he immediately began sneezing and his eyes began to water. Nine days later Mr. B consulted a physician and stated that he was still having considerable irritation in the nose. Examination by the physician apparently made him feel that Mr. B had a sinusitis and otitis media, as it was these conditions which he reported to the industrial accident commission, the claim being that in the performance of Mr. B's work he came in contact with an irritating toxic substance, which produced the sinusitis and otitis media. The questions I would appreciate your answering are: 1. Would the concentration of tear gas on Mr. A's sweater be sufficient to produce an irritation of Mr. B's nose and eyes, in view of the fact that Mr. B's face only brushed across Mr. A's sweater, and bearing in mind that at no time was Mr. B in the room filled with tear gas, nor was tear gas shot at him? 2. Granted that Mr. B could have had an immediate irritation from the tear gas, would such a slight contact with the tear gas cause a continued irritation for nine days? 3. Is it possible for tear gas, however concentrated, to produce sinusitis and otitis media? 4. Could the mild concentration of tear gas that Mr. B may have gotten be able to produce a sinusitis and otitis media? Frankly, the whole claim seems to me to be so far fetched as to be fantastic. It does not appear reasonable to my mind that an otitis media could develop from tear gas, and it appears highly improbable that a sinusitis could be developed from tear gas. In both instances, however concentrated, and all the more so in this particular case when, if the tear gas did have any effect on Mr. B it would of necessity through the contact have been mild, I even doubt that he could reasonably have had a mild nasal irritation. However, as I have had no experience with tear gas and I have no authoritative literature, I would appreciate your opinion and also any literature which would throw light on this particular case. ROBERT M. COATS, M.D., Weiser, Idaho.

ANSWER.—This query fails to mention the particular type of lacrimatory gas involved. In this country it is believed that police departments rely chiefly on the tear producing agent chloroacetophenone. There are many other lacrimators, such as benzyl bromide, xylol bromide, benzyl chloride, bromo-ketone, di-bromo-ketone, bromo-acetone, dibromo-acetone, bromoacetophenone, chloro-acetone, dichloromethyl ester, chlorosulfonic acid, methylichlorosulfonate, phenyl-carbarylamine chloride, acrolein, stannic chloride, bromoacetic ether and iodoacetic ether. Because of the widespread availability of chloroacetophenone, it is reasonable to believe that this is the substance employed in the present instance. Following are references on the chemistry and toxicology of this substance: Gibson, A., *Mil. Surgeon* 67:195 (Aug.) 1930; McNally, W. D., *J. A. M. A.* 98:45 (Jan. 2) 1932; Tear Gas—Chloroacetophenone, Query and Minor Note, *ibid.* p. 1105 (March 26) 1932; Muntz, Otto, *Leitfaden der Pathologie und Therapie der Kampfstoferkrankungen*, Leipzig: Georg Thieme, 1935; Hanslian, Rudolf, editor, *Der chemische Krieg*, Vol. I, Berlin, E. S. Mittler & Sohn, 1937.

The formula of chloroacetophenone is $\text{C}_6\text{H}_5\text{COCH}_2\text{Cl}$. It is a gray or white crystalline solid with an aromatic odor similar to that of locust blossoms. It is used in gun shells, the Stokes mortar, candles, grenades, air bombs and as a spray when dissolved in organic solvents such as ethyl acetate, or a mixture of benzene and carbon tetrachloride. It may also be mixed

with smokeless powder and magnesium oxide; on burning, this mixture gives off finely divided chloroacetophenone as a white, blue-gray or colorless vapor. It is insoluble in water and has no action on metals. It is neutralized or destroyed by hot sodium carbonate solution and may be removed from the skin with a solution of sodium sulfite in 50 per cent alcohol or with plain alcohol or glycerin. McNally recommends a 0.4 per cent solution of sodium sulfite in a mixture of glycerin 75 per cent and water 25 per cent for use in the eyes. Boric acid solution may also be employed in the eyes although chloroacetophenone is not soluble in it. Alkaline eye ointments have been recommended in German reports, but formulas are not given.

Chloroacetophenone is irritating to the eyes, exposed mucous membranes and skin in very small quantities. Lacrimation begins with a concentration of 0.3 to 0.5 mg. per cubic meter of air. Irritation of the nose occurs with 1 mg. per cubic meter; with 2 mg. per cubic meter use of the eyes is impossible owing to pain and flow of tears. At the latter concentration, irritation of the skin of the face and of the pharynx occurs. The highest concentration which a normal man can tolerate for one minute is 4 to 5 mg. per cubic meter. It is apparent that with a concentration of only a few milligrams in 1,000,000 cubic centimeters of air, the amount necessary to cause severe irritation of eyes, nose, pharynx and skin must be very small indeed, probably not more than a few thousandths of a milligram. As chloroacetophenone is a solid, considerable quantities might remain impregnated in and spread on clothing, particularly if the material were sprayed in solution. A person who brushed his face against cloth so impregnated could easily pick up enough chloroacetophenone to cause severe irritation; and as expressed in a Query and Minor Note in THE JOURNAL already cited, "It is reasonable to believe that enough irritation of the eyes or throat may be produced by tear gases to pave the way for secondary bacterial invasion, with ensuing pharyngitis and conjunctivitis on occasion." The possibility of the production of sinusitis and otitis media secondary to irritation by chloroacetophenone is not at all "fantastic." Chloroacetophenone is not the practically harmless substance it is commonly reputed to be. With direct contact it can cause permanent corneal opacity and resultant blindness, as in one of the cases reported by McNally. It frequently causes more than temporary interference with vision which may take several days to clear up.

PNEUMOTHORAX IN MINIMAL TUBERCULOSIS

To the Editor:—Have you any statistics to show which patients with definitely diagnosed minimal tuberculosis (pulmonary) do better; if first placed on bed rest treatment, or at once started off on artificial pneumothorax? What is the consensus with regard to these minimal cases of pulmonary tuberculosis? Has it swung away from bed rest first and gone to the more radical treatment with artificial pneumothorax treatment or is the latter not considered radical any more? Kindly also state what the indications are for thoracoplasty? Kindly omit name and address.

M.D., Massachusetts.

ANSWER.—Until recent years only a small percentage of patients with pulmonary disease had their lesions detected while in the minimal stage. Moreover, artificial pneumothorax was not thought to be indicated except in the presence of cavities, extensive disease and hemorrhage. Therefore not many reports presenting results of artificial pneumothorax in minimal pulmonary tuberculosis have been made. There are still a number of tuberculosis workers who have not employed artificial pneumothorax in the treatment of minimal disease and who strongly oppose its use. There are others who have employed it and after a sufficient period of observation of their patients strongly recommend it for all progressive minimal lesions. Turner and Collins of Chicago (*Ann. Rev. Tuberc.*, December 1936) made observations on patients with minimal pulmonary tuberculosis treated by various methods and found "that the watchful waiting policy for evidence of progression proved costly and dangerous in several cases, and even fatal in a few. Therefore, we advocate immediate induction of artificial pneumothorax in definitely diagnosed minimal cases." These authors have not seen a "minimal pneumothorax case show progression of the disease in the treated lung or metastasis to a new lobe or exhibit an exacerbation of a previously existing lesion in the contralateral lung." After a careful study of 139 patients with minimal disease treated by various methods, they conclude: "The operative risk in minimal cases is negligible. Percentage of cases with free space is high in minimal cases. The high percentage of effective collapses in minimal pneumothorax cases is a guaranty of good results. Complications were so infrequent that they should not constitute a deterrent for the use of pneumothorax in early cases. The conversion of sputum in positive minimal cases is prompt and certain under pneumothorax treatment. The conversion time, hospital stay and total

disability were definitely decreased by the use of pneumothorax. Pregnancy in minimal cases is well tolerated if supported by pneumothorax. (Four of the cases receiving pneumothorax carried a pregnancy to term without any apparent ill effects.) The conservative treatment of minimal pulmonary tuberculosis requires the early induction of artificial pneumothorax. We believe that the existence of a minimal tuberculous lesion in an individual of "teen" age is an absolute indication for artificial pneumothorax without delay."

Myers and Levine (*Am. Rev. Tuberc.* 31:518 [May] 1935) reported fifty-two cases of pulmonary tuberculosis in which the treatment was instituted while the disease was minimal. In these patients, however, the disease was determined to be definitely progressive before treatment was instituted. Of the fifty-two patients, only three were found to have adhesions sufficiently extensive to interfere with the collapse. At the time the report was made, forty-two of the group were working or ready to work. Four had died, one of whom had miliary tuberculosis, another multiple lesions in various parts of the body, and the other two died of nontuberculous conditions. The results in this group of cases were "superior to those in other groups under our care, that had artificial pneumothorax instituted after the disease had become moderately or far advanced. They are also superior to those of other groups of minimal cases which we have observed on bed-rest treatment alone."

Since many of the reports on artificial pneumothorax therapy have come from institutions where patients have been given long periods of bed rest in addition to collapse therapy, it has been difficult to determine how much credit for the success obtained should be given bed rest and how much to collapse therapy. However, there are now groups of cases on record in which treatment was limited to sanatorium treatment or strict bed rest without the use of collapse therapy. For example, Wherrett (*Am. Rev. Tuberc.* 31:62 [Jan.] 1935) observed for periods of from one to thirteen years 291 patients with minimal tuberculosis, who had only sanatorium treatment. In 28 per cent the results were not good. Pope (*New England J. Med.* 209:765 [Oct. 19] 1933) has reported thirty-four cases in the "teen" age period in which the patients had minimal disease when admitted to the sanatorium. From four to seven years later, 40 per cent were dead.

Thus, it appears that artificial pneumothorax has a definite place in the treatment of progressive, minimal pulmonary tuberculosis. While the patient is lying in bed apparently doing well from the standpoint of absence of symptoms or even gaining in weight, the lesion may progress. Moreover, lesions may appear in the previously good lung while the patient is on strict bed rest. Since collapse of the diseased area definitely inhibits the proliferation of tubercle bacilli and stimulates the formation of scar tissue, it seems logical to bring about these two desired results at the earliest possible moment. Moreover, if the lesion has not yet broken down so that tubercle bacilli are being eliminated, one may prevent this occurrence. On the other hand, if the lesion has already broken down and tubercle bacilli are present in the sputum, artificial pneumothorax in most minimal cases quickly closes the lesion, so that the sputum becomes negative and then completely disappears. Obviously, it is better to treat a tuberculous process by artificial pneumothorax before cavities and adhesions have formed, before large volumes of lung tissue have been involved, and before the patient's general health has become undermined, than to wait until these conditions have developed.

Artificial pneumothorax should not be considered a radical procedure. Indeed, it has become a standard form of treatment. It is not as radical or as drastic as a long period of strict bed rest which takes the patient out of all activities of life, frequently causes him to lose his position, opportunities for promotion or even his entire possessions, and returns him to the world in a mental state that is more difficult to treat than the original disease. The patient with advanced bilateral tuberculosis must be treated in this drastic manner largely because of the contagiousness of his disease. He and society must suffer the consequences, but this is not true of the patient with minimal tuberculosis. Therefore the present campaign which emphasizes the detection of minimal tuberculosis in the lungs of apparently healthy persons and immediate treatment of all such lesions found to be progressive offers the only practical solution of tuberculosis control in the human family.

The patients for whom extrapleural thoracoplasty are now indicated are as follows: 1. Those with moderately or far advanced disease of the proliferative type in one lung who have been observed over a considerable period and for whom attempts at artificial pneumothorax have repeatedly failed, that is, the entire pleural space has been obliterated, frequently give histories of having had pleurisy with effusion at some previous

time. Moreover, temporary interruption of the phrenic nerve should have been attempted and found wanting. 2. When the disease is of the exudative type and the patient is somewhat toxic, one should depend on bed rest and as much immobilization as possible through temporary interruption of the phrenic nerve until the toxemia disappears and the lesion appears to have stopped progressing before attempting extrapleural thoracoplasty. This group includes also patients with less extensive disease but with conditions otherwise the same as the foregoing but who have recurrent pulmonary hemorrhages or who have positive sputum. 3. For patients with disease similar in extent and nature to the foregoing and in whom partial artificial pneumothorax has been accomplished, but after a period of observation it is evident that adhesions will prevent adequate collapse of the diseased lung or that the walls of cavities are so thick and the fibrous tissue in the lesions so dense that pneumothorax cannot result in satisfactory collapse, it is futile to continue with artificial pneumothorax. This procedure should be discontinued and extrapleural thoracoplasty performed at once. 4. Fourth are patients who have been treated successfully by artificial pneumothorax for a time but who have voluntarily given up the treatment before the disease is well under control so that adhesions have formed, or patients who have lost the pleural space through the formation of oblitative adhesions and the disease has become reactivated or cavities have reopened. 5. For patients who have had an extensively diseased lung collapsed by artificial pneumothorax which fails to reexpand when the treatment is terminated, while constituting a very small percentage of patients treated by artificial pneumothorax, it is advisable to continue their refills or perform extrapleural thoracoplasty. 6. Sixth are patients who have been on artificial pneumothorax treatment but have had pleural pulmonary fistulas develop resulting in mixed infection empyemas. Tuberculous empyemas without the presence of fistulas usually do not require surgery, since they may be treated successfully by other methods, such as oleothorax. However, there is the occasional obstinate case in which thoracoplasty must be performed. 7. Some patients who have bilateral apical lesions with cavities, with the upper portion of the lung adherent to the chest wall, may now be treated successfully by partial bilateral thoracoplasty, to close the cavities and adequately collapse the diseased areas.

TREATMENT OF STRONGYLOIDES INFESTATION

To the Editor:—A man, aged 40, who came to me recently, was put in the hospital for an emergency appendectomy four months ago. After the routine laboratory work was done it was found that he had an infestation of *Strongyloides intestinalis*. He dates his present illness to beginning about seven years ago, when he had indefinite pains over the abdomen. Increasing constipation occurred, together with hemorrhoids and a fistula. During this time he also developed a prostatic discharge, which was persistent and annoying. Smears and cultures done by several good urologists were negative. In the past four months he has had three courses of hexylresorcinol crystals, a course of santalin, and numerous other antihelminthics. Nov. 14, 1936, the stools were still strongly positive. Since the treatment was begun, the constipation has cleared up and the prostatic discharge has entirely stopped. The patient feels better physically but is extremely restless and is unable to sleep. Please advise me whether there is some new drug which would clear up this stubborn infestation. Any suggestions you have to offer will be greatly appreciated. Please omit name.

M.D., Florida.

ANSWER.—The peculiar life cycle of *Strongyloides* and its ability to perpetuate itself in the human body (Fülleborn) make it extremely difficult to eradicate. The worms are deeply embedded in the mucosa, although some are near the surface or free in the lumen of the upper small intestine. Most antihelminthic drugs are useless for the embedded worms, just as in the case of *Trichina*. It is probable that pathogenicity is proportional to mass of infection and general condition of the host. In the great majority of infested patients, *Strongyloides* does not produce symptoms. In the case under discussion, it is doubtful whether the worm had any relation to the symptomatology or pathologic changes. It is possible that the hemorrhoids and the anal condition may have resulted from anal invasion of developing larvae. If such was the case, eosinophilia and allergic bronchial or other symptoms might have been associated. The matter could have been settled only by examination of removed hemorrhoids or scrapings of fistulous tracts for larvae. In the absence of diarrhea, one must assume that otherwise the worms played no part in the pathologic condition and symptoms described.

The usual drugs are quite without effect on *Strongyloides* and the infestation has usually been considered incurable. If it should seem wise to treat the patient further for *Strongylus*, it would be advisable to use De Langen's combined method, giving antimony and potassium tartrate and gentian violet

simultaneously. Gentian violet can be administered in doses of from 0.06 to 0.2 Gm. by mouth in pills freshly coated with melted phenyl salicylate three times daily for three to five days in each course. Antimony and potassium tartrate is given intravenously in 2 per cent solution in double distilled water, with care to have the solution perfectly clear. Injections should start with 1 cc. and be increased progressively to a maximum of 6 cc. and a total of twenty injections, given two or three times weekly. The urine should be watched and the treatment discontinued temporarily in case of reaction. The commoner reactions are shown by aching general pains, nausea and vomiting, or a cough. The entire combined procedure may be repeated after a few weeks intermission.

CHRONIC LUMBOSACRAL OR SACRO-ILIAC SPRAINS

To the Editor:—A married woman, aged 30, complains of lower back pain and stiffness in the region of the right sacro-iliac joint, radiating down the right leg to the ankle. There is no other joint pain or fever. The symptoms are of a year's duration and began shortly after a slight strain of the back due to a fall. General physical and serologic examinations are negative except for a deviated septum, large buried tonsils and a posterior drip. Reports of three orthopedic consultants are as follows: 1. Sacro-iliac sprain, x-ray examinations negative. 2. Tilt of the lumbar spine to the left, x-ray examination showing sacralization of the last lumbar vertebra with tilt of the fifth lumbar vertebra to the left. Impression is sciatic scoliosis secondary to a congenital anomaly, with osteo-arthritis of the lower part of the spine and the sacro-iliac joints. Immobilization advised in a double plaster spica followed by a spinal brace. If not relieved, a spinal fusion. 3. A lumbosacral angle of 28 degrees. The fifth lumbar vertebra displaced anteriorly on the first sacral. Tenderness over the right posterior iliac spine. Ober's test 1 plus bilateral. Impression is spondylolisthesis and a spine fusion, fourth lumbar to first sacral, advised: Please suggest further steps in diagnosis and treatment.

B. E. LANDESS, M.D., Ozone Park, N. Y.

ANSWER.—The symptom complex of chronic sciatic nerve pain associated with pain in the lower part of the back, coming on simultaneously to or immediately following an injury in which the back was subjected to acute or sudden strain, is compatible with a diagnosis of chronic lumbosacral or sacro-iliac sprain. The absence of any changes in the bones at the sacro-iliac joint that could be demonstrated in the roentgenogram, and absence of disability in the joints of the extremities, tend to rule out arthritis as an etiologic factor.

Associated with unilateral sacro-iliac pain there is commonly a protective muscle spasm, particularly of the sacrospinalis muscles, which produces a functional scoliosis such as that described for this patient. The sacralization of the last lumbar vertebra, described by one of the consultants, may have been a predisposing factor. Since only one of the three consultants diagnosed displacement of the fifth lumbar vertebra anteriorly on the first sacral, the definite presence of spondylolisthesis would seem not to have been adequately established. This point should certainly be settled, if necessary by taking additional lateral roentgenograms. The slightest rotation of the spine on taking the lateral film may cause a distortion of the shadows of the fifth lumbar and first sacral vertebrae, producing an erroneous impression of displacement. It would be necessary to demonstrate in the roentgenogram a defect in one or more of the pedicles in order to justify the diagnosis. Without having the opportunity of viewing the roentgenograms or of examining the patient to attempt to localize the lesion definitely, one would be presumptuous to advance any opinion. Before treatment is undertaken, organic neurologic lesions should be carefully ruled out.

Conservative measures of treatment should be carried out before operation is considered. Since Ober's test was reported as 1 plus bilateral, it would be advisable that the patient be given gas anesthesia and that both legs be manipulated according to the technic of the late Dr. William Baer. A double plaster spica cast should then be applied, including both legs and the feet and reaching well above the rib region on the trunk. A large window can be safely made over the abdomen. This adds to the comfort of the patient and prevents to some extent the abdominal distention which is so common following application of casts of this type. Immobilization in this cast should be continued for at least three weeks, and preferably for six weeks. A brace should be worn for at least six months if the patient remains free from symptoms. If, however, the patient continues to have pain after the second week in the plaster spica or if the pain returns later while she is wearing the back brace, a fusion operation should be considered.

Physical therapy, including exercises for strengthening the abdominal muscles and the gluteal muscles, should be used after removal of the cast. Permanent cures have been reported in from 75 to 90 per cent of all patients so treated.

IDIOSYNCRASY AND ASTHMA

To the Editor:—Kindly discuss the possibility of an idiosyncrasy to the medication in the following case: A woman, aged 74, weighing about 100 pounds (45 Kg.), always in good health except for symptoms of asthma to a moderate degree during the past several years, developed a slight cold. The cold had been present for two or three days, but the patient had been up and about her regular household duties. On the last day she had a cough and it was decided by members of the household that a medicine for the cough should be obtained. A bottle of cheracol was purchased with directions for one teaspoonful to be given every two hours. A dose of this was given at 7 p. m., and at about 8 o'clock the patient began to have severe dyspnea because of bronchial râles. She had been sitting reading the paper and visiting but asked to be placed in bed at this time. At about 8:10 the doctor was called. The patient was found profoundly dyspneic and cyanotic. She had a pulse rate of 120, which was regular and of good quality, and a temperature of 101.6. The coarse bronchial râles obscured other breath sounds and little was learned on percussion of the chest. There was slight abdominal distention. The patient frantically asked to be moved back to her chair. This was done. Steam inhalation with tincture of benzoïn compound was started, and drops of dl-1-phenyl-2-aminopropanol-1-hydrochloride were instilled into the nostrils. The dyspnea was relieved almost immediately and the patient fell asleep in her chair. The doctor left. The patient requested that she be allowed to go to bed. At about 9 o'clock another teaspoonful of cheracol was given. At about 9:40 the doctor was hastily called again because of a recurrence of the former symptoms. On arriving, he found the patient in a semiconscious state with all the former symptoms and signs. An examination of the pulse showed a rate of 130. The pulse was strong and regular and continued to be so until about three minutes before her death, which occurred at 10:03. The sudden onset and cessation of symptoms in this case cause me to wonder about the possibilities of an idiosyncrasy to a drug in an asthmatic patient. Please omit name.

M.D., Wyoming.

ANSWER.—Cheracol is composed of the following ingredients to the ounce:

Potassium guaiacol sulfate.....	0.5 Gm.
Ammonium chloride.....	0.5 Gm.
Codeine phosphate.....	0.065 Gm.
Antimony and potassium tartrate.....	0.005 Gm.
Chloroform.....	0.12 cc.
Syrup of white pine and wild cherry.....	30 cc.

Codeine (0.008 Gm. to the teaspoonful) is the only likely drug in this formula that might produce an attack of asthma in a hypersensitive person. There are, however, strong objections to the likelihood of this in the history quoted. The age of the patient, 74, with a duration of asthma of only several years, is against the probability of the attacks being due to extrinsic causes. Moreover, it is improbable that a person of 74 should develop a new sensitivity to codeine. If such sensitivity had previously been present to such a common drug, the patient and the family would probably have been aware of it. The rapid relief obtained from the first attack of asthma described here by such simple measures as steam inhalation with compound tincture of benzoin and instillation of dl-1-phenyl-2-aminopropanol-1-hydrochloride into the nostrils is not characteristic of asthma due to a drug reaction. The reaction due to drugs is usually severe, prolonged and very difficult to control. The presence of fever is, moreover, much more characteristic of an infectious origin rather than a drug reaction, although a febrile reaction may occur as an unusual symptom of drug idiosyncrasy.

INTRAVENOUS EVIPAL FOR DENTAL SURGERY

To the Editor:—At times I am called in to give a general anesthetic for a dentist when he has a patient who so desires something rather than a local anesthetic. Would intravenous evipal bring about a complete enough anesthesia and muscular relaxation for a fifteen minute work period in the mouth? Would it be perfectly safe, and what are the contraindications if any? Please omit name.

M.D., North Dakota.

ANSWER.—The intravenous method of administering general anesthetics, although not exactly new, is not recommended for those who are inexperienced in the use of intravenous anesthetics. The method is not widely used and it has not been standardized. Sodium *n*-methyl-cyclohexenyl methyl malonyl urea (evipal) has not been accepted by the Council on Pharmacy and Chemistry. Some patients are fairly resistant to evipal and the amount of the drug necessary to produce anesthesia depends on whether or not the patient has had preliminary medication, which usually is not administered to dental patients. The use of the anesthetic agent is safer when the patient is lying on an operating table than when he is in a sitting position in a chair. The drug does not affect the pharyngeal reflex particularly, and when the patient is in the sitting position any blood or secretions in the mouth would tend to gravitate to the throat and produce coughing. One also would be faced with the possible danger of aspiration. It would be impossible to predict that the use of this drug in the instances mentioned could be said to be perfectly safe. Since the drug depresses respiration during and after the induction of surgical anesthesia, one

must avoid its use in cases in which pulmonary disease is associated with dyspnea and also in cases in which any respiratory obstruction exists or may occur during the operation or immediately afterward. Its administration to young children should be avoided because of marked depression of respiration and the very small respiratory passage through which the child must breathe.

If one wishes to use this drug in the cases mentioned, it would be well for one first to become experienced in its use in other types of cases and become familiar with actions of the drug. The intermittent method of injection should be employed. A quantity sufficient to produce anesthesia for the entire operation should not be injected at one time. There are many articles (from 350 to 400) on the subject available here and abroad. A few of these articles, which are rather easily available, are listed as references. If a medical library is not readily available, articles might be borrowed, or anesthetists of one's acquaintance would be glad to send reprints on the subject.

TOXIC EFFECT OF CYANIDE USED IN CASE-HARDENING COMPOUND

To the Editor:—A man was brought to me who had inhaled concentrated fumes from "Kasenit," a case hardening chemical made by the Kasenit Company of New York. His condition was one of shock with pallid facies, rapid irregular pulse, and blood pressure 110 systolic, 60 diastolic. A severe bronchial irritation of the right lung especially was noted and coughing was continuous. The reflexes were negative. After two days rest the severe cough had subsided, but some moisture was noted in the right side of the chest; at no time was there any rise of temperature. The blood pressure rose to 190 systolic, 110 diastolic. The heart beat was irregular but no pulse deficit was present. The cardiac irregularity was improved to what it was when he was first seen. At this time he developed a weakness in the feet with severe pain in the legs and feet. The feet began to swell. After a few days the swelling decreased and the pain was very much less. He is now in the hospital and it has been ten days since he inhaled the fumes from the "Kasenit." The question has arisen as to whether or not the inhalation of the kasenit fumes caused or precipitated his condition or whether he simply had a heart attack.

J. A. MEASE JR., M.D., Dunedin, Fla.

ANSWER.—The firm mentioned is believed to manufacture a series of case-hardening compounds, chiefly of the open fire type, all of which are marketed under the general trade mark of "Kasenit." This being true, the reference to "Kasenit" in the query fails to identify any particular case-hardening substance. From the acuteness and the severity of the manifestations described, the tendency is to suspect that the case-hardening material in use was one of the cyanides, probably sodium cyanide. Cyanides constitute the chief case-hardening substance in many types of industry. The carelessness with which it is frequently used invites concern. However, the extent of practical hazard is distinctly lessened by the fact that, under the action of heat, cyanides are rather quickly changed into carbonates; thus much of the dust and fumes observable around case-hardening operations represents relatively harmless substances.

In this instance the manifestations described do not include any single characteristic feature of acute cyanide poisoning. In nonfatal cyanide poisoning the victim quickly develops convulsions, followed by a stage of multiple paralyses. During this period the respirations are slow and shallow. After the return of consciousness, prolonged vomiting frequently takes place. For a period of days or weeks there may be observed great weakness, unstable gait, speech difficulties and drowsiness, together with pains in various portions of the body, including headache. Whenever a person has ingested cyanogen compounds or inhaled concentrated vapors or gases to the point that convulsions take place, always there is a marked odor of hydrocyanic acid on the breath. Almost invariably this fact may serve in the making of a precise diagnosis.

In the absence of exact information as to the chemical nature of the case-hardening compound in use, and in the absence of clinical manifestations characteristic of the usual substances used in case-hardening, it becomes necessary to maintain for the time being that the episode described is probably the result of some cardiovascular accident not directly precipitated by any characteristic feature of employment. It is recognized that

excessive heat, arduous labor and other circumstances connected with the work may have played some part in the precipitation of this attack. Even so, this must be recognized as not characteristic of this one particular occupation but as common to a great many.

DIAGNOSIS OF PRECORDIAL PAIN

To the Editor:—My mother, aged 65, has been complaining for the past year of "uneasiness around the epigastric region," "headache." Four months ago she started to complain of pain around both shoulders, radiating to the epigastric region and to the precordium; the duration was from half an hour to three quarters of an hour. Gradually the frequency and severity of the pain has increased and now she gets those attacks almost every day. The pain is not relieved by nitrites, as I have tried them on her. The attacks have no relation to effort, as she has been in bed for the past two months. The only thing that relieves her pain is one-half grain (0.03 Gm.) of codeine. Now she is out of bed but the fear of a coming attack makes her go to bed and stay there all day. She has a blood pressure of 164/110, the systolic fluctuating from 180 to 160 on different occasions, while the diastolic has been from 110 to 104. She complains of belching also and difficulty in swallowing. Urinalysis, blood chemistry and the blood count have been within normal range. The electrocardiographic record revealed myocardial damage in the slurring of QRS and in the abnormal ST intervals. Coronary involvement was suggested by the large Q. The PR interval was 0.16 second, the QRS complex 0.08 second and there was left axis deviation. In a roentgenogram of the chest the heart shadow appeared enlarged in the region of the left ventricle. The aorta appeared somewhat tortuous and increased in width and suggestive of atheromatous changes. A gastrointestinal series gave negative results. She has had a preparation of theobromine and phenobarbital 5 grains (0.3 Gm.) twice a day and carminatives. During the attack (I happened to witness two) there is no change in the blood pressure; she does not go into shock but sweats very slightly. How would you explain her difficulty on swallowing when there is no abnormality in the esophagus and what would you suggest in the line of therapy? Is the precordial pain due to cardiac fatigue (cardiac ischemia)? Please omit name and address if answered through *THE JOURNAL*.

M.D., California.

ANSWER.—A definite answer cannot be given. It is possible that the pain described is anginal in origin, even though it is not directly consequent on effort. Dysphagia is occasionally complained of in the presence of some abnormal cardiac condition causing pressure on the esophagus and occasionally in those suffering from anginal attacks, even when no pathologic condition can be demonstrated. In the latter case it is not so much a dysphagia as that the act of swallowing may bring on the anginal pain. The history given in this case, however, is not a convincing story of anginal attacks. The electrocardiographic observations are no more than might be concomitant with a heart normal for the age.

A hypertrophic osteo-arthritis must be considered, or some other anatomic change in the spine. The pain may be similar to that described here, and in the case of cervical arthritis the patient may designate pain radiating upward over the occiput as "headache." A spinal tumor must always be considered, even though improbable.

Disease of the gallbladder must be considered, even though the possibility appears somewhat remote.

If the pain is anginal in origin, one of the purine base diuretics may be used, and its use persisted in for a period of a few weeks, even if there is no improvement at first.

SIGNIFICANCE OF DICK TEST

To the Editor:—Will you please advise me as to the significance of the Dick test in an adult who required 90 skin test doses before a positive reaction was obtained. If this indicates an increased antitoxin content of the blood, what is the best and easiest method to titrate the antitoxin titer of the blood. In what conditions is this resistance to the Dick test seen? Kindly omit name.

M.D., New York.

ANSWER.—If the skin test solution is potent, which is probably the case if it is a commercial preparation, a patient who gives negative reactions to less than 90 skin test doses of toxin has a comparatively high degree of immunity to scarlet fever. Such higher degrees of immunity are commonly found in persons who have had an attack of scarlet fever complicated by otitis media and mastoiditis accompanied by a purulent discharge over a long period or other suppurative sequelae of scarlet fever. The correspondent already has titrated the antitoxin in the patient's blood. The skin test is a quantitative as well as a qualitative chemical test for scarlet fever antitoxin in the blood. To titrate the antitoxin by neutralization tests in vitro, collect blood from the patient by aseptic technique, allow it to clot in the icebox, collect the serum free from red cells, add 0.5 per cent phenol and make cultures appropriate for determining sterility. Make various dilutions in sterile physiologic solution of sodium chloride of the sterile serum and mix

each dilution with an equal volume of sterile scarlet fever toxin which contains 10 skin test doses in each 0.1 cc. Make control solutions by mixing the various serum dilutions with equal volumes of sterile physiologic solution of sodium chloride and by mixing the toxin solution with an equal volume of sterile physiologic solution of sodium chloride.

After allowing the various mixtures to stand about one and one-half hours at room temperature, make skin tests on human beings known to be susceptible to scarlet fever, making in each individual three intradermal tests consisting of:

First, 0.1 cc. of the toxin control solution, which is the toxin diluted with an equal volume of physiologic solution of sodium chloride.

Second, 0.1 cc. of the toxin-antitoxin mixture, which is the toxin mixed with an equal volume of one of the dilutions of the serum to be tested.

Third, 0.1 cc. of the serum control, which is the dilution of the serum used in the second test mixed with an equal volume of physiologic solution of sodium chloride instead of scarlet fever toxin.

The reactions should be observed at the end of twenty-four hours. The reaction in the first test should be positive and in the third test negative. In the second test the reaction will be negative if the serum in the dilution tested contains sufficient antitoxin to neutralize 5 skin test doses of toxin. Most convalescent serums do not neutralize completely in dilutions of more than 1 in 10.

PARAMETRITIS OF BROAD LIGAMENT

To the Editor.—Since early in April 1936 a married woman, aged 27, has complained of pain in the lower part of the abdomen, most marked on the right side. The pain radiates into the back, especially the right sacro-iliac region. There are no associated gastro-intestinal symptoms. In January the patient contracted gonorrhea from her husband. Smears taken during March and April were negative for gram-negative intracellular diplococci. Physical examination by me and by a consultant revealed nothing of significance except in the pelvis, where moderate thickening and acute tenderness in the broad ligaments were noted. In view of this situation and a history of bilateral salpingo-oophorectomy done five years ago for "pus tubes" elsewhere, bed rest, sedation and long, hot potassium permanganate douches were advised. There was no improvement after four weeks. The Kahn test is negative. The urine (catheterized and voided) is normal except for diplococci in the stained sediment. Retrograde pyelograms were negative. Cystoscopy revealed no abnormality other than a lumbar lordosis, which has increased gradually. During hospitalization, Elliott treatments were given and fluids forced to 4,000 cc. daily. No improvement has occurred. Is foreign protein therapy likely to offer anything in this instance? If so, what type would you advise? What other therapeutic measures, if any, might influence this inflammatory condition? Please omit name.

M.D., Michigan.

ANSWER.—The history suggests a chronic parametritis of the broad ligament, probably secondary to a chronic endocervicitis. There may be a thickening of the sacral-uterine ligaments. The focus of infection in the cervix should be eradicated in this patient by the Sturmdorf operation in preference to electrical coagulation. It is doubtful whether foreign protein therapy would be of any value here until surgical measures have been used. Such therapy might be helpful later, and sterile skim milk is satisfactory with an initial dose of 1 cc. intramuscularly, repeated twice weekly with gradually increasing amounts.

TREATMENT OF ACUTE CERVICAL ADENITIS

To the Editor.—What is the rational treatment of acute cervical adenitis today? Before suppuration, is heat or cold indicated for local application? Are the x-rays of proved value? Is the use of foreign protein or vaccine advised? In my experience these cases have been resistant to any form of treatment. The organisms found when suppuration occurs is usually a streptococcus. All these cases seem to follow a recent nasopharyngitis and are distinguished from infectious mononucleosis by the blood picture and the process being limited to the cervical glands. What treatment should be employed for cervical adenitis accompanying scarlet fever? Please omit name.

M.D., California.

ANSWER.—Almost any of the pyogenic bacteria involving the lymph drainage area may cause acute cervical adenitis, but there is no characteristic change due to any one organism. It may result from an acute process, usually in the nose, mouth or throat but occasionally in the sinuses or skin, with sudden onset and rapid swelling. Usually the swelling of the glands subsides in a few days or weeks. Only a few suppurate, most of them requiring to be drained after one or two weeks. Some gland abscesses lie deep in the neck, making the diagnosis of suppuration difficult. Cervical adenitis associated with scarlet fever, diphtheria and other epidemic diseases as influenza come under this group. Occasionally the source is only a nasopharyngitis with little local reaction.

Before suppuration, the usual treatment is dry heat. Occasionally moist heat is more soothing but it is more difficult to apply satisfactorily. The cervical adenitis may persist for some time without suppuration as a hard indurated process. Usually this gradually disappears without treatment. A similar hard brawny induration without suppuration occurs in association with a chronic infection in the drainage area such as root abscesses or sinus infection. The glands may either swell up suddenly as in the acute infectious diseases or develop gradually. Any pyogenic organisms may cause it, although the streptococcus has been found more frequently. One should be certain that suppuration deep in the neck is not overlooked and then attempt to clear up any foci of infection. The general immunity, which may be low, should be built up by any necessary medical treatment. If the etiologic organism can be determined, a vaccine may be helpful and no doubt a foreign protein may be of value occasionally; but caution in its use is advisable. Locally either moist or dry heat may be helpful.

X-ray treatments by a roentgenologist with very small exposures of approximately one-fourth erythema dose, smaller than in furunculosis or tuberculosis, have been found to stimulate the process and either aid absorption or hasten suppuration.

TREATMENT OF EXTRASYSTOLE OF HEART

To the Editor.—A man, aged 60, apparently in perfect health, with physical signs negative, complains only of one disturbance—extrasystole, or "the heart skipping a beat." I can find no pathologic or functional cause. Yet I fear he is developing into a cardiac cripple of neurotic type. Can you suggest anything better than psychology or advising a prolonged vacation? Please omit name.

M.D., Indiana.

ANSWER.—These are exceedingly difficult cases. The clinical importance of an occasional extrasystole is slight and one hesitates to advise medication, so by all means continue along the line suggested in the question.

Of all the drugs used to combat this situation, the salts of quinidine and quinine seem to have the most effect. A combination of quinidine sulfate and strychnine sulfate is credited with good effect, although it is difficult to see why this should abolish the extrasystole. One must admit that this is bad therapeutics and carefully weigh the disadvantages of the use of cardiac accelerators. Occasionally it is found that coronary dilators will abolish this arrhythmia, even in those cases in which cardiac abnormality cannot be demonstrated. The use of theobromine or theophylline compounds is, at least, without danger.

Lastly, a general sedative will sometimes accomplish the result. Bromides or barbituric acid compounds may be used for this purpose, but again this is bad therapeutics and should not be lightly undertaken.

MORPHINE FOR PAIN IN MALIGNANT HYPERTENSION

To the Editor.—I have a sister, aged 35, with malignant hypertension. She has had this for five years. Her extremities, hands, arms and legs from the knees down show a loss of muscular tissue and the skin appears to be tightened about the bones. She has had circulatory disturbances through her legs during the past year and the skin appears gangrene of two toes. About four months ago she had a cerebral hemorrhage leaving her paralyzed in her right arm and partially her right leg. The gangrene developed at that time. About a month ago she bumped her knee on a cradle and a large apparently trophic ulcer has developed on the knee where there was very little tissue between the skin and the bone, and it is for this reason I am writing to find out what the best management would be for alleviating pain and healing this ulcer, which is about the size of a quarter (24 mm.) and does not appear deep but continues to spread, becoming black and dry in the center, with a whitish gray border. Hot dressings cause rapid spread of the lesion. The blood pressure varies between 230/130 and 215/120. She has mild diabetes for which she is receiving insulin twice daily. Realizing what the ultimate outcome will be, I have sought in vain for some method other than morphine for the alleviation of pain. Any suggestion you may offer will be greatly appreciated. Please omit name.

M.D., Wisconsin.

ANSWER.—From the facts as given, the ultimate prognosis is dark. In view of the diabetes and the tendency for these necrotic lesions to spread, one feels that termination of this tragedy is not far off. Under these circumstances it appears that the judicious administration of morphine is fully justified. Morphine is still the most effective medication for the relief of pain. In the patient's extremely weakened state and with cerebral circulation impaired, small doses, starting with 0.008 Gm. (one-eighth grain), will probably suffice to bring comfort. Certain other methods of relieving pain, such as section of nerve roots or injection of alcohol into the nerve trunks, are obviously out of the question because of the risk of further gangrene. Aminopyrine and related compounds are probably more toxic than morphine.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 22-24. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, Sept. 13. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Basic Science*. Tucson, June 15. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical*. Phoenix, July 6-7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: Little Rock, June 17-18. Sec., State Medical Board of the Arkansas Medical Society, Dr. A. S. Buchanan, Prescott.

CALIFORNIA: San Francisco, June 28-July 1, and Los Angeles, July 19-22. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, July 6. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Medical (Homeopathic)*. Derby, July 12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven. *Medical (Regular)*. Hartford, July 13-14. *Endorsement*. Hartford, July 27. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, June 28-29. *Medical*. Washington, July 12-13. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

HAWAII: Honolulu, July 12-15. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

IDAHO: Boise, Oct. 5. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

ILLINOIS: Chicago, June 22-25 and Oct. 19-21. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration, Dr. William R. Davidson, 301 State House.

IOWA: *Basic Science*. Des Moines, July 13. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

KANSAS: Topeka, June 15-16. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

MAINE: Augusta, July 6-7. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore.

MASSACHUSETTS: Boston, July 13-15. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MINNESOTA: Minneapolis, June 15-17. Sec., Dr. Julian F. DuBois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June 23-24. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Oct. 5-6. Sec., Dr. S. A. Cooney, 205 Power Block, Helena.

NEVADA: *Reciprocity*. Carson City, August 2. Sec., Dr. John E. Worden, Carson City.

NEW HAMPSHIRE: Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 11-12. Sec., Dr. Le Grand Ward, Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OREGON: *Medical*. Portland, June 15-17. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science*. Corvallis, July 17. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 7. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, July 1-2. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 20-21. Director of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

TENNESSEE: Knoxville, Memphis and Nashville, June 17-18. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: Austin, June 21-23. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

UTAH: Salt Lake City, June 21-23. Dir., Department of Registration, Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, June 16-18. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WASHINGTON: *Basic Science*. Seattle, July 8-9. *Medical*. Seattle, July 12-14. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WEST VIRGINIA: Fairmont, July 12. Sec., Public Health Council, Dr. Arthur E. McClure, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 29-July 2. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the *National Board of Medical Examiners and Special Boards* were published in THE JOURNAL, June 5, page 1934.

Illinois January Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education, reports the written and practical examination held in Chicago, Jan. 26-28, 1937. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Sixty-three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Chicago Medical School.....	(1936)	81,	
82, 82, 83, (1937) 80, 81, 81,* 84, 86, 88

Book Notices

Administrative Psychiatry. By William A. Bryan, M.D., Superintendent, Worcester State Hospital, Worcester, Mass. Cloth. Price, \$3.50. Pp. 349. New York: W. W. Norton & Company, Inc., 1936.

The title of this book suggests that it is meant for the state hospital administrator and for him it could well become a "how book," dictionary and Bible. But to assume that its usability and applicability is limited to psychiatrists in the administrative department of hospitals would be to overlook the most helpful presentation of hospital therapy and therapeutic management yet written. Every psychiatrist will find the book worth perusing, whether he is connected with an institution or not, but particularly for the institutional psychiatrist it can be an extremely valuable aid and guide. It contains many practical suggestions for all members of the hospital personnel—the business manager, the nursing staff, the therapists, the research members. Remarkable in the book is the point of view. The author is courageous and systematic. He is also progressive, as indicated in such opinions as that the autocratic executive in the hospital organization must give way to a creative leader, with the goal psychiatric rather than economic; the solution to the psychiatric nursing problem is the use of psychiatrically trained graduate nurses working an eight hour duty day; the staff and employees of the state institution should not be isolated from community life by being required to live on the hospital grounds; all group activity is a psychotherapy and should be so planned; occupational and industrial therapy is not therapy if it merely teaches a craft or is an economy for the hospital, and every psychiatric hospital should be a teaching center and carry on research work. Dr. Bryan is courageous because he recognizes that some state hospital psychiatrists will regard many of his suggestions with skepticism and think that they are either impracticable or impossible because of their idealism. But the author bluntly charges these hospital leaders with the responsibility for community leadership, legislative changes and psychiatric advance. The author is systematic. He approaches his subject from many angles. He gives many details and specific helping charts for employees, division of responsibility for occupation, teaching outlines, letters to patients and relatives, clinic organization, responsibilities of social workers, and research protocols.

The chief criticism of the book is that it implies that psychiatry exists only in state hospitals. The author states that "psychiatry has become the function of the state." The scotoma for the private practitioner of psychiatry and the private psychiatric hospital is a serious flaw. Furthermore, one would infer from his book that psychiatry is applied only to the psychoses. Although he lauds the mental hygiene movement, is unusually progressive in his ideas regarding social workers, and mentions the importance of fostering contacts with ministers, lawyers and educators, he apparently does not consider these fields as being a part of an extramural psychiatry. Psychiatry is considered only in terms of mass care of the psychoses and the management of the individual with these illnesses. Other criticisms, briefly stated, are that the book is too short to give help in the management of the individual patient; that, while the author semipologetically acknowledges his acceptance of the Freudian concepts as being most helpful, no apparent application of them to treatment is suggested, and that most of the source references are used superficially and the consequent bibliography is of little use to the student who wants to go further than the author's own experience or ideas.

Death-Fighters. By Paul de Kruif and A. M. Smith. Paper. Pp. 39. Detroit, Michigan: Detroit News, 1936.

This pamphlet is a shocker. It bristles with such terms as "murder," "infamy," "slaughter," "mass murder," "imbecility" and "idiocy." It fastens on the father of a tuberculous family such terms as "mulishness" and accuses him of "if not killing his children with a shotgun, at least coughing them to death with TB microbes." The attitude of citizens at large toward tuberculosis is characterized as murderous complacency. The whole technic is that of shrieking murder for the purpose of attracting public attention. The reader might assume that the

Detroit health department and the medical profession in Detroit had never before paid any attention to the tuberculosis problem and that no attention had been paid to it elsewhere. The thirty years' fight that has been carried on throughout the country is ignored or minimized as if it had done nothing. Acknowledging the many excellent features of the Detroit plan for fighting tuberculosis, out of which this pamphlet grows, one cannot escape the conviction that the pamphlet is its least desirable feature. Calm consideration should convince any experienced worker in public health that shrieking murder may be an excellent way to attract attention and achieve a brief flare of publicity, but it is not the way to make sustained progress. Moreover, it is unfair to the equally earnest but less spectacular toilers in other fields to intimate that in Detroit and in Detroit alone a public conscience has been shown that will result in the eradication of tuberculosis. Finally, the pamphlet leaves the implication that tuberculosis can be overcome quickly. This is not true. The fight must be a long one. Neither individual nor community can be kept forever at a high pitch of enthusiasm. The greater the action, the greater the reaction.

Técnicas de laboratorio clínico. Por Fernando de la Fuente Hita, Jefe de laboratorio del dispensario antituberculoso de Buenavista y del hospital de asistencia social. Paper. Price, 5 pesetas. Pp. 123, with illustrations. Madrid: Gráficas Sánchez, 1936.

This book reviews laboratory tests. The technics discussed by the author are given in the form of articles, most of which were published by the author as original articles in Spanish medical journals from 1928 to 1933. The book includes the following articles: 1. A modification of Volhard's method for quantitative determination of chlorides in urine. The modification consists in replacing nitric acid with an acetic acid solution (for destruction of organic matter in the urine) and in titrating the excess of silver nitrate (after precipitation of the chlorides has taken place) with a known solution of sodium chloride in the presence of yellow potassium chromate as indicator. 2. The technic of the Vernes perethynol test for the diagnosis of syphilis, as it is performed at the Institut prophylactique de Paris. Also a study of the sensitivity of the test and, in this connection, indications of advisability of verifying the results of the test by rereading the results twenty-four hours after the test has been made. 3. Micromethod for quantitative determination of dextrose in the blood. The method is based on Myers and Baley's macromethod, which in turn is a modification of the Lewis-Benedict method for dextrose. 4. Technic, diagnostic and prognostic value of the Vernes resorcinol test for tuberculosis. 5. Technic for deviation of the complement by using the patient's active blood serum. 6. Technic for determination of hemolysins in cerebrospinal fluid in investigating meningeal permeability. 7. Technic and results of the Vernes photometric interpretation of the third Kahn sero-albumin test for the diagnosis of cancer. 8. Technic for evaluation of pyuria and prognostic value of the test in infections of the urinary tract. 9. New quotient for velocity of sedimentation test (Fahræus's reaction). 10. Weltmann's simplified serocoagulation test. 11. Description of Kovarski's modified micro-ureometer and technic. 12. Review of Borowskaja's method for preparation of colloidal gold solutions and Fuente-Hita's technic for the same purpose. Many of the articles published are six and eight years old.

The Extra Pharmacopœia (Martindale). Volume I. Published by direction of the Council of the Pharmaceutical Society of Great Britain. In two volumes. Twenty-first edition. Cloth. Price, 27s. 6d. Pp. 1,182. London: Pharmaceutical Press, 1936.

The first edition of Martindale's Extra Pharmacopœia appeared in 1883 and since 1912 it has appeared in two volumes. Volume I is devoted mainly to treatment with drugs and chemicals. Volume II, which has always been less popular, is concerned with matters of diagnosis, analysis, assay and "divers subjects—which could not be included in the first volume." It is an extensive compendium of therapeutic agents employed in England and the British Empire. There is no exact counterpart published in this country. It deals primarily with the preparations found in the British Pharmacopœia and the British Pharmaceutical Codex but differs essentially from the latter in not being an official publication in any sense of the word.

Therapeutic description of each item consists in most cases of a preliminary paragraph followed by brief excerpts from the current literature. Preparations are designated as being included in various English formularies or in the official pharmacopeias of other nations. It is noted, therefore, that no preparation is indicated as being an N. F. or N. N. R. item. Frequent reference is made to articles that have appeared in *THE JOURNAL* and direct quotations from reports of the official councils of the American Medical Association are made in connection with cevitamic acid (*Acidum Ascorbicum* B. P. Add.); the claims for vitamins A, B₁ and D; the standardization of liver preparations; the Council's selection of the word "ergonovine" for use in N. N. R.; the reports of the Advisory Committee on Nomenclature of Endocrine Principles and the series of articles that comprise Glandular Physiology and Therapy. On the other hand, the volume can hardly be considered (or expected to be) an adequate guide for the critical evaluation of the almost endless number of therapeutic preparations that are listed. This edition is thoroughly abreast of the times and includes preparations that have recently been added to the British and U. S. pharmacopeias as well as the newer remedies reported in the medical literature. The volume represents an enormous amount of work, and the extensive listing of the names of the drugs alone is of value. The book has a comprehensive index containing approximately 11,000 entries and follows the general style of previous editions. It should be welcomed by those who have found the preceding volumes useful.

History of Chinese Medicine: Being a Chronicle of Medical Happenings in China from Ancient Times to the Present Period. By K. Chinlin Wong, Licentiate of Medicine and Surgery, Hongkong, and Wu Lien-teh, M.A., M.D., Dr.M.Sc., Director, National Quarantine Service. Second edition. Cloth. Pp. 906, with 38 illustrations. Shanghai, China: National Quarantine Service, 1936.

A review of the first edition was published in *THE JOURNAL*, July 1, 1933. That a second edition was forthcoming about four years later attests the fact that the history of Chinese medicine is a fascinating story. The volume comprises two distinct books: Book one, by Dr. K. C. Wong, lecturer on medical history at the National University in Shanghai, deals with the history of the indigenous art from the earliest recorded period to the close of the eighteenth century; and book two, by Dr. Wu Lien-teh, director of the Manchurian Plague Prevention Service, treats of the last 130 years, the period since the introduction into China of Western medicine by the foreign missionaries. Book one is the smaller for two reasons: (1) there are many difficulties inherent in the collection of records of medical discoveries during the very early centuries covered by the first book and (2) medical progress in China came to a standstill long before the close of the seventeenth century and remained so throughout the fruitful years following Harvey's discovery of the circulation of the blood; it was resuscitated only when the medical missions came to China. In the second edition, some new chapters have been added and several others have been rewritten. Book one now contains twenty-six chapters instead of twenty-one. The chapters on ancient drugs, decline of the native practice, and prominent practitioners of the Ching dynasty, are among the new chapters. In book two, a chapter on the consolidation of medical work under government auspices in the last eight years has been added. The crowning feat of public health work in China during this period (1928-1936) was the establishment of a ministry of health under the national government in Nanking. The ministry of health has advanced rapidly toward a modern public health program, establishing school health service, which was extended to fifty municipal schools; child and maternity health measures, including the training of native midwives; health education through posters, pamphlets and a monthly magazine; public health nursing, and an industrial health program. In 1930 a Peiping committee on maternal health was established and the first birth control clinic was opened under the auspices of this committee in the same year. On account of the need of modern doctors, a program was also laid out for the establishment of medical schools in each of the provinces, the standards of which were to be the consideration of a committee established jointly by the ministers of education and health. Among other councils under the ministry of health were the Council on Research, the council on publication, the council on medical missions, and steps were

being taken for the formation of a council on pharmacy and chemistry. The Chinese Pharmacopeia, based largely on the Pharmacopeia of the United States, Japan, Great Britain and Germany, was adopted in 1930.

The Social Component in Medical Care: A Study of One Hundred Cases from the Presbyterian Hospital in the City of New York. By Janet Thornton, Director, Social Service Department. In collaboration with Marjorie Strauss Knauth, Assistant Physician, Department of Medicine. Cloth. Price, \$3. Pp. 411. New York: Columbia University Press, 1937.

One hundred patients of the Presbyterian Hospital in New York were studied in detail by physicians and social workers. The purpose was "to discover and describe the social disorders of a certain number of patients and to determine whether the patients' reactions to such disorders were unfavorable to health." The cases are divided into acute, recurrent and chronic. The adverse social factors associated with individual problems of ill health include subsistence, economic protection and faulty personal habits. Measures were undertaken to remedy these unfavorable social factors through control of the environment, supplying deficiencies in environment, helping the patient to utilize available resources, removing obstacles to care, and moving the patient to a more favorable environment. To influence conduct, dependence was placed on explanations, elucidations and demonstrations. An effort was also made to foster more healthful habits. Such treatment required extensive personal attention to each patient. Because only a small percentage of the patients were indigents or in the extremely low income classes, some of the most common economic factors had little importance. Financial factors were not found to interfere with the securing of medical care. There were few cases in which shelter or food were deficient. Labor, although sometimes apparently excessive, was found in several cases to be a help rather than a hindrance to recovery. One clearly essential factor of such work is a close, sympathetic relation with and long time, personal effort by a physician in cooperation with medical social service workers. Such treatment would manifestly be impossible under any system of sickness insurance in which close personal relations were not assured.

Les lésions organiques du cœur: Étude clinique, anatomique et thérapeutique. Par R. Lutembacher. Cloth. Price, 300 francs. Pp. 351, with 185 illustrations. Paris: Masson & Cie, 1936.

The purpose of the author is clearly stated in the introduction. He recognizes the rather schematic conception of disease that results from didactic teaching with the embarrassing confusion that follows when the student and practitioner are confronted with the concrete facts of daily practice. "Clinical teaching controlled by necropsy is the indispensable complement of theoretical instruction." This work, the result of twenty years of practical experience with the diseases of the heart, is issued as a contribution to such clinical teaching. The book is really an atlas of 185 illustrations from photographs of hearts found at necropsy. The publishers are justified in praising these not only as faithful reproductions of the anatomic specimens but also as examples of photography that is highly artistic. With the aid of small guide-diagrams and the legends one is easily able to identify the various parts of the organ. Brief clinical histories and abstracts of the other conditions found at the necropsy are furnished. Around these illustrations has been built a descriptive outline of certain types of heart disease, such as the inflammations, valvular lesions, disorders of the coronary artery, and aneurysm, with some consideration of diagnosis and treatment. The latter feature is occasionally rather overemphasized, with intravenous medication too frequently advocated. This skeleton text may help make the book of worth to the practitioner but the real value, as has been said, lies in the illustrations. The author, already well known in cardiology as an appended list of some hundred of his articles attests, has really added to his reputation by this fine volume, which is the result of patient collecting of these histories and anatomic specimens that has enabled him to present in an attractive and instructive form this unusual book. The publisher's work has been excellently done. The remarkably clear illustrations are of natural size. Type, paper, margins are all that could be desired. The pages measure 25 by 32 centimeters.

Oral Diagnosis and Treatment Planning: A Textbook for Students and Practitioners of Dentistry and Medicine. Edited by Samuel Charles Miller, D.D.S., Associate Professor in Charge of Periodontia Department, New York University College of Dentistry. With an introduction by Allen T. Newman, M.S., D.D.S., Dean, New York University College of Dentistry. Cloth. Price, \$7.50. Pp. 620, with 562 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

This is intended primarily as a text and reference book for dental students, though it is of equal interest and value to practitioners of both dentistry and medicine. It represents the trend in dental literature and education to extend the attention from the teeth and their immediate supporting tissues to the oral cavity and all the conditions manifested in the mouth and associated parts. It especially emphasizes the relation between oral and systemic conditions and tends to break down the lines of demarcation between dentistry and medicine. The chapters treat such subjects as oral diagnosis, head pain and pain of dental origin, mouth conditions in children, radiographic diagnosis, abnormalities of the temporomandibular articulation, tumors of the oral mucous membrane, mouth infections and their relation to systemic disease, and oral manifestations of endocrine dysfunctions. There is an interesting chapter on oral and dental diseases of occupational origin. While this is necessarily sketchy, it is interesting and valuable for reference. Such books are extremely valuable but tend of course to be somewhat superficial. They cannot be a substitute for a thorough knowledge of pathology. The chief criticism that might be made of the book is that it is a mixture of pathology, clinical diagnosis and dental technical procedure; but, in a field so comparatively new, satisfactory form and organization can be arrived at only by experience and experimentation. The book is profusely illustrated both in black and white and in color, and most of the illustrations are well reproduced. Naturally there are statements that might be questioned. Many practitioners may find it a valuable book of reference.

Control of Animal Parasites: General Principles and Their Application. By Maurice C. Hall, Ph.D., D.Sc., D.V.M. Cloth. Price, \$2. Pp. 162, with illustrations. Evanston, Illinois: North American Veterinarian, 1936.

This is a book of biologic strategy, a phase of scientific activity all too little developed in both instruction and practice in applied biology and medicine. The author treats, as a problem of attack along the lines of well established military principles, the control of parasites in domesticated animals and in man in instances, such as trichinosis, in which man is or may be involved as one of the facultative or obligatory hosts. Diagrams present in visual form all the factors involved in the problems of control. Life histories are lines of communication between infested and susceptible host animals. The weapons available for direct attack on the parasite, on its lines of communication and on its reservoir hosts are brought out of the arsenal. Such a presentation is especially valuable to the physician and the veterinarian in showing the part each of these plays in the campaign for the relief of his patients and the protection of his clientele from infection. It also affords a point of view not elsewhere adequately and so dramatically presented of great value in instruction in parasitology and in public health. Specific examples in the medical fields are the plans of campaign against yellow fever, malaria, trichinosis, beef and pork tapeworms, dog fleas, pinworms, hookworms, and hydatid disease.

Pathologie der Functionen und Regulationen. Von Prof. Dr. L. Lichtwitz, Chef der medizinischen Abteilung des Montefiore Hospital, New York City. Paper. Price, 13.25 florins. Pp. 332, with 125 illustrations. Leiden: A. W. Sijthoff's Uitgeversmaatschappij N. V., 1936.

This embraces not only recent advances in medicine but a point of view developed by the author which is provocative and enlightening. His main thesis is that there exists a neurohormonal regulatory mechanism in the diencephalic hypophyseal region which governs function generally. A pointed example is the thyroid gland. Normally the vegetative center in the diencephalon activates the formation of thyrotropic hormone in the hypophysis, which in turn stimulates the thyroid gland to the formation of thyroxine. The latter acts on the diencephalic center in a negative way, preventing overstimulation of the hypophysis until an equilibrium is established. Thus the pathogenesis of disease as well as the other diseases

discussed must be considered in a new light, as should the methods of treatment. Similarly the author takes up the various diseases as affecting systems rather than a single organ. In addition to his discussion of the glands of internal secretion and the pathology of their functions, the author stresses the important rôle of the diencephalic hypophyseal complex in the pathogenesis of immunity, rheumatic fever, arthritis, gout, blood dyscrasias, hypertension, nephritis and nephrosis. Although much of the material presented is gathered from the literature, a large percentage is from the author's personal clinical, chemical and pathologic experience. There are numerous case histories, reproductions of photographs of patients, and roentgenograms, as well as graphs representing various tolerance tests and chemical analyses. Unfortunately, many of the inferences were drawn from the finding of a central lesion in association with a peripheral one, implying that the former pathologic condition predisposed to the latter. Similarly the central action of drugs was considered as proof presupposing that the drug would not act peripherally, but the author answers this criticism in his preface, stating that although this book was written in the spirit of optimism and skepticism new ideas were not only presented without fear but encouraged. Because of its wide scope, this publication should prove stimulating to specialists in all branches of medicine.

Milk and Milk Products Prepared for the Use of Agricultural College Students. By Clarence Henry Eckles, D.Sc., Willes Barnes Combs, M.A., Professor of Dairy Husbandry, University of Minnesota, and Harold Macy, Ph.D., Professor of Dairy Bacteriology, University of Minnesota. Second edition. Cloth. Price, \$3.50. Pp. 386, with 92 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1936.

The second edition of this welcome textbook on milk and milk products continues the reputation earned by the earlier edition. The book is primarily designed as a textbook for students in agricultural colleges; it therefore contains much material that could well be omitted for medical readers. Despite this duplication, which is necessary to preserve the functions for which the book is intended, the volume affords a mass of information on milk and dairy products that will interest the physician and the general reader. There are chapters touching on common dairy processes, the manufacture of butter, cheese and ice cream, and the methods of preparing evaporated milk and dry milk. There is no mention in the book of curd tension and methods of determining this property, nor is there any discussion of milk that has been treated to modify the curd.

Hígado, vías biliares y páncreas. Por el Doctor Marcelo Royer, jefe de la sección gastro-enterología del Instituto de Semiólogía. Paper. Pp. 132, with 49 illustrations. Buenos Aires: "El Ateneo" Librería científica y literaria, 1936.

Royer's book contains nineteen chapters in which the symptomatology of liver, biliary and pancreatic diseases and the several methods of examination of these structures are described. Certain methods and maneuvers for palpation in liver and biliary diseases are shown by illustrations. The diagnostic value of the methods of palpation to which the author refers is discussed. The aspect of the abdomen in certain conditions of the pancreas is shown by illustrations. The diagnostic significance of several roentgenograms of the liver, the biliary tract and the pancreas, which were taken in several aspects by the indirect and direct methods of visualization of the structures and which are shown in the book, is discussed in detail. Modern technics for roentgen examination of the biliary tract are given in detail and the diagnostic value of the technics is discussed. Functional tests for the liver, tests for biliary and hepatic secretions and functional tests for the pancreas are covered. The illustrations are clear.

Nutritive and Therapeutic Values of the Banana: A Digest of Scientific Literature. Paper. Pp. 143. Boston: Research Department, United Fruit Company, 1936.

The Research Department of the United Fruit Company has scoured the literature of scientific and clinical articles on the use of the banana as a food. The present volume is a compilation of 292 abstracts listed alphabetically according to authors. There is a subject index but no author index.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Practice of Dentistry Under Assumed Name Unlawful.—The dental practice act of Michigan forbids the practice of dentistry under any false or assumed name, or under the name of a corporation, company, association, parlor or trade name, or any name other than that under which the license of the practitioner was granted. The state board of dentistry served written notice on a number of dentists informing them that on and after a certain date the prohibitions contained in the dental practice act would be enforced. The plaintiffs in the present action, all licensed dentists, instituted proceedings to enjoin the board from interfering with their practice. The trial court dismissed the plaintiffs' bill of complaint and they appealed to the Supreme Court of Michigan.

The bill of complaint disclosed that plaintiff Raymond H. Dix conducted five dental offices in Michigan under the name of "Dr. Dix Dentists." Five other plaintiffs used substantially the same modification of their respective names. Plaintiff Treverton E. Lewis practiced dentistry under the title of "Peerless Dentists." Plaintiff William G. Zieve operated four dental offices under the style of "Dr. Zieve's Modern Dentists." The business of plaintiff J. Bain McGilvray was carried on under the name of "Red Cross Dentists," and that of plaintiff Gordon B. Sullivan under the name of "Dr. G. B. Sullivan's Practical Dentists." The plaintiffs contended that the dental practice act, if it prohibited them from practicing dentistry under the titles they used, was unconstitutional. The legislature, said the Supreme Court, in enacting the dental practice act, undertook to provide conditions essential to regulation, to prevent deception, and to require a definite and accurate announcement to the interested public as to the individual identity of each dentist who was practicing in a dental office. To accomplish this end, it prohibited the practice of dentistry by any person "under any name other than that under which his license was granted." Such a prohibition does not impose on those practicing dentistry a regulation that is either arbitrary or unreasonable. The provision is reasonably suited to the requirement of proper supervision of the practice of dentistry. It also provides prospective patients with pertinent information. Clearly, the court thought, it is both competent and proper that the legislature should forbid the practice of dentistry under an assumed or fictitious name, such as "Peerless Dentists," "Red Cross Dentists," "Dr. G. B. Sullivan's Practical Dentists," and "Dr. Zieve's Modern Dentists." The court could see no hardship or anything that was arbitrary or unreasonable in requiring a person engaged in the practice of dentistry to include in the name under which he carries on his profession the identical name under which he was licensed to practice. The legislature further prohibited the use of any word or words as a part of the business name which are either "false" or "assumed." In the opinion of the court, it would be too narrow a construction of legislative intent to hold that the use of a name, otherwise conforming to statutory requirement, was violative of the act because it had affixed thereto some such word as "dentists," "associates," "employees," or the like. The appended word or words, in such a case, would not convey a false impression or mislead the public. It would not be contended, the court said, that John Doe, a dentist, might not in his practice use the business title "John Doe, Dentist." If he employed other dentists in his office, a sign reading "John Doe, Dentists" would tend to accuracy and be informative rather than deceptive. If John Doe desired to convey to the public that other dentists in his office were his employees and hence under his control as to quality of service, etc., he might well carry on his profession as "John Doe's Dentists." Such a designation speaks the truth. It is not a false or assumed name, nor a "parlor or trade name"; it accurately discloses the full name under which John Doe was granted his license.

The court disagreed with the plaintiffs' contention that they had a vested right in their respective business titles, accrued

to them from a long established professional business and the expenditure of large sums of money in its development. A dentist enters on the practice of his profession, the court pointed out, knowing it is subject to reasonable regulation by the state. He has no right to use, or by reference to continue to make use of, a type of business title which in its exercise of reasonable regulation the state has forbidden. The Supreme Court disagreed with the board's contention that a court of equity has no jurisdiction to grant the injunctive relief sought by the plaintiffs, that each of the plaintiffs had an adequate remedy at law by urging as a defense his contentions in event of legal proceedings being instituted against him. The situation with which the plaintiffs were confronted, in the opinion of the court, threatened them with irreparable injury and a court of equity had jurisdiction.

With respect to some of the plaintiffs, the court could not determine from the record whether or not the names under which they were carrying on their profession complied with the requirements of the dental practice act. In view of this uncertainty, the court remanded the case to the trial court, with directions to set aside the order dismissing the bill of complaint and to take such further proceedings as might be requisite for a final disposition of the cause.—*Lewis v. Michigan State Board of Dentistry (Mich.)*, 269 N. W. 194.

Tic Douloureux Attributed to Trauma.—The plaintiff fell from a loading chute on a gravel car when one of the pipes which supported it was struck by a passing freight train belonging to the defendant railway company. Among other injuries, he sustained a bruise on one cheek. Subsequently, he suffered intense pain in the side of the face that had been bruised and a diagnosis of tic douloureux was made. Eventually the plaintiff sued the railway company to recover damages for his injuries. The trial court entered judgment for the plaintiff for \$2,000 and the railway company appealed to the court of civil appeals of Texas, Austin.

According to the medical testimony, said the court, tic douloureux is an affection of one of the facial nerves, incurable except by an operation which would result in paralysis of the side of the face and permanent injury to the eye. The medical testimony was conflicting as to whether the tic douloureux was the result of the plaintiff's injuries received from the fall. One physician testified that the medical profession generally was unable to ascribe any cause for tic douloureux. Two other physicians were of the opinion that it could be caused by a blow such as the plaintiff had received and the jury, said the court, evidently accepted the testimony of these two witnesses. The amount of damages awarded, \$2,000, was in the opinion of the court a moderate compensatory award for the plaintiff's pain and suffering, past and prospective. The judgment in favor of the plaintiff was affirmed.—*Texas & N. O. Ry. Co. v. New (Texas)*, 95 S. W. (2d) 170.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

- Somatic Phenomena in Psychoneuroses. J. M. Flynn, Boston.—p. 548.

Plasma Prothrombin in Normal Infancy and in Hemorrhagic Disease.—Brinkhous and his associates studied the plasma prothrombin level in a number of pregnant women and found no significant deviation from that of nonpregnant women. Two cases studied shortly before delivery showed values of 100 and 93 per cent of the nonpregnant control. Three, each taken a few minutes after delivery, were 110, 99 and 98 per cent. It is evident that the fetal prothrombin level lacks the stability of that of the mother and that the two levels are not related in any simple way. The plasma prothrombin level in infancy was studied with the aid of a quantitative titration procedure. The level in normal new-born babies varies in this series between 14 and 39 per cent of the level found in normal adult plasma. The prothrombin level rises gradually during subsequent months and reaches the adult level at the end of about a year. After the first few weeks of life the individual cases show little deviation from the curve plotted through the entire group. A case of hemorrhagic disease of the new-born showed the plasma prothrombin to be less than 5 per cent of normal adult values. The antithrombin activity of the plasma was somewhat excessive, but the plasma fibrin was normal. Intravenous transfusion of blood resulted in prompt cessation of bleeding. The plasma prothrombin studied ten and forty-four days later was found to be up to the normal values for infants of that age.

Inadequate Treatment of Early Syphilis.—Rosahn discusses the outcome in 409 patients who had received early inadequate treatment for syphilis. With regard to the diagnosis when treatment was begun, the highest proportion of

satisfactory results (no evidence of syphilis as determined by clinical, serologic and spinal fluid tests one year or more after the last treatment) was noted in the seronegative primary stage. A significantly higher incidence of satisfactory results was observed among patients who had received continuous treatment than in those treated by other systems. The least successful treatment was in patients receiving less than fifteen injections of a trivalent preparation and ten injections of bismuth or mercury compounds. It was best in those treated with these amounts or more. Syphilis of the central nervous system comprised the largest proportion of late relapses. Wassermann recurrent late syphilis had a slightly lower incidence and cardiovascular syphilis still lower. Early infectious relapse and late benign and visceral syphilis had an equal and also the lowest incidence. The 134 patients with a satisfactory result were followed for from one to thirty years after the last treatment; 117 of these had been observed for periods longer than two years after the cessation of specific medication. The most serious danger confronting these patients was the possibility of subsequently developing cardiovascular recurrence. Although inadequate treatment does produce a certain proportion of successful results, adequate treatment schemes as recommended by the Cooperative Clinical Group and by the Health Organization of the League of Nations should be rigorously followed in the management of early syphilis.

Visual Sequels from Meningococcal Meningitis.—Heath carried out medical, neurologic, ophthalmic and otologic examinations in sixty-eight cases selected because of a high proportion of complications 25.9 months after epidemic meningococcal infection. Ophthalmic and otologic examinations were made in twenty-five additional unselected cases 82.68 months after the epidemic. The medical examinations showed enlarged livers, spleens and hearts in from 5.8 to 8.8 per cent of the sixty-eight cases; other persisting complications were comparatively infrequent. The neurologic manifestations remaining after the acute stage of the disease were especially pronounced and severe in the personality field. These increased with the selected increase of other complications. The visual sequels averaged 16.1 per cent in ninety-three cases and were divided into muscular disturbances, 7.5 per cent; pupillary disturbances, 2.15 per cent; endophthalmitis, 4.3 per cent, and changes in the fundi, 2.15 per cent. Many complications of the eye in the acute stage of the disease were fugitive, but those persisting apparently had been acquired early in the disease. Loss of hearing, total and partial, was a most frequent and serious complication, and in the selected cases the visual sequels increased, but not proportionally with the auricular. Allowing for the higher proportion of complications in the patients who returned to the hospital because of their availability, the visual residue was less than 10 per cent. One is led to the conclusion that most of the visual damage in this disease is done early, during the overwhelming septicemia and toxemia, and that a continuing process is relatively uncommon.

- Some Neural Components of Visual Response. C. A. Elsberg and H. Spontitz, New York.—p. 792.

Blood Sugar Raising Substance in Urine.—The so-called diabetogenic substance used in these experiments was prepared from the urine of six male and five female patients: four controlled and two uncontrolled diabetic patients taking insulin, two controlled diabetic patients not taking insulin and three nondiabetic patients. In each case the product was tested on three rabbits and three dogs, which had been previously starved for twenty-four hours. Since the material remaining in the urine after the removal of the protein gave a blood sugar rise in the animals used, it was evident to Werch and Altschuler that they were not dealing with a protein reaction. Their results are in accord with those of Houssay and his collaborators; namely, that the blood sugar raising substance is easily adsorbed, soluble in water and in 60 per cent alcohol and insoluble in fat solvents. It does not pass through ultrafilters and boiling destroys its activity. The experiments performed on the factor furnished by normal urine showed that it is present in nondiabetic urine, if at all, in small quantities, since the resulting blood sugar rise is within the limits of experimental error. From those experiments performed on the factor obtained from the urine of controlled diabetic patients taking insulin, one may conclude that it is present in considerable quantity. The factor prepared from uncontrolled diabetic patients taking insulin gave readings much like those obtained by the substance of the preceding group. The blood sugar rise given by the factor prepared from controlled diabetic patients not taking insulin is not as great as that given by the factor prepared from controlled and uncontrolled diabetic patients taking insulin, in whom the diabetes was obviously more severe. However, the rise is greater than the expected experimental error and hence the substance may be considered present even if only scantily.

Relation of Bovine Mastitis to Human Disease.—The observations of Brooks and Tiedeman support the belief of others that the organisms responsible for cases of mastitis asso-

ciated with outbreaks of septic sore throat and scarlet fever are always of human origin; i. e., their source is persons, usually milkers, with infected throats or, occasionally, wounds. In their laboratory the organisms clearly responsible for epidemics usually have not shown the characteristics of the so-called *Streptococcus epidemicus*. The streptococci agalactiae and mastitidis usually associated with mastitis are commonly regarded as harmless for man. However, their toxins, in milk from cows with mastitis, apparently have been responsible for outbreaks of gastro-enteritis. Similar organisms have been isolated in cases of low grade infection in man and in fatal cases of uterine infection. The authors know of no evidence that relative general freedom from mastitis, as reported in the South, offers any protection against accidental infection with human organisms. The general control of mastitis, if feasible, probably should be considered primarily an economic problem of the dairy industry. There is nothing in the physical condition in such a case of mastitis to differentiate it from the ordinary types of mastitis, and careful laboratory studies ordinarily are made only in the presence of an epidemic. There is evidence suggesting that organisms commonly present in mastitis may invade human tissues. Pasteurization destroys all these organisms and probably their toxins as well, but when milk is being sold without pasteurization all cases of mastitis should be regarded as potentially dangerous and milk from any cow suffering from the disease should be excluded.

"Surgical Shock" Factors in Pneumonia.—Andrews and Harkins observed the weight of the lungs and the presence of pleural fluid in twenty-three cases of lobar, terminal or bronchopneumonia coming to necropsy. The average excess weight of the lungs in these cases (assuming normal lungs to weigh 600 Gm.) represented 2.45 per cent of the body weight. In several instances there was appreciable pleural fluid. This brought the total increase to 2.81 per cent of the body weight. No chemical analyses were performed, but if this amount represents blood or blood plasma it is of considerable significance and a condition resembling surgical shock may result. The lungs of two distemper and one pneumonia dog were analyzed chemically and compared with those of a normal dog. The analyses show that the nitrogen and protein content in abnormal lungs is essentially the same as in normal lungs, indicating that the pneumonic exudate contained protein. In certain instances different portions of the lung (right or left side) were markedly edematous without corresponding dilution of the protein content.

Encephalitis Due to Undulant Fever.—McCullagh and Clodfelter report four cases of encephalitis, in one of which features highly suggestive of hypothalamic and pituitary damage were present. In all the cases the agglutination test or skin test indicated that undulant fever was present and in none were other etiologic factors demonstrated. The relationship between encephalitis and undulant fever was suspected in the first case and this was proved as far as was practicable. In the second case the diagnosis of encephalitis was made ten

months before undulant fever was suspected as the etiologic factor. In the third case, decreased menstrual flow was associated with somnolence and other evidence of hypothalamic damage. The etiologic factors have apparently been the organisms of undulant fever as determined by agglutination tests in two cases and by intracutaneous tests in the other two cases. Two patients have shown improvement without specific treatment. The third patient failed to improve without specific treatment but showed some improvement following specific treatment. While there is improvement at present in the condition of the fourth patient, the prognosis seems uncertain in view of the history. While the authors realize that the evidence presented does not constitute proof that encephalitis in these cases was actually caused by the growth of *Brucella melitensis* in the perivascular spaces or nervous tissue of the brain and cord, the observations are nevertheless highly suggestive.

Rapid Hyposensitization.—Waldrott and Ascher believe that rapid hyposensitization deserves a definite place in the treatment of allergic diseases. Particularly in the severe asthmatic patient in whom the causative antigens are known, it has proved to be the method of choice. Successful treatment by this method is dependent on the administration of the proper antigen or combination of antigens; i. e., those which form the patient's dominant sensitivity. The danger of causing constitutional reactions or of aggravating existing symptoms can be obviated if one abides by the following principles: 1. The initial dose should be sufficiently low so as not to produce much local swelling. 2. The doses and intervals between treatments should be carefully gaged for each individual injection, the principal guide being the degree of local edema which is produced by the previous one. 3. An incipient constitutional reaction, which may merely manifest itself by a temporary aggravation of existing symptoms, should be recognized and carefully guarded against by a readjustment of the proposed schedule of treatment. 4. No epinephrine, or as little as possible, should be used in conjunction with the treatment in order not to interfere with the production of a local swelling.

Endocarditis Caused by *Bacillus Diphtheriae*.—Buddingh and Anderson cite a case of acute vegetative mitral endocarditis. Morphologically and culturally the organism isolated from the spleen, heart blood and mitral vegetation in this case belonged to the group *Corynebacterium*. Intracutaneous tests in guinea-pigs with a twenty-four hour broth culture and the filtrate of a seven day broth culture produced reactions typical of *Bacillus diphtheriae*. Subcutaneous and intraperitoneal inoculations of the twenty-four hour broth culture caused death in an animal within three days. The administration of standard

diphtheria antitoxin by the standard method protected guinea-pigs against the effect of the organism. These observations prove that the organism isolated from the mitral valve was a true strain of *Bacillus diphtheriae*. The port of entry in this case most likely was an ulceration of the nasopharynx, which was caused by the prolonged packing necessitated by continuous nosebleeds. The mitral valve, previously damaged by rheumatic disease, apparently provided a favorable lodging place for the organism, which gained entry to the blood stream from the ulcerated nasopharynx. From here embolic lesions were set up in the heart, intestine, kidneys, skin and mucous membranes. The endocarditis was rapid and fulminating, lasting for only five days.

Significance of Bacteremia in Pneumococcal Pneumonia.—Tilghman and Finland consider 1,586 cases of pneumonia associated with specific pneumococci of types I to XXXII (Cooper) in which cultures of the blood were made during the acute stage of the disease or at necropsy. For each type the death rate in the cases in which the blood cultures were positive was two or more times as high as in the cases in which the blood cultures were sterile, and for all types it averaged almost three times as high. Positive results of blood cultures were obtained in slightly more than a third of all the cases. The incidence of bacteremia varied widely in the cases of different types and was highest for the cases of pneumonia due to type II pneumococci. In the fatal cases the incidence of bacteremia was four times as great as in the nonfatal cases, and this proportion was even higher when the cases in which serum treatment was given were excluded. The mortality rate increased progressively with the ages of the patients, this being true for patients both with and without bacteremia. The greater mortality for bronchopneumonia was found for each type, both with and without bacteremia. Bacteremia, however, was less frequent with most types of atypical pneumonia. The death rate was higher in the cases in which the greater amount of lung was involved. There was little difference in the incidence of bacteremia and in the death rate for nonusers of alcohol and for habitual drinkers. There was a significantly greater incidence of bacteremia in the cases of pneumonia which occurred in the course of other serious conditions or diseases (so-called secondary pneumonia) than in the cases of primary pneumonia. The differences in the mortality rate at different leukocyte levels varied in the same manner as the incidence of bacteremia. Bacteremia was most frequent in the cases in which the leukocyte count was below 10,000. It was higher in the cases in which the count was 35,000 or more than in those in which it was between 10,000 and 34,000. Bacteremia was more than twice as frequent in the cases in which there were postpneumonic complications as in those in which there were none. Conversely, the complications were more than twice as frequent in the cases of bacteremia as in the cases in which bacteremia was not noted. In the cases in which no specific serum was given, the termination of the acute disease by crisis, lysis or death occurred most frequently between the seventh and the ninth day. Sterilization of the blood stream without apparent improvement of the acute symptoms or in spite of progression of the pulmonary lesion occurred more frequently after serum therapy was given than in cases in which no serum was administered. For the bacteremic patients who recovered, the colony count was usually below 10 per cubic centimeter of blood. The prognosis was usually, but not invariably, found to be unfavorable when the number of colonies increased in successive blood cultures.

Atherosclerosis and Diets Rich in Vegetable Protein.—The studies of Freyberg on the relationship of vegetable protein to atherosclerosis are contrary to those of Newburgh and Squier with animal protein. Diets containing 33 and 37.8 per cent of vegetable protein fed to rabbits for as long as eleven months failed to produce atherosclerosis. Rarely were cholesterol values of the blood observed which were higher than the normal range. These were in every case associated with undernutrition and are thought not to result directly from ingestion of large quantities of vegetable protein. These data suggest that the atherosclerosis observed when rabbits were fed diets rich in muscle meat was due to a nonprotein constituent of this animal food.

Rôle of Allergy in Progressive Thrombosis.—Tannenber studied the influence of allergy on the development of thrombosis with a view to the significance of allergic endothelial changes in the veins. Three groups of rabbits were prepared by nine intravenous injections of antigen (pneumococci, streptococci and sheep serum, respectively). From seven to eighteen days later the right jugular and femoral veins in each animal were exposed and narrowed and an intravenous reinjection was made into the corresponding vein of the ear. Merely local thrombi were obtained, not larger than those in the nonimmunized controls. Only a single rabbit, which in addition presented progressive, widely spread chronic nephritis, showed a kind of progressive thrombosis. In the narrowed segments of the veins endothelial changes morphologically similar to active proliferations were observed. But the failure of the changes to show progression seven, twenty-four and forty-eight hours after the operations and the occurrence of similar changes in the controls showed that to interpret them as allergic, active endothelial reactions would be erroneous. Serial sections revealed that these changes were produced by folding of the endothelium in the narrowed segments, superficial degenerative changes of the endothelium and deposits of blood leukocytes at the injured areas.

So-Called Straddle Injury.—When a person falls astride an unyielding surface, such as a timber, the soft tissues and urethra of the perineum are commonly pinched. The force is transmitted to and brought to bear on the weaker and unfortified abutting membranous structure; i. e., the terminal membranous urethra. When extravasation is probable, one should consider the urethral perineum as being divided into three parts, to wit: (1) the area within the superficial perineal interspace, (2) that between the inferior and superior layers of the triangular ligament, or the urogenital diaphragm, and (3) that above or proximal to the superior layer of the triangular ligament. It is also necessary to take cognizance of a fourth area, concerned more often with rupture of the pendulous urethra; extravasation may take place between the layers of Buck's fascia. The vulnerable portion of the membranous urethra (the distal portion) lies in the superficial perineal interspace. That portion of the membranous urethra between the inferior and superior layers of the triangular ligament is sometimes involved in straddle injuries, particularly by puncture wounds. Any extravasation proximal to the superficial layer of the triangular ligament may seep backward into the ischioanal region and buttocks or into the thighs. The area above the superior layer of the triangular ligament is seldom concerned in these accidents save by puncture wounds. Beach's article is based on sixteen straddle injuries seen in the last twelve years. In analyzing the clinical material he

discusses it under the following subheads: urethral injury, preexisting urethral strictures, urinary retention, perineal appearance, bleeding from the penis, pain and tenderness, shock, complications and sequels. The fundamental objective in treatment is to divert the urine from the site of urethral injury and, incidentally, in many cases to relieve acute urinary retention. There are three avenues of approach, used singly or in combination: the catheter, external urethrotomy and cystotomy. In every case of urethral rupture, whether the rupture is partial or complete, the patient should be hospitalized. Each patient is a law unto himself and must be handled accordingly. Many patients with partial ruptures, when catheterization is possible, do well and have no complications when an indwelling catheter is used. If catheterization is impossible, simple and direct surgical intervention must be undertaken without delay. Surgical treatment must not be too extensive at one session. It is better to drain the urine and give the patient a few days of rest, after which one is agreeably surprised at the ease of subsequent accomplishments.

Rib-Splinter Graft for Vertebral Tuberculosis.—During the last few years Petter has performed osteosynthesis of the spine in thirty individuals with tuberculosis of the vertebrae, employing the operative technic described by Henry and Geist and including fusion of the vertebral articulations recommended by Hibbs. Practically all of this group, at the time of operation, had been confined to bed for many months because of the complexity of the lesions. In the entire series the operative mortality was zero. However, one disquieting event did occur in almost every case: when the bone chips for the graft were removed from the tibia a state of shock developed when the hammering was begun. Because of this complicating factor, the rib was used instead of the tibia. The preparation of the graft bed was carried out in the same manner as before, but the rib graft was placed in the form of splinters. Three cases have been so treated, and, although the postoperative period of observation is relatively short (five, four and three months), the author feels that the results warrant a report. Since most patients with vertebral tuberculosis must be treated by pro-

longed recumbency, immediate strength of graft is not of importance. Therefore, solid rib or tibial grafts, anchored to the laminae and the spinous processes, are not, in the author's opinion, of as much value as a graft which in itself will resist little if any strain, but which later develops into a thick plate of solid bone, extending well out on the laminae laterally and from the spinous process of the second or third healthy vertebra above and below the diseased area. Solid cortical grafts, then, present immediate strength but a low-grade proliferative power, while rib splinters, composed of fine periosteal shreds, cortex and endosteum, possess a high degree of osteogenic ability, although they offer little early support.

Pulmonary Moniliasis.—Davis and Warren review the literature and cite a fatal case of pulmonary moniliasis due to *Monilia albicans*. The strain of *Monilia albicans* isolated from the sputum of the patient was subjected to different environments and the reactions on nutrient broths, each containing 1 per cent mannose, maltose, dextrin, lactose, dextrose, galactose, mannite, saccharose, levulose, dulcitol, rhamnose, arabinose and xylose were determined. Their observations definitely prove that the reaction of this strain of *Monilia* was constant on all the sugars. *Monilia* was found to be pathogenic for rabbits when injected intravenously and for white mice when injected subcutaneously or intraperitoneally but was not pathogenic for guinea-pigs when 1 cc. of sputum containing the organisms was injected intraperitoneally.

- Multiple Nature of Vitamin D of Fish Oils.**—Bills and his co-workers compared the liver oils of twenty-five species of fish with cod liver oil by assay on rats and chickens. The relatively least effective oils were those from bluefin tuna

of California, oriental tuna, striped tuna, bonito, albacore and totuava. The relatively most effective oil was that from the white sea bass of California. The maximum observed difference in relative effectiveness was about eighteen times, a difference much greater than the probable errors of assay. The differences were due to the existence of two or more forms of vitamin D in the oils. The possible relation of the vitamin D in the fish oils to certain artificial forms, particularly viosterol and irradiated 7-dehydrocholesterol, is discussed. The relative effectiveness of viosterol was lower than that of any fish oil, about the same as that of cod liver oil or irradiated ordinary cholesterol but inferior to that of white sea bass liver oil. Oils of related species, particularly the several tunas, differed widely in relative effectiveness.

Chronic Toxicity of Dinitrophenol.—Schulte administered alpha dinitrophenol orally to dogs for periods of 175 days in doses up to 26 mg. per kilogram daily. The doses, which were sufficient to produce subacute poisoning and eventual death, did not demonstrably affect the function of the liver as indicated by galactose and uric acid tolerance tests. Pathologic examination revealed no lenticular opacities, and the livers were essentially no different from those of unmedicated dogs kept under similar conditions. These results confirm and extend previous negative results and show that continued medication with high doses of dinitrophenol does not result in dogs in demonstrable impairment of the functional capacity of the liver according to a variety of tests.

- Phrenic Interruption in Treatment of Tuberculosis.**—Potter and his associates relate their observations in ninety-five cases in which phrenic interruption was performed and

which were followed from one to five years postoperatively. The operation was used as an independent procedure in sixty-eight cases, as a supplement to ineffective pneumothorax in twelve and for miscellaneous reasons in fifteen. The contraindications for diaphragmatic paralysis are huge cavities, thick-walled cavities and cavities embedded in a fibrous infiltrate, peripherally located adherent cavities, lesions within a lung surrounded by a thick pleura, and multiple cavities. Favorable results can be expected in small or moderate-sized cavernous lesions with a surrounding zone of lung tissue more or less free of infiltrate. A cavity within a shrinking lobe which has ceased to contract further is an indication, provided the infiltrative process about the cavity is not extensive and provided the latter has shown diminution from the original size along with the contraction of the lobe. Of the sixty-eight cases in which the operation was used independently, thirty-eight were found suitable in retrospect. Closure of the cavity occurred in 47 per cent of this group and reduction in the size of the cavity with general clinical improvement in 31 per cent, and thoracoplasty was spared in 15 per cent. The average interval between operation and closure of the cavity was seven and one-half months. While the authors do not advocate the procedure unless it is definitely indicated, nevertheless they suggest that, in borderline cases, in which thoracoplasty is dangerous, a temporary interruption may turn the tide for the patient and make thoracoplasty possible. The operation, when used as a supplement for ineffective pneumothorax in selected cases in which there is a bow string effect, offers about 50 per cent success. The reduction of the intrapleural space is the chief indication for the miscellaneous uses of phrenic interruption.

One-Stage Pneumonectomy Under Local Anesthesia.

—Burnett describes a case in which pneumonectomy was successful and outlines the technic and the local anesthesia that he used for the procedure. The technic of the anesthesia was developed from extension of the field block technic for rib resection in the treatment of empyema and partial thoracoplasty. It consists of the use of 0.5 per cent procaine hydrochloride in saline solution to produce a series of wheals over the intercostal spaces, from the second to the tenth or eleventh, at the edge of the erector spinae muscle. After the first, these are made painlessly from beneath the skin. Through these wheals, injections of about 5 cc. of 1 per cent procaine hydrochloride are made into the appropriate nerves. If the incision is to be carried to the midline anteriorly, the crossed innervation from the opposite side has to be interrupted by a band of procaine hydrochloride at this point. Towel clips, used in the upper pectoral region, require additional local injection into each spot. Ten minutes after the last injection, the anesthesia is checked by the needle and finger method. If it is not complete, injections are again made into the nerves which have not been interrupted. When the chest is opened, inhalations of carbon dioxide and oxygen under pressure may be necessary to prevent sudden complete collapse. They are unnecessary if pneumothorax has previously been instituted or if the lung is extensively adherent. The injection made into the phrenic nerve in the thorax, when it is exposed, interrupts the sensory and motor diaphragmatic innervation. The pulmonary ligament and the hilus of the lung are sensitive areas, and 1 per cent procaine hydrochloride has to be injected into them. Pouring 1 per cent procaine hydrochloride over the pleura and maintaining its application with a gauze sponge saturated with the solution while one is dissecting adhesions or exploring the remainder of the thorax produces insensitivity there also. Children have been prepared by the preliminary injection of fairly large amounts of morphine in divided doses and adults by the use of one-sixth grain (10 mg.) of morphine supplemented by rectal injection of tribrom-ethanol, from 40 to 60 mg. per kilogram, depending on the type of person. Under these circumstances, the cough reflex is not abolished, although it is definitely decreased. The disadvantages of this method are the same as those for most operations with local anesthesia. The advantage is that for the same procedure the amount of shock is greatly decreased or a more extensive procedure is possible, at a one stage operation, than is possible with anesthesia by inhalation. The difficulty of certain complicated types of administration of anesthesia are avoided. The operator is able to work accurately and without haste; the cough reflex

for expulsion of pus or blood as the lung is manipulated is maintained, and there is considerable improvement in immediate postoperative convalescence.

Exstrophy of the Bladder.—Ladd and Lanman describe a three stage ureterosigmoidostomy that they used in fifteen cases of exstrophy of the bladder. The best time for the operation is between the ages of 3 and 5 years. The patient should have several days of hospitalization before the first operation. Intravenous pyelograms, determinations of the nonprotein nitrogen and tests with phenolsulfonphthalein should be made. The patient should have a low residue diet and should be given a saline solution enema daily. Dextrose should be given in generous amounts for forty-eight hours prior to the operation. Tribrom-ethanol, 80 mg. per kilogram, supplemented by gas and oxygen and a little ether, seems to be the anesthetic of choice. The clamped rectal tube, which is used for the administration of the tribrom-ethanol, is left inserted in the rectum. The exstrophied bladder is carefully walled off with sterile gutta-percha before the patient is draped. The right ureter is transplanted first. It is freed from its bed down almost to the bladder, where it is tied and cut off with the actual cautery or with an electric knife, and the distal end is allowed to drop back behind the peritoneum. The sigmoid is then brought over so that the proper position of the line of implantation can be judged. This should be made so that its proximal end will lie close to the proximal end of the freed ureter as it leaves its retroperitoneal bed. The rectal tube is then unclamped, the sigmoid is milked to express gas and liquid contents, and right angle intestinal clamps are applied. An incision through the serous and muscular coats in the line previously ascertained is made for from 2½ to 3 inches (6.2 to 7.6 cm.). The ureter, with a temporary, inflying catheter, is placed on this submucosa in such a way that it will not kink. A sufficient amount of the ureter is cut off so that, when it is in place, it is neither on tension nor kinked. A longitudinal cut is made in the posterior wall of the ureter to prevent its orifice from

ever becoming constricted. A double-ended suture is placed in the end of the ureter from within outward to evert it. The mucosa of the intestine is opened with the electric knife and the ureter is carried into the lumen of the sigmoid by the double-ended suture, which pierces all layers of the bowel from within outward and is tied holding the ureter in place. The two rows of sutures are next completed. The sigmoid is next stitched with interrupted silk stitches to the medial side of the peritoneal incision that exposed the ureter. When this step is completed the lateral side is stitched, making the whole line of anastomosis extraperitoneal. The abdominal wound is closed without drainage. Two weeks or so later the left ureter is implanted into the sigmoid in a similar manner. The site of the second transplant can be chosen higher up in the sigmoid so that neither the sigmoid nor the two transplants will be kinked or strained. The administration of large amounts of fluid after the operation is essential. The extrophied bladder should be removed by an elliptic incision made in the skin close to the mucous border and the dissection of the mucous membrane and part of the musculature. The dissection is carried down to a point in the region of the verumontanum, in the male, so as to save the ejaculatory ducts. The resulting space may be largely covered by suturing the edges of the anterior rectus fascia together and by closing the skin over these edges. In the male a plastic operation on the epispadias should be performed later. In the female the vagina, uterus and adnexa are usually present and normal. In the authors' series no mortality followed the cystectomy, and herniation through the cleft abdomen has not been a matter of concern. In fourteen of the fifteen cases, urine appeared within forty-eight hours and usually within twenty-four hours after the initial transplant. Control of the intestine for from three to four hours during the day was obtained in nearly all cases within three weeks or less after operation.

Importance of Kidney Function in Alkalosis.—Berger studied seven cases in which there were definite symptoms and chemical evidence in the blood of alkalosis following intensive use of alkali in the treatment of peptic ulcer. None of the patients gave a previous history of nephritis. Mild to moderate anemia was present in each case except two. Treatment consisted in some cases of either discontinuing the administration of alkaline powders or reducing the amount. In the rest tribasic calcium phosphate and, in one case, mucin were substituted as needed for the relief of distress. Fluids were forced by mouth, and a 10 per cent solution of dextrose and 1 per cent saline solution were administered intravenously. Operative procedures were subsequently carried out on four patients. Studies of the renal function were carried out on each at the time alkalosis was first diagnosed. One week or more later, when the blood urea and carbon dioxide were normal, renal studies were again repeated. After the alkalosis was relieved, evidence of impaired renal function was found to be present in two patients. The other two had normal renal function. The possibility of alkalosis in the treatment of peptic ulcer should be kept constantly in mind. The phenomenon usually comes

on gradually. Apparently no relation exists between the amount of alkali ingested and the onset of alkalosis. The symptoms of distaste for milk, the patient claiming that it is sour, of headache and of weakness are constant, and they occur early. They are noted in the period of compensated alkalosis prior to the characteristic changes in blood chemistry that follow. Unless these symptoms are appreciated and the condition recognized, the condition will progress and may go on to convulsions and even coma. Impaired renal function was demonstrated in all the cases during alkalosis. The status of the kidneys should be determined in each case before the patient is placed on alkaline powders. The renal excretion of sulfates is a sensitive index of renal function. It is not implied that alkalosis cannot occur unless there is previous renal injury but rather that in the presence of renal insufficiency the threshold of safety is less, and not only that alkalosis is produced more easily in the presence of a preexisting renal injury but also that renal injury is increased concurrently with alkalosis, a vicious cycle being set up. Neither basic nor acid salts can be administered with impunity in the presence of renal impairment. In the presence of normal renal function, the buffer mechanism maintaining the acid-base equilibrium can absorb the assault of either acidifying or basic salts with little or no variation. The liver plays an important part in maintaining the acid-base equilibrium and in the presence of hepatic insufficiency is disturbed much more easily, as is evidenced by the intolerance in cases of cirrhosis to ingestion of either acid or basic salts.

Hysterosalpingography in Gynecologic Diagnosis.—Mathieu believes that hysterosalpingography is as valuable and as welcome as visualization of the bronchial tree or the urinary

tract. Few untoward effects have been reported in the literature; most of those that have been reported were due to faulty technic. If one uses good technic and avoids the maneuver in the presence of active infection or normal pregnancy, it offers a maximum of results in diagnosis as it pertains to the cavities of the uterus and tubes with a minimal amount of discomfort. If more hysterosalpingograms are taken, fewer hysterectomies will be performed when curettage will suffice, and fewer curettages will be done when hysterectomy is necessary. The most valuable field for hysterosalpingography is in the study of sterility, wherein it is important to decide whether or not the tubes are patent and to determine the position and the nature of obstructions. In several of the author's patients, pregnancy followed soon after the injection of iodized oil when this was the only procedure done that might have had a corrective value. In such cases it is reasonable to assume that the tube was actually opened in some way by the process.

Carcinoma of the Bronchus.—Clerf declares that if there is to be any advance in the surgical treatment of bronchial carcinoma it will depend almost entirely on arriving at a correct diagnosis early in the disease. This responsibility rests primarily with the clinician, who should be "cancer of the bronchus minded" as well as "roentgen-ray minded." When cancer is a diagnostic possibility, it is important to arrive promptly at a diagnosis. No group of symptoms or signs can be considered diagnostic of carcinoma; they are dependent on the location of the growth and its influence on adjacent structures. The early symptoms are important, as their correct interpretation will lead to early diagnosis. A diagnosis made when the carcinoma is advanced is of statistical value only; from the patient's standpoint it is of little or no importance. Cough with or without sputum has been the most common early symptom of carcinoma involving the larger bronchi. If associated with blood-streaked mucoid sputum in the absence of tuberculosis, it is highly suggestive of bronchial neoplasm. A wheeze in conjunction with cough and occasional blood-streaked sputum or absence of sputum constitutes strong evidence that new growth is producing early partial obstruction to a bronchus. Pain is not a common early manifestation of carcinoma originating in the larger bronchi. It is, however, considered "the most common signal symptom" of peripheral carcinoma and is due to peripheral extension of the growth to the pleura and extrapleural structures. Dyspnea, pleural effusion, loss of weight, weakness, fever and sweats, dysphagia, hoarseness, pupillary changes and engorgement of the veins of the neck and chest are commonly evidences of advanced disease and are principally of didactic interest. Difficulty in diagnosis is encountered in cases in which the changes are suggestive of tuberculosis, pneumonitis, bronchiectasis or pulmonary abscess without roentgenographic evidences of tumor or bronchial obstruction. Since more than 50 per cent of primary bronchial neoplasms originate in the larger bronchi, it is evident that in many cases during the early stages there is partial obstruction to a bronchus, with obstructive emphysema. Roentgenoscopic examination of the chest and a study of the roentgenograms made at the end of full inspiration and expiration aid greatly in the recognition of nonopaque foreign bodies in the bronchus and a knowledge of the mechanism of obstructive emphysema. Bronchoscopy is the most definite and positive diagnostic procedure available. One may obtain a direct endoscopic view of the growth; in addition, tissue may be secured for histologic examination. If no intrusion of growth into the bronchus can be visualized, one may observe evidences of infiltration of the bronchial wall, fixity and rigidity. The bronchoscopist should be given an opportunity to investigate endoscopically all cases of obstructive emphysema or obstructive atelectasis. Unexplained cough, hemoptysis and wheeze also warrant bronchoscopy.

Malignant Growths of Nasal Accessory Sinuses.—Lederer believes that a malignant neoplasm of a nasal sinus is seldom if ever confined within a mathematically calculable area. By virtue of the characteristically slow growth of a neoplasm within a bony cavity it is observed as such at a time when it falls within the classification of inoperability; that is, when the diagnosis finally becomes self evident. Unfortunately, inspection, auscultation and palpation, anterior and posterior rhinoscopy, endoscopy, transillumination, roentgen examination and biopsy do not always facilitate a conclusive diagnosis in early cases. Furthermore, confusing clinical pictures are produced by intercurrent or coexisting diseases, particularly by those which cause swellings about the maxilla and orbit. Syphilis and tuberculosis may obscure the diagnosis of cancer, thereby delaying proper therapy. Peculiar histologic responses of the various tissues to tumor growth and infection may also hinder a correct diagnosis. The development of sinus cancer is slow, metastasizing infrequently. There is a definite tendency of such tumors to invade the meninges and other intracranial structures. While the symptoms usually vary, in the main the points to be noted are unilateral nasal obstruction, mucopurulent or serosanguineous discharge, headaches (usually frontal), nasal hemorrhage, fetor, cranial nerve involvement consisting of sensory disturbances (neuralgic-like pains, paresthesia and anesthesia), ocular disturbances (proptosis, limitation of motion, papillitis and atrophy), olfactory disturbances (anosmia and parosmia) and external deformity. Surgery, electrosurgery and irradiation combined have given fair results in malignant tumors of the nasal sinuses, especially those of the antrum, in spite of the fact that 80 per cent have been termed inoperable because of invasion of vital structures. Malignant growths of the frontal sinus if seen in time may be operable, in which case the sinus should be exposed widely through the external route. Cosmetic results should not enter into consideration. As much of the mass is removed as is possible and the remainder is coagulated by surgical diathermy. If the dura is invaded, the frontal lobe is to be exposed fully. The skin flaps are sutured to one side and the wound is left wide open for contact radium applications. Radium may be used in this region with impunity because the dura is quite resistant.

Infectious Mononucleosis and Monocytic Leukemia.—Israëls describes a case of monocytic leukemia and contrasts its clinical and hematologic features with those of two notably dissimilar cases of infectious mononucleosis. Case 1 is typical of monocytic leukemia, case 3 is characteristic of glandular fever, while case 2 shows features of both. In characteristic cases, such as cases 1 and 3, the differential diagnosis presents little difficulty. The patient with acute leukemia is severely ill, there is marked anemia, and a high proportion of the leukocytes are recognizably immature. The patient with glandular fever has an illness which is clinically mild, there is no anemia of any significance, and although there is a mononucleosis only a small proportion of the cells can be interpreted as immature. In less typical cases the diagnosis may present great difficulty. Both conditions may show pyrexia, enlarged lymph glands and an enlarged spleen. Lesions of the mouth and sore throat, not part of a leukemic syndrome, may be accompanied by a mononucleosis. Case 2 shows that hemorrhage and anemia may occur in infectious mononucleosis as well as in leukemia; but the anemia of acute leukemia, except in the early stages, is usually more severe. The total white cell count is no guide; the majority of cases of acute leukemia have white cell counts of less than 40,000 per cubic millimeter and many are less than 10,000 per cubic millimeter. The morphology of the mononuclears is, however, usually very helpful, and this, together with the clinical impression of the illness, are the most useful points. The "heterophile antibody" tests introduced by Paul and Bunnell (1932 and 1933) also seem to be promising.

Posttraumatic Painful Osteoporosis (Sudeck's Atrophy). D. S. Middleton.—p. 115.

Obstructive Anuria.—Jacobs reports seven cases of obstructive anuria in which early recognition and treatment of the responsible lesion resulted in recovery. Five of these patients had previously been subjected to a nephrectomy, carried out for advanced calculus disease in four and for renal tuberculosis in one. In one of the patients spontaneous recovery ensued after expelling a stone from the left ureter: reflex anuria. In the seventh case, in which the anuria was apparently of traumatic origin, complete urologic investigation failed to establish the presence of a second kidney. Nephrostomy was carried out in five instances. In two this was a temporary measure, but in the other three the kidney was permanently drained by this method. During the last few years the author has found an increasing field of usefulness for this operation, not only in dealing with the crisis of anuria, but as a temporary measure of deviating the urinary stream when operating for such conditions as massive renal calculus, bilateral calculus disease and hydronephrosis.

Ossification of Human Frontal Bone.—Inman and Saunders give a historical review of the literature on the ossification of the frontal bone and its accessory centers. Observations were made on a total of ninety-eight fetal skulls ranging in age from the sixth week of intra-uterine life to the tenth month after birth. Primary centers of the frontal bone make their appearance in the superciliary region. No secondary centers of ossification have been found at any time in the frontal bone. The changes that have given rise to the error that such centers exist are considered. Attempts that have been made to homologize portions of the frontal bone with the prefrontal and postfrontal elements of premammalian skulls have been based on the presumed existence of secondary centers. As no such centers exist in the human skull, conclusions drawn on this basis must be discarded.

Study of Intestinal Flora of Children.—In a series of children operated on for simple appendicitis, Blacklock and his colleagues found that coliform bacilli and other organisms were practically absent from the upper part of the small intestine. Such results were also obtained from a necropsy series of nonseptic cases. In another group of children dying of parental infections, coliform bacilli were increased in the duodenum and jejunum but were less abundant than in primary acute gastroenteritis, in which the coliform incidence at these levels reached a maximum for the series. No specific infecting organism was

recovered from the gastro-enteritis cases, in which the lesions in the organs were of a toxic nature and those in the intestine usually inflammatory, though at times minimal in view of the clinical severity. The incidence of coliform bacilli in the small intestine appeared to be rather higher in infants than in older children, though the differences observed cannot be regarded as established on the figures available. In certain cases elevation of body temperature seemed to increase the incidence of coliform bacilli in the small intestine, but the observations generally showed considerable discrepancy. In acute enteritis the pH of the contents of the small intestine appeared to be slightly less acid than in normal subjects. Coliform bacteriophage was never found in the small intestine. Thus in primary gastro-enteritis the essential factor appears to be a breakdown in the normal physiologic functions, which maintain a relative sterility in the upper part of the highly absorptive small intestine. It is, however, the secondary pathologic conditions, largely toxic in nature, which dominate the clinical and postmortem observations.

Occurrence of Protective Antibodies in Syphilis.—Beck examined fifteen serums and two cerebrospinal fluids of syphilitic persons and three serums of syphilitic rabbits by a quantitative *in vivo* method for the presence of protective antibodies against the syphilis spirochete. No evidence of such antibodies was found. The negative result may be due to an insufficient specificity of the antigens used. If the syphilis spirochete varied in its antigenic structure as the relapsing fever spirochete or trypanosomes do, the failure to demonstrate antibodies might be due to the unsuitability of the antigens used. But, according to observation in man, it is not very probable that such a variability of different immunologic types of human syphilis spirochetes occurs. Unlike as in rabbits, immunity in man seems to be a "panimmunity" directed against all strains of syphilis spirochetes (Kolle, 1926). In view of the results obtained it is maintained that no protective antibodies are demonstrable in syphilis. This, and the lack of demonstrable antibodies by *in vitro* methods, reported earlier, render it improbable that immunity in syphilis is based on a humoral mechanism. It seems that, as in tuberculosis, the protection against superinfection or reinfection of the previously infected syphilitic individual depends solely on an altered mode of reaction of the tissue cell itself against newly introduced spirochetes.

Interference Phenomenon in Relation to Yellow Fever.—Findlay and MacCallum observed that rhesus monkeys inoculated subcutaneously or intraperitoneally with a mixture of neurotropic and pantropic strains of yellow fever virus survive, while control monkeys similarly inoculated with pantropic virus alone die. When the neurotropic virus is inoculated twenty-four hours after the pantropic virus, there is no protection. Intracerebral inoculation of monkeys with a mixture of neurotropic and pantropic yellow fever viruses results in death from encephalomyelitis: control monkeys inoculated intracerebrally with pantropic virus die with liver necrosis and other lesions in the viscera. The subcutaneous inoculation of men with yellow fever immune serum and mixtures of neurotropic and pantropic yellow fever viruses gives rise to reactions similar to those induced by the neurotropic virus, while those induced by the pantropic virus are absent. The evidence therefore shows that the neurotropic virus protects against the pantropic yellow fever virus, but the pantropic virus does not protect against the neurotropic virus. The subcutaneous or intraperitoneal inoculation of mixtures of pantropic yellow fever virus and pantropic Rift Valley fever virus in rhesus monkeys resulted in the protection of seven out of eleven animals. The intraperitoneal inoculation of mice with mixtures of neurotropic yellow fever virus and pantropic Rift Valley fever virus caused a delay in the death of the mice and in a small proportion of cases protected them completely. This protective action was not seen if Rift Valley fever virus was given twenty-four hours before the inoculation of the yellow fever virus. A possible explanation of the interference shown by the neurotropic strain of yellow fever virus with the pathogenic action of the pantropic strains of yellow fever and Rift Valley fever is that, when certain cells are already occupied by actively multiplying virus particles, they cannot be invaded by certain other virus particles.

Heart Disease with Normal Rhythm Complicating Pregnancy.—Harris has observed 100 pregnant women suffering from valvular disease of the heart with normal rhythm during pregnancy. Only three patients have been subsequently lost sight of; the remainder have been kept under observation for at least two years after delivery, and twenty of these have been followed up for four years or more. No patient died during the course of pregnancy or labor. In the management of such a case a careful investigation of the history of the patient's exercise tolerance before and during the early months of the pregnancy is of great importance. Early breakdown of exercise tolerance in a primipara is a grave sign, since death may occur soon after labor or congestive heart failure is likely to supervene with its attendant grave risks. In multiparous women the experience derived from the previous pregnancies is of great value, since the breakdown of exercise tolerance earlier and earlier in each successive pregnancy is a serious feature for the same reason. The subsequent mortality was greater in those patients in whom congestive heart failure occurred than in those in whom it did not, and particularly in the primiparas. When congestive failure developed early in the pregnancy the patients did well, possibly as a result of obstetric treatment; those in whom the failure developed late did badly, particularly if the failure had not cleared up at the time of delivery. A short interval between pregnancies increases the risk of congestive failure in a cardiac case. The incidence of premature delivery was increased in cases in which congestive failure developed during pregnancy, whereas it was not increased in the other cardiac cases. Patients with slight or no enlargement of the heart did better than those with moderate or considerable enlargement. There appeared to be no difference in the prognosis between cases of mitral stenosis, those of aortic regurgitation and those in which both these lesions were present. Pregnancy is contraindicated in those patients with heart disease with normal rhythm, who have ever had congestive failure, in whom the exercise tolerance broke down early in a previous pregnancy or in whom the heart is considerably enlarged. Termination by emptying the uterus should be undertaken as soon as the failure has been relieved by rest and other medical measures. During the pregnancy careful supervision and increased rest with admission to the hospital for at least two weeks before the onset of labor is advisable for the successful management of a case of heart disease complicating pregnancy.

Solitary Metastasis in Spleen in Carcinoma of Breast.—McMenemey cites a case of carcinoma of the breast with solitary metastasis in the spleen. The splenic tumor is the only abdominal metastasis and the only one which cannot be readily

explained on the basis of a lymphatic spread. The presence of this large growth in the spleen is further evidence against the view now partly discredited, but still upheld in part by Krumpholtz in 1927, that the spleen exerts a "specific antagonistic action" against carcinoma cells, a view in favor of which there has been some experimental work.

Acute Rheumatism and Rheumatic Heart Disease in New South Wales.—Maddox divides his article into three parts: the general incidence of cardiac rheumatism in South Wales, the distribution of rheumatic heart disease in rural South Wales and the distribution of rheumatic fever in the metropolis of Sydney. He determined the admission rate for rheumatic valvular disease to seven hospitals for ten years and compared this with similar public hospitals from other countries. The percentage of total hospital admissions appeared to vary between 0.27 and 0.39 for adult hospitals to 0.7 for a large children's hospital. Rheumatic valvular lesions formed 0.47 per cent of the total admissions. Postmortem evidence of rheumatic valve injury, observed at the Royal Prince Albert Hospital for a similar period, was found in 1.5 per cent of the total necropsies. In Adelaide a rate of 3.8 per cent has been recorded. The survey results in the general conclusion that New South Wales is fortunate in occupying an intermediate position with regard to the incidence of cardiac rheumatism, since the general figure for the whole population of New South Wales, from 0.3 to 0.6 per cent, falls far short of the prevalence in the Old World or northern United States but is considerably more than is found in the tropics. The general incidence of rheumatism for all rural areas examined was 2.7 per cent; of organic heart disease of rheumatic character, 0.6 per cent. Rheumatism is distributed fairly evenly over New South Wales, while rheumatic heart disease is found more on the tablelands and slopes than in the coastal regions. In the coastal mountain range (Blue Mountains) and the areas close to its inland slopes there is a higher incidence of organic cardiac rheumatism. Certain coastal areas characterized by salt water lagoons are severely affected. In dusty areas with low annual rainfall of high seasonal concentration, and with high summer temperatures the incidence is low. Urbanization in New South Wales, at least with one possible exception (Lithgow), does not appear to raise the incidence of cardiac rheumatism. No increase is found in areas under close artificial irrigation and of high damp ground. Similarly, flat coastal areas abundantly intersected by rivers and with a high rainfall are usually free of cardiac rheumatism. As rheumatic fever is not a notifiable disease, it is impossible to make an exact estimate of its distribution within the city of Sydney. The common experience of all observers has been that it is almost entirely a disease of the public hospital class of citizen from the poorer industrial quarters. The records of the larger general hospitals of Sydney show that the slum areas and others most heavily populated by members of the public hospital community provide most of the cases. The slums, however, in no sense approach the character of those in the poorest parts of the larger European cities. The total number of patients plotted in this way amounted to 800. No definite relationship to known damp areas, either damp ground or poorly drained areas, could be established.

*Submucous Lipomas of the Stomach. M. Bariety and G. Brouet.—p. 209.

Submucous Lipomas of the Stomach.—Bariety and Brouet draw attention to lipomatous tumors of the gastro-intestinal tract ranging from 3 or 4 mm. to 6 cm. in diameter. They sometimes occur in clusters or are dispersed. They may be oval and pedunculated, disklike or pear shaped. The authors mention a case of intestinal lipoma which was traumatized by a foreign body with resulting ulceration. It may also happen that its internal or adjacent blood supply becomes interfered with, resulting in edema, congestion, ulceration, hemorrhage, leukocytic infiltration and necrosis. Ulcerations are generally small, mostly the size of a lentil. Of all the gastric tumors lipomas are rarest, occurring more frequently in men than in women and mostly beyond the age of 40. Lipomas may remain without symptoms unless they are complicated by muscular disorders, ulcerations or pyloric obstruction. In these cases there is slight pain intensity and a feeling of emptiness in the stomach, of heaviness or of painful cramps as in ulcer; in most instances they resist all therapeutic efforts. The authors observed the absence of free hydrochloric acid after a test meal. Roentgenologically they are mostly confused with other benign tumors, perhaps because of their small size. A certain degree of pyloric stenosis and gastric residue may lead to the diagnosis, which will have to be differentiated from true pyloric stenosis, cancer, ulcer or simple dyspepsia. A serologic examination will eliminate syphilitic gumma. In the face of the difficulties of arriving at a diagnosis the treatment cannot be but symptomatic, except for stenosis and hemorrhage. In these the changes of the gastric mucosa may become pronounced and frequent hemorrhage will necessitate a surgical intervention. Technical difficulties will arise in diffuse lipomatosis and when multiple exereses must be performed.

Severe Hepatonephritis in Myasthenia. N. C. Vasilescu.—p. 378.

Blood Density in Tuberculosis.—Ravinia and his associates have examined the blood of forty tuberculous and twenty persons with other disorders following a few days of rest. They mix equal parts of blood taken from a fasting patient and distilled water in a small flask and place it in an incubator for a few seconds. It is then weighed. The authors have thus determined that the blood density in tuberculous patients is decidedly lower than that of others (1.046 to 1.05). At the same time they have established the fact that the heart of patients with pulmonary tuberculosis shows smaller dimensions. This may be explained by secondary changes like adhesions which are, as the case may be, capable of increasing or diminishing the dimensions of the heart. Added to this is also a lower arterial blood pressure in tuberculous patients. As a corollary they also found that the blood density in women is slightly lower than that of men, and that hypertension goes mostly with relatively heavier blood.

A New Spirochetosis.—Lesné and his associates observe that the domain of the spirochetes is increasing every year. In a patient, aged 13, with fever oscillating between 100 and 102 F. and lasting for three weeks, the authors isolated spirochetes, from 2 to 3 microns long, presenting from 2 to 10 spirals and a thickness of from 0.25 to 0.4 micron. They have great mobility and are easily stained by methylene blue, gentian violet and fuchsin. They thrive best in 4 parts of Martin's bouillon with 1 part of blood. A monkey tested with this culture responds in about four days with a thermic reaction of 104 F., lasting for two days without visceral symptoms. The spirochete is a pathogenic saprophyte showing distinct charac-

teristics of culture and virulence similar to the spirochetes described by Pons (*Spirochaeta sinensis*) in 1923 but different only in time of recovery.

Tomography in Diagnosis of Pulmonary Lesions: Medico-surgical Interest in This Method. E. Bernard.—p. 446.

Pure Bone in Pegging Diaphysial Fractures.—Neuman maintains that metallic osteosynthesis has still many postoperative complications in spite of all technical improvements. He gives the history of six diaphysial fractures of long bones with overriding fragments. Under general anesthesia the two fragments are freed from interposed soft tissues and a piece of beef bone, 8 cm. long and 1 cm. wide, from which all fat and albumin have been removed, is inserted in the medullary cavity of the inferior fragment. The upper fragment is then manipulated so as to slip over the protruding part of the peg. This operation can be done in a few minutes without any difficulty. The wound is closed without drainage and a cast is applied. Among the six patients was a boy, aged 5, with a fracture of the lower radius and ulna successfully treated by pegging. In all cases exact coaptation and quick callus formation was achieved. The peg is gradually absorbed.

*Teleröntgen Therapy of Cancer. P. Cottenot and E. Chérigé.—p. 262.

Teleröntgen Therapy of Cancer.—In the treatment of deep-seated cancers with possible metastases, Cottenot and Chérigé utilized a greater focus-skin distance, higher voltage and more filtration, realizing a more equal distribution of rays over the surface of the fields. By increasing the kilovoltage to 200 they reached a greater depth, but the gain became negligible beyond 200 kilovolts. One mm. of copper improves the ratio of penetration about 13 per cent as compared with corresponding thicknesses of aluminum. The increase from 1 mm. of copper to 2 mm. is much less practical. Increasing the focus-skin distance from 1 meter to 2 meters affords about 6 per cent increase in the ratio of depth penetration given the same filtration. With increased distances, the intensity of the rays is the same in the middle as at the periphery of the field. It is thus possible to administer from 2,000 to 3,000 roentgens per field, utilizing from four to six fields and giving from 250 to 450 roentgens weekly. For fields 35 cm. in diameter a focus-skin distance of 70 cm. (semiteleröntgen therapy) is enough to destroy the cancer cells, while the defense elements of the body are imposed on as little as possible. Much different is the teleröntgen therapy applied by Mallet. His fields are from 40 to 50 cm. in diameter, so that two of them suffice to irradiate the body. His tension is from 180 to 300 kilovolts and filtration from 0.5 to 1 mm. of copper, giving not more than from 1,000 to 1,200 roentgens per field and necessitating about sixty or eighty treatments. But this method, although it gives a more homogeneous irradiation, has an injurious influence on the hematopoietic organs, because of its extended action. While it sterilizes the young cancer cells, it leaves the older cells almost intact. The semiteleröntgen therapy, as practiced by the authors, has given good results in bony metastases and cancers of the breast and uterus, but the results on the esophagus were less favorable.

Combined Action of Carbonic Acid Baths and Oxygen Inhalation During Voluntary Apnea. R. Marchal.—p. 471.
Allogenic Vasculotissular Reactions. L. Alquier.—p. 473.

Action of Carbonic Acid Baths.—A carbonic acid bath when taken at a temperature of 91.5 F. lowers the systolic and diastolic blood pressure during the first few minutes and later

raises it. It brings about a dilatation of skin capillaries, retards the pulse and increases the diuresis. André investigated its action on general metabolism and peripheral circulation. He had seven subjects between the ages of 24 and 47 years on whom he conducted his experiments, choosing about four hours after the last meal as the suitable time. He observed that the volume of expired air was increased 23 per cent. If the respiratory quotient was 0.88 before the bath, it rose to 1.16 during the bath. The average metabolic rate was increased 9.5 per cent during the bath. Briefly, a carbonic acid bath at 91.5 F. accelerates the peripheral circulation through absorption of carbon dioxide through the skin and its elimination by expiration. A bath of tap water of the same temperature tends mostly to slow down circulation. The p_{50} drops from an average of 7.41 to an average of 7.38 and this is usually accompanied by a surplus of carbon dioxide in the blood (from 50.89 to 53.36 per cent). In spite of this drop of p_{50} the average rate of oxyhemoglobin is raised from 82.5 to 86 per cent. The main argument against these figures would be the possible inhalation of carbon dioxide given off by the bath. But the author provided his subjects with pure air from without by hyperventilation and the figures obtained were the same. It is essentially the anhydride of the carbonified water, which, penetrating the immersed skin, increases the carbon dioxide contents of the venous blood.

Tumors of Retroperitoneal Space.—In 1929 Hesse described a triad of symptoms of retroperitoneal tumors and their influence on the sympathetic nerves of the corresponding lower limb. These symptoms are lowering of the temperature, excessive sweating and, during the period of nervous excitation, exaggerated pilomotor reflex in the lower limb which corresponds to the side of the tumor. During the period of advanced destruction, when the sympathetic nerve is either inhibited or paralyzed, the temperature of the limb is again increased, the sweating stops and the pilomotor reflexes are arrested. These symptoms are important when the tumor is in its early stage during which the diagnosis and the localization of the growth can be made with no other methods. The difference in temperature is best measured at the toes or at the back of the foot. By merely laying the hand on both feet, the difference in temperature can often easily be made out. For more minute comparisons, comparative thermometry will have to be applied. By means of this method it is possible to tell whether the process is in its initial or its advanced stage. The temperatures of both limbs are traced daily and the day on which the two temperatures are the same indicates the passage from the state of nervous excitation to that of inhibition or paralysis. The author named this crossing "calorimetric scissors." These symptoms are verified on eight patients, in some of whom the difference of temperature was often more than 5 degrees and well noticeable to themselves.

Differential Diagnosis of Adnexitis and Tubal Abortion.—Geyer advises the use of the hemostatic test of congo red for the differential diagnosis of adnexitis and tubal abortion causing metrorrhagia. The test consists in the administration of an intravenous injection of 10 cc. of a 1 per cent congo red solution each day for three consecutive days. If metrorrhagia is caused by adnexitis, it stops immediately after administration of the congo red injections. If it is caused by tubal abortion, the treatment fails. The treatment is harmless and can be given to ambulant patients. Four cases are reported.

- *Natural Antistaphylococcic Immunity in New-Born Infants and in Children. G. C. Bentivoglio and S. Moschini.—p. 153.
- Infectious Adenopathic Monolymphocytosis: Cases. F. Cantarutti.—p. 184.
- Hemiplegia in Heart Disease: Case. Leonida Zilotti.—p. 190.

Natural Antistaphylococcic Immunity.—Bentivoglio and Moschini state that a degree of natural antistaphylococcic immunity may exist in infants and in children of different ages. Immunity in these cases is proved by the presence in the blood serum of staphylococcic antitoxin, which can be determined by the hemolytic method. The amount of staphylococcic antitoxin in the blood serum of new-born infants is the same as that in the blood serum of their mothers. Passive immunity of maternal origin diminishes rapidly after birth and in two or three months the staphylococcic antitoxin almost disappears from the blood. It again increases, however, after this time up to the age of 7. The amount of staphylococcic antitoxin in the blood serum of children from 7 years of age on is the same as that in the blood serum of adults; that is, about 1 unit of antitoxin for each cubic centimeter of blood serum. The amount of staphylococcic antitoxins in the blood serum of children is greater in the course of staphylococcic diseases, or shortly after their occurrence, than during the course or after the occurrence of diseases other than staphylococcic. Natural antistaphylococcic immunity is due to previous contagions or infections, which evolved according to several individual and other factors that were prevailing at the time the infection took place, so that a diagnosis as to the origin of the infection is not made at that time. The quantitative behavior of staphylococcic antitoxin in the blood serum shows an important phase of the clinical problem of natural antistaphylococcic immunity.

Pathologica, Genoa

- Behavior of Brain in Experimental Catatonia in Dogs. E. Mondio and F. Pino.—p. 148.
- Amyloid Degeneration and Splenectomy: Experiments. G. S. Niosi.—p. 155.

Creatinemia Following Ligation of Splenic Artery.—De Vitoris-Medori made determinations of the creatine bodies in the blood of rabbits following ligation of the splenic artery. He found a temporary lowering of the total creatinemia, which returns to normal figures in about thirty days after the operation. According to the author the hypocreatinemia is relative. It is due to diminished concentration of creatine bodies in the blood subsequent to the production of hydremia, which follows ligation of the artery, with consequent rupture of the ratio between the liquid and solid parts of the blood. The statement is proved by the fact that ligation of the splenic artery is followed by a temporary diminution of the index of refraction

of the blood which parallels that of the creatine bodies. A direct influence of the spleen on the creatine bodies does not seem to exist, according to the results of the author's experiments.

Plurality of Leishmania Donovan.—Sangiorgi found a great variety in the morphology of *Leishmania donovani* during bacteriologic studies of splenic material in a case of kala-azar in an adult. He wonders whether there are several strains of *Leishmania donovani* and, in this case, whether the different morphology of several strains is related to the virulence of the strain and to its selectivity for adults or children. In this connection, he advises the cultural and biologic studies of *Leishmania donovani*. The author's study does not include *Leishmania infantum*, which etiologically is not identical with *Leishmania donovani*.

- *Determinations of Chlorides in Blood Plasma and Globules in Prognosis and Treatment of Acute Intestinal Toxi-Infectious Syndrome in Infants. F. Hurtado Galtés.—p. 92.
- Parrot Disease in Infant: Case. J. Pedrera.—p. 104.

Chlorides in Blood in Acute Intestinal Toxicosis.—Hurtado Galtés advises repeated determinations of the chlorides in the blood plasma and globules and of the alkali reserve, early in the course of acute intestinal toxicosis in infants. The normal chloride globuloplasmatic coefficient is 0.5 and corresponds to 0.5 volume in the Van Slyke scale for the alkali reserve. Higher and lower figures than that of 0.47 for the globuloplasmatic coefficient show, respectively, hyperchloremia (acidosis) or hypochloremia (alkalosis). Early treatment is of importance. Infants suffering from hyperchloremia are given intramuscular injections of a 2 per cent sodium bicarbonate solution, or intravenous injections of a 4 per cent solution of the same substance. The treatment is associated with the administration of an isotonic solution of dextrose if the increase of the coefficient is due to increase of the chlorides in the globules over those in the plasma. It is associated with the administration of Ringer's solution if the chlorides in the plasma are greatly diminished. When the increase of chlorides in the globules and the plasma is parallel, salt solutions are not resorted to. The patient is given liberal amounts of dextrose solution for rehydration and insulin (no more than 2 units of insulin for each 4 Gm. of dextrose). Infants suffering from hypochloremia are given liberal amounts of Ringer's solution and hypertonic solution of sodium chloride. By administering the treatment according to proper indications, the development of the almost fatal syndrome that complicates alkalosis erroneously treated by alkali is prevented. A drop by drop intravenous instillation is the best method for administering solutions of dextrose or sodium chloride. Direct transfusion is also of value.

Free Gas in Peritoneal Cavity.—According to Petrén, roentgenologic examinations for the last five years at the Surgical Clinic of Lund of patients presenting symptoms of acute abdominal disease demonstrated the presence of free air in the peritoneal cavity in about two thirds of the cases of perforation of gastric or duodenal ulcer. Free gas can be demonstrated as early as five hours after the perforation. This roentgenologic sign was also present in a number of cases of perforation of gastric and colonic cancer and of perforations of the small intestine. The failure to obtain the sign does not rule out the existence of the perforated ulcer, since in one third of the cases the sign was absent. The diagnosis of the perforated ulcer in the cases in which the roentgenologic sign was positive presented no diagnostic difficulty and could have been arrived at

without resorting to roentgenologic examination. The author does not recommend routine employment of the method in cases of acute abdominal disturbance in which perforation is not suspected. The roentgenologic examination for free gas in the peritoneal cavity can be made with the patient lying down in the left lateral position. Of forty cases of perforation of ulcer examined roentgenologically for the presence of free air, twenty-seven were positive and thirteen were negative. The roentgenologic examination was of determining diagnostic value in only six. In a group of forty-two cases of perforation of ulcer in which no roentgenologic examination was made, the diagnosis presented no difficulty. The demonstration of free gas in the peritoneal cavity was thus of diagnostic value in six out of eighty-two cases. The author feels that the practical value of the method should not be overestimated. In about 10 per cent of the cases of perforation of ulcer the diagnosis may present difficulties, and it is in these that the roentgenologic demonstration of free gas in the peritoneal cavity is of determining value.

Does Radioactivity of Ground and Air Have Climatotherapeutic Significance? H. Israel-Köhler.—p. 632.

Effects of Change of Weather on the Human Organism.—Everyday experiences show that noticeable reactions of the human organism take place only in case of weather changes. Kühnau says that the manner in which weather changes influence the organism is extremely complicated. A part of the effects of weather changes on the organism—drastic changes of the air moisture, temperature and wind velocity—can be explained by a sudden demand on the temperature regulation of the organism. In "weather sensitive" subjects, however, weather changes become noticeable also outside the temperature regulation, for instance in sudden metabolic changes. Sensitive persons may even feel changes in the weather in advance. These phenomena have not been completely explained as yet. Individual persons react to stimuli of meteorological changes in different ways and with different intensities. Some of the influences on the human organism can be explained by a modification of the sympathetic nervous system. Children and persons of the leptosome type are frequently irritable and restless during the passage of an arctic front but drowsy and somnolent during the passage of an equatorial front. The author cites Petersen's opinions about the effects on the organism of the invasion of the arctic front (anticyclone) and of the equatorial front (cyclone) and discusses the influence exerted by changes in air bodies on the blood pressure, the basal metabolism and the morphology and chemistry of the blood. The author thinks that there is a tendency to underestimate the influence exerted by the meteorological conditions on the healthy individual and that a better knowledge of the physiologic actions of the weather will aid in the understanding of its rôle in the development of diseases.

Mites as Endoparasites in Urinary Passages.—Pfaffenberg and Konischewski point out that the theory of true endoparasitism in the gastro-intestinal tract seems to be contradicted

by the fact that it has never been possible to demonstrate living mites in the feces. To be sure, the feces of dogs that had been experimentally infected with mites have been found to contain living mites, but even the occasional appearance of living mites in the stools would not necessarily indicate parasitic action. Whereas a mite-endoparasitism of the intestinal tract has not been definitely proved, there seems to be evidence of mite-endoparasitism in the urinary tract. After reviewing the literature on the occurrence of mites in the urinary tract, the authors report two cases of their own observation. One concerned a baker, aged 26, who complained of pains in the hypogastric region and in the kidney of the right side. The patient had a nephritis that was complicated by a paranephritic abscess. Mites of the type *Tyroglyphus* were detected in urine that had been withdrawn under sterile conditions from the bladder and the ureter. The second patient was the wife of the first patient. She too had living mites of the same type in the urine that had been withdrawn from the bladder and the ureters as well as in the urine that was voided spontaneously, but she had no symptoms of disease. In order to determine whether perhaps bakers are especially exposed to mite-endoparasitism of the urinary tract, studies were made on 119 bakers. The tests that were made under absolutely sterile conditions always were negative. From this it is concluded that the occupation of the first patient was of no significance for the infestation with mites.

Orthopedic Treatment of Permanent Injuries of Upper Extremities. F. Kirschner.—p. 430.

Treatment of Pseudarthroses.—Martin tried to differentiate between retarded healing of a fracture and pseudarthrosis, for he considered this differentiation important for the treatment. He thinks that, if the callus at the end of the fracture is still cloudy, without sharp outlines and without structure, the callus formation is still in progress and that cloudy, more or less connected shadows indicate the same, provided continuous roentgenologic control examinations have not already revealed retrogressive processes. He emphasizes that the healing of fractures differs greatly as regards duration as well as manner and extension of callus formation. This is proved by continuous roentgen controls. Considerably retarded callus formation justifies Beck's drilling of the bone. This method is simple and highly effective. He admits that in the healing of a fracture all parts of the bone play a part: the marrow, the corticalis and the periosteum, but he regards the marrow as of primary importance and shows that the great value of Beck's drilling lies in the fact that it establishes a connection between both marrow cavities. He emphasizes the value of continuous observation of a healing bone fracture. He tells of a patient with pseudoarthrosis who has been under his observation for twenty years. In numerous roentgenograms he was able to observe the development and cure of the first pseudoarthrosis, a relapse and its cure, and finally the regeneration of the bone defect at the site from which the transplantation had been taken.

*Irradiation in Lymphogranuloma. W. Baensch.—p. 464.
Orthopedic Treatment of Permanent Impairments of Upper Extremities. F. Kirschner.—p. 466.

Irradiation in Lymphogranuloma.—Baensch, in discussing the ray treatment of lymphogranuloma, admits that this method is not a causal one and can influence only the secondary manifestations. His experiences with ray treatment are based on seventy-eight cases in which the treatment has been completed and on ten in which treatments are still being given.

Roentgen or radium treatment is resorted to again and again, because the medicinal treatment fails to produce satisfactory results. Some authors recommend small and others massive doses. On the basis of his own observations, he advises small doses to begin with, for the smaller the initial doses, the longer will the irradiation remain effective. Moreover, it is characteristic for lymphogranuloma that it reacts promptly to small doses. After giving the first focal dose of 150 roentgens, the author tries to secure for the patient climatic or heliotherapy, as he saw favorable effects from heliotherapy, particularly during the first and second stages of lymphogranuloma. To be sure, if lymphogranuloma takes a fulminant course, heliotherapy is ineffective, for these cases usually terminate fatally within a few months. Frequently, however, heliotherapy is followed by a latent stage, which may last from several months to three years. After that the glandular swellings recur either in the same regions or in adjoining ones. During the second stage it is generally advisable to administer about 300 roentgens to each field. The author observed in many cases that the glandular swellings as well as the fever subsided between the fourth and sixth days after the irradiation. For this reason he did not irradiate the same region after shorter intervals but waited at least six or eight days. Occasionally considerable improvement is still obtained during the second stage, but the glandular swellings are usually refractory to the influence of rays during the third stage. In case of superficial glandular swellings, radium treatment accomplishes about the same as does roentgenotherapy, but if deeper lying lymph nodes are involved, particularly the mediastinal and bronchial ones, roentgen irradiation is usually preferable.

- Course of Delivery in Old Primiparas. H. Döring.—p. 322.

Percutaneous Puncture of Hydramnion During Pregnancy.—Mayer directs attention to the fact that a severe hydramnion may cause considerable difficulties, such as severe dyspnea. If the signs of congestion become too severe, evacuation of the over large uterus by artificial termination of the pregnancy may become necessary, but the author suggests puncture of the hydramnion through the abdominal walls as another possibility. He thinks that the measure is indicated in serious signs of congestion with dyspnea. The technic is comparatively simple. The skin is disinfected and the puncture is made with a sterile trocar. The author usually makes the puncture about midway between the symphysis and the umbilicus, in the midline, because here are the fewest vessels and normally there are no intestinal loops in this region, so that the danger of damaging the intestine is excluded. In order to avoid injuries of the urinary bladder the puncture is preceded by catheterization. Local anesthesia is used. The amount of amniotic fluid withdrawn varies between 850 and 3,750 cc. The immediate result of the puncture was always good. The further course of the pregnancy varied. In order to avoid labor pains, morphine or some other opium preparation was administered. Mild labor pain appeared in two cases but subsided again. In five cases delivery took place after one, three, six, eight and ten days, respectively, but in the other cases up to ten weeks elapsed before the termination of the pregnancy. The author never observed damage to the child.

Simultaneous Intra-Uterine and Extra-Uterine Pregnancy.—Neumann reports the clinical histories of three cases of simultaneous intra-uterine and extra-uterine pregnancy. In the first woman intra-uterine pregnancy concurred with a tubal pregnancy. The second patient had an intra-uterine and an ovarian pregnancy. In the third woman pregnancy existed simultaneously in the main horn of a uterus unicornis and in the atretic accessory horn.

Borderline Rays in Treatment of Lupus.—Bamberg and Kröker report their observations on several hundred patients with lupus. After discussing the reaction of the tissue to the borderline rays, they point out that failure of this treatment is frequently caused by a faulty technic. They work with 9 and 10 kilovolts and 10 milliamperes. The half layer value amounts to from 0.0185 to 0.02 mm. of aluminum. The focus skin distance is between 2.5 and 5 cm. In order to be able to apply the large doses of rays required for the strong skin reaction without impairing the curative action, efforts were made to combine the borderline ray therapy with other methods; namely, with a preliminary irradiation with red rays and with the application of a tuberculin ointment. The combination therapy is employed in the following manner: After the crusts and scabs have been removed from the lupus focus, a small amount of tuberculin ointment is rubbed in. Then red rays are applied for fifteen minutes and this is followed by treatment with borderline rays. Whereas formerly the initial dose of borderline rays had to be from 2,000 to 2,500 roentgens, the combination treatment makes it possible to reduce it to from 1,000 to 1,500 roentgens. This dose is also generally adhered to for the later irradiations; occasionally it is increased to 2,000 roentgens. Several weeks elapse before the first reaction subsides. After that, the second irradiation is given. A therapeutic cycle, that is, the treatment required for a temporary cure of a lupus focus, consists of from 15,000 to 20,000 roentgens. The described combination therapy of lupus prevents the application of large doses of rays and with that, ray injuries. The method is an inexpensive and ambulatory treatment.

- Clinical Aspects and Therapy of Early Tuberculous Infiltrate. W. Neumann.—p. 411.

Technic of Vaccination.—Kaiser points out that, although vaccination has been practiced for more than a century, it still involves dangers. A review of the cases in which complications developed showed that the largest number were the result of the epidermal growth of the pustule. The superficial position of the infectious pus under the thin cover of epidermis is dangerous. Thus it is that efforts have been made to effect an immunization against smallpox without epidermal efflorescence. Studies have been made to determine whether immunity can be produced by other than the cutaneous method. The author reviews experiments with the intracutaneous administration of the vaccine that were conducted by other investigators and then describes his own observations with subcutaneous vaccinations. The mothers of the children prefer this method. In a few cases complications have developed in the form of polymorph exanthem and of vaccinia generalisata. The immunity is still good after a year but cannot yet be estimated for a longer period. Moreover, the favorable effects that have been accomplished in the past with the customary cutaneous method should not be overlooked.

Sedimentation Speed in Cerebral Disorders.—Singer and Edel studied the blood sedimentation speed of 115 patients with cerebral disorders. Their conclusions are based only on cases that were verified by operation or definite clinical manifesta-

tions. They found that the determination of the sedimentation speed of the erythrocytes is valuable, especially from the neuro-surgical point of view. The sedimentation reaction permits a differentiation (1) between hydrocephalus with a normal sedimentation speed and cerebral tumor with slightly accelerated sedimentation speed, (2) between serous meningitis (with normal sedimentation speed) and cerebral tumor, (3) between acute encephalitis, in which the sedimentation speed is greatly increased, and cerebral tumor, and (4) between hemorrhagic pachymeningitis (with moderately increased sedimentation speed) and cerebral tumor. The sedimentation speed is helpful also in determining the benign or malignant character of a cerebral tumor. Meningioma and glioma are characterized by a moderately accelerated sedimentation speed and can thereby be differentiated from carcinomatous metastasis, in which the sedimentation speed is greatly accelerated. If the problem is to distinguish between cerebral arteriosclerosis and cerebral tumor, a greatly accelerated sedimentation speed is indicative of cerebral arteriosclerosis, whereas a normal or slightly accelerated sedimentation permits no differentiation in such cases. The authors do not consider these studies completed but are continuing their investigations.

*Diagnostic Significance of Condition of Cerebrospinal Fluid in Encephalitis, Poliomyelitis and Infectious Serous Meningitis. K. Hassmann.—p. 384.

The Cerebrospinal Fluid in Certain Diseases.—Hassmann points out that there are three groups of disorders of the central nervous system which are of especial significance as regards the condition of the cerebrospinal fluid: infectious encephalitis, infectious poliomyelitis and infectious serous meningitis. Nearly all disorders belonging to these groups show similarities not only as regards the clinical symptoms but also as regards the reactions of the cerebrospinal fluid. The examination of the cerebrospinal fluid in a large number of cases with these disorders revealed that it is incorrect to say that the sugar content of the cerebrospinal fluid is always normal or increased in the aforementioned disorders. In all three of these groups he observed numerous cases in which the sugar content of the cerebrospinal fluid was noticeably decreased. He was unable to detect a relationship between cell number, type of cell and the sugar content. Repeated examination of the cerebrospinal fluid in the same patient seemed to indicate that, as regards the sugar content and the cells of the cerebrospinal fluid, individual factors play an important part.

Therapeutic Value of Chemical Group Containing P-Aminobenzenesulfonamide: I. (Frontosil). T. Kucharski.—p. 338.

Abscess of the Prostate.—Drucker operated early in twenty-eight cases with one death due to septicemia. Prognosis of abscess of the prostate when diagnosed correctly and operated on immediately is most always good. One patient had perinephritis but recovered after early operation. Early incision of the abscess has for its object the prevention of recurrence, of rupture into the other organs and of general infection. In hematogenous abscess the prognosis is not so good, especially in neglected cases. Abscess of gonorrheal origin must be opened early, as conservative treatment often leaves a focus of latent infection which, after years of apparent cure, may become active.

Epidemiologic Characteristics of the Grip Epidemic of 1936. I. A. Dobreytser.—p. 441.

Epidemic Grip.—Smorodintsev and his associates, in the course of the grip epidemic in 1936, established the fact of quantitative increase in the number of pneumococci, Pfeifer bacillus, *Micrococcus catarrhalis* and, in a number of cases, of *Streptococcus haemolyticus* in the throats of the patients. The greatest increase corresponded to the first five or six days. The authors suppose that the primary cause of epidemic grip is a filtrable virus which produces an inflammatory process in the respiratory tract and that the virus activates such microbes as the pneumococcus or the Pfeifer bacillus. Active immunity in mice was increased by subcutaneous injection of nonfatal doses of the virus. The immunity lasted seventy-five days. With the inhalation method of immunization it was extended to 150 days. The virus introduced by the inhalation method is rapidly destroyed and, two days later, the animal is capable of surviving the introduction of 1,000 fatal doses. The authors conclude that the loss of infectivity in an actively immunized animal is due to increased capacity of the tissues, and in particular of the pulmonary tissue, to destroy the virus. Eighty volunteers were infected with increasing doses of the mouse virus, utilizing the inhalation method. The maximal amount introduced was from 0.5 to 1 cc. of a 10 per cent emulsion of lung tissue of white mice, which were infected with a fatal dose of the virus and killed two days later. About one fifth of the volunteers became infected and presented a mild form of the grip, resembling in its main features the epidemic variety. The authors found that quantitative and qualitative analysis in experimental grip showed no increase in the number of pneumococci, *Streptococcus haemolyticus*, bacillus of Pfeifer or *Micrococcus catarrhalis*. There was no increase in the amount of the virus present in the respiratory passages. None was present forty-eight hours after the infection. The loss of virulence of the mouse virus introduced into man was also demonstrated by the absence of contagiousness on the part of the medical personnel treating the infected patients. The authors were able to demonstrate that the development of experimental grip depended on the content of the antiviral immune bodies in the blood. This content increased through the method of introduction by inhalation, suggesting prophylactic possibilities against epidemic grip.

*Investigations on Relation Between Bleeding Time and Number of Blood Platelets in Essential Thrombopenia (Werlhof's Disease) After Injection of Epinephrine. A. B. Hansen.—p. 368.

Bleeding Time in Essential Thrombopenia.—Hansen found a marked rise in the thrombocyte count in two cases of essential thrombopenia after injection of epinephrine, in one case maintained during twenty-three days' observation, in the other continuing for a few days. In two splenectomized patients with essential thrombopenia, injection of epinephrine failed to increase the number of thrombocytes. The marked increase in thrombocytes in the peripheral blood after the injection of epinephrine in the first cases is believed to depend on a release of thrombocytes from the various depots in the organism, primarily the reticulo-endothelial system. The author asserts that there is no direct relation between the thrombocyte count in essential thrombopenia on the one hand and the time of bleeding according to Duke and the origin of spontaneous hemorrhages in the skin and mucous membranes on the other. The abnormal duration of bleeding in cases with normal blood platelet values may be due to an agglutination defect in the platelets, and spontaneous hemorrhages in cases with normal platelet count must be explained either by a defective production of thrombokinase or by abnormality of blood vessels.

RHEUMATOID ARTHRITIS

A COMPARATIVE EVALUATION OF THE COMMONLY
EMPLOYED DIAGNOSTIC TESTS

CHARLES L. SHORT, M.D.

LOUIS DIENES, M.D.

AND

WALTER BAUER, M.D.

BOSTON

In order to follow the course and evaluate therapy in a chronic disease, the need is evident of an objective laboratory test to supplement clinical observation. Diagnostic tests, such as the Wassermann reaction and its modifications, are at hand in the case of syphilis. The basal metabolism is employed as a diagnostic test as well as a therapeutic "measuring stick" of one of the important abnormalities in thyroid disease. The lack of a diagnostic test and a therapeutic "measuring stick" in a chronic disease of unknown etiology characterized by remissions and relapses, such as rheumatoid arthritis,¹ is all too apparent to the student of this disease. Certain "measuring sticks" have been applied from time to time and correlation attempted with the course of the disease. Among the more important in use thus far are the sedimentation rate of the red blood corpuscles, the determination of the number of younger polymorphonuclear leukocytes in the peripheral blood (Arneth-Schilling count and modifications), the Vernes resorcinol test, and the power of the blood serum to agglutinate certain types of streptococci. It is our purpose in this paper to evaluate the accuracy of these four tests in a group of undoubted cases of clinically active rheumatoid arthritis, with simultaneous performance of all four tests in most instances.

In 1703, long before the advent of clinical laboratory methods, the "buffy clot," which from the work of Fahraeus² we now know represented the increased sedimentation rate of the red blood corpuscles, was observed in rheumatism by Musgrave.³ Over 200 years later, in 1924, the first extensive investigation of the sedimentation rate in acute and chronic arthritis was made, by Herrmann.⁴ His conclusions have been largely confirmed

by all subsequent workers. In brief, the rate was increased in rheumatic fever, gonorrheal arthritis, acute gouty arthritis and rheumatoid arthritis but normal or nearly so in degenerative arthritis⁵ and nonarticular rheumatism (myositis, fibrositis, sciatica, lumbago). In rheumatoid arthritis, he found that the rate roughly paralleled the grade and intensity of the disease, was low in burned out cases, was of aid in determining the proper time for joint operations, and was sometimes valuable in diagnosis when few objective signs were present. Herrmann's work was confirmed in the next few years by Kahlmeter,⁶ Race⁷ and Dittges,⁸ while the first report of Dawson, Sia and Boots,⁹ in 1930, has resulted in the acceptance of the test by many workers¹⁰ in this country as a valuable aid in the management of cases of arthritis.

The sedimentation rate of the red blood corpuscles is, of course, entirely a nonspecific reaction. It is increased in most infectious diseases, as well as in malignant growths, hepatic jaundice, pregnancy and other noninfectious conditions with tissue destruction. The exact mechanism of its action is not known as yet. Cross experiments have shown that it is a function of the plasma and not of the cells. Increased rates may be related to the changes in the plasma proteins, which have been observed in arthritis and other diseases. Interesting recent work¹¹ has shown that in rheumatoid arthritis there is a tendency toward a reversal of the normal albumin-globulin ratio, while the fibrinogen is usually increased. Further studies along these lines might aid in elucidating the pathologic physiology concerned.

While there may be a leukocytosis during the acute febrile stage, which often ushers in an atypical attack of rheumatoid arthritis, as a rule the well established case shows a normal or even low white blood count.

5. Synonyms for degenerative arthritis are hypertrophic arthritis and osteo-arthritis.

Similarly, a polymorphonucleosis may be present in the early stages, leading later even to a neutropenia with an increase in the number of the lymphocytes. Thus both the white blood cell count and the routine (Ehrlich) differential leukocyte counts are of little assistance in following the course of the disease. On the other hand, the presence of young polymorphonuclear leukocytes in the peripheral blood has been quite constantly observed in rheumatoid arthritis since the work of Dittes⁸ in 1929, and in consequence Schilling, or filament-nonfilament leukocyte, counts have been utilized in recent years by various British and American workers.¹²

* Meaning that any one of four streptococcus agglutination reactions was positive.

While no final conclusions can yet be drawn, this test is usually positive in cases of clinically active rheumatoid arthritis. Again, we are dealing with a nonspecific test, representing a bone marrow response, found in many infectious and noninfectious conditions.

The Vernes resorcinol test is relatively unfamiliar in this country but has been quite extensively used in France in charting the activity of various diseases. In the United States, its use in tuberculosis was suggested in 1927 by Baylis,¹³ who in the following year published the description of a simplified method.¹⁴ Briefly, this consisted in mixing 0.5 cc. of a 1.25 per cent aqueous solution of resorcinol with an equal quantity of the patient's serum and allowing the mixture to stand over night in the refrigerator. The degree of turbidity observed supposedly represents an approximation of the clinical activity of the disease. In 1931 Coste, Lacapère and Rapaport¹⁵ applied the Vernes test to the study of arthritis. Other French authors¹⁶ agree that the test is of real value, with most cases of rheumatoid arthritis showing abnormal readings. Again the test is entirely nonspecific, since it is positive in tuberculosis, syphilis and other infections as well as in malignant conditions. The mechanism of the reaction is unknown. It is probably related to the precipitability of plasma proteins by electrolytes, with fibrinogen eliminated, since serum, not plasma, is used.

In 1930 Cecil, Nicholls and Stainsby¹⁷ reported that hemolytic streptococci recovered from the blood and synovial fluid of patients with rheumatoid arthritis were uniformly agglutinated to a high titer in the serums obtained from patients with rheumatoid arthritis. Further work disclosed that hemolytic streptococci obtained from patients with other infectious diseases would give similar reactions. Nearly all normal and pathologic control serums were negative and other organisms failed to be agglutinated in arthritic serums. Dawson, Olmstead and Boots¹⁸ (along with other American workers¹⁹) have confirmed these observations and have disclosed in addition that the R pneumococcus will give similar positive results. The agglutination reaction is usually negative in children or in the first six months of the disease in adults, increases in intensity as the disease develops, and may disappear with recovery. In Cecil's original paper, the test was compared to the Widal reaction in typhoid, as specific and reliable in the diagnosis of rheumatoid arthritis. Later studies have disclosed less uniform results, although Dawson, Olmstead and Jost's²⁰ finding of precipitins to carbohydrate and protein fractions of the streptococcus in the serums of patients with rheumatoid arthritis may be considered as evidence favoring the claim of specificity. In contrast, then, to the three measuring sticks previously described, which are admittedly nonspecific, in this case we may be dealing either with a specific diagnostic test without etiologic significance (like the Weil-Felix and Wassermann reactions) or even one concerned with the causative organism.

METHODS

The group of patients studied numbered forty-nine. They all fulfilled the diagnostic criteria of rheumatoid arthritis in an active stage, patients with hypertrophic arthritis alone, gonorrheal arthritis and gout being carefully excluded. The majority of these patients have been followed since the initial period of observation, some for as long as four years. This enabled us to be

who never developed actual joint changes. On the selected group of patients fulfilling these requirements, 156 sedimentation tests, 141 Vernes tests, 102 Schilling counts and 132 streptococcus agglutination reactions (with four strains) were performed. Over half the patients were tested more than once, and many were followed at intervals of from four to six weeks for six months or more.

The patients along with the results of the various tests are listed in table 1. The extent of involvement and the degree of activity as well as the total severity were graded in each case at the time the tests were

performed. The subsequent fate of each patient is noted, with the duration of follow-up.

Sedimentation tests were done according to the method described by Rourke and Ernstene.²¹ In this method the factor of dilution is done away with by the use of heparin as an anticoagulant, venous stasis is avoided, and the tests are performed within three hours at room temperature (20-25 C.). The rate is measured during the period of most rapid settling and expressed in millimeters per minute. Readings of the distance the cells have fallen at the end of an hour or every fifteen minutes as employed in other methods are influenced by the packing of cells during the latter part of the period and by aggregation in the first part. Finally, the hematocrit is determined and correction made for the cell volume percentage of each specimen. In this way, false positives resulting from anemia are avoided. Any method which fails to correct for this anemia factor is subject to error and therefore is not to be relied on. We chose to use this method because along with other workers,²² we believed it less subject to inaccuracy than the older methods employed. Vernes resorcinol tests were performed according to the modified method of Baylis,¹⁴ as described. Doubtful readings, listed as \pm , were considered negative. Differential counts were done according to Schilling's²³ modification of Arneith's method. Band forms, juveniles and myelocytes were lumped together and the percentage of total polymorphonuclear leukocytes was reckoned. A count of young cells of over 8 per cent was considered a positive Schilling test. Agglutination reactions were performed following the methods described by Dawson and his co-workers.¹⁶ Dilutions of the serum were not carried out beyond 1:320, because previous work seemed to show no consistent correlation between the agglutination titer and the

clinical status of the patient. Readings were carefully made by two observers, with results declared positive only when definite agglutination was present. Serums agglutinating the organisms in a titer of 1:160 or over were considered positive, but only if the reactions in lower dilutions were stronger. In most cases, four strains of hemolytic streptococci were used, one (AB₁₃) a "typical" strain of Cecil's, recovered from a patient with rheumatoid arthritis, the others from nonarthritic patients. NY₅ was isolated from a patient with scarlet fever, and C₁₇ and RB₅ from patients with rheumatic fever. In figuring the results, if one of the four strains showed agglutination in a dilution of 1:160 or over, the test was considered positive.

RESULTS

In table 2 are shown the results obtained with each test. It will be noted that the sedimentation rate and the Schilling count show a high degree of correlation, with the former slightly ahead. In contrast, the Vernes test and the agglutination reaction are positive in only slightly over 50 per cent of these active cases of rheumatoid arthritis. In the case of the agglutination reaction, if we take each strain separately, results varying from 20 per cent (AB₁₃) to 34.6 per cent (C₁₇) are present. It is evident then that, as far as the diagnosis of activity goes, both sedimentation rate and Schilling count are far superior to the other two tests.

We have mentioned that the agglutination reaction has usually been found negative in the first six months of the disease.²⁴ Dawson, Olmstead and Boots¹⁸ also found a definite relationship between the duration of the disease and the agglutination titer of the serum and that patients having had the disease under a year showed positive agglutination tests in only 33 per cent compared to 71 per cent positive in the group of longer duration. Table 3 shows a similar analysis of our figures. We find only a slight difference between the two groups in the case of the Vernes test and the agglutination reaction. On the other hand, a marked difference is seen in the sedimentation rate, the Schilling count, and in agglutination of three of the streptococcus strains when considered

TABLE 5.—Relationship to Severity

Streptococcus agglutination reaction.....	Mild.....	11	33	55
	Moderate and severe	35	97	53

separately (C₁₇, NY₅ and AB₁₃). However, it must be remembered that any conclusions drawn from these figures may be misleading, since the first group was much smaller than the second. Furthermore, the first group contained fewer advanced cases. The majority of the first group were often tending to go into a remission following the initial attack. As regards the patients' age, we agree with Nicholls and Stainsby that there is not sufficient correlation with the results of the agglutination reactions to enable us to rule out other variables. The same is true of the other three tests.

As might be expected, only the sedimentation rate and Schilling count show any degree of agreement. In ninety-six instances in which the two tests were performed simultaneously on thirty-six patients, they agreed in eighty cases, or 83 per cent. When the other tests are similarly compared, agreement is seen only about 50 per cent of the time. Table 4 shows in percentage figures the proportion of instances when one test was diagnostic, i. e., positive, while the other was negative. Again, the sedimentation rate and Schilling count are superior, being incorrect in 10 per cent or less, while, if the Vernes test and agglutination reaction are compared with the other two, we find them excelled in 35 per cent or more instances.

In table 5 we have attempted to divide the cases into two groups, the first with few objective changes and a

COMMENT

In general, agreement is reported by other workers, as far as the reliability of the sedimentation rate is concerned. All disclose either 90 per cent or over of their cases of definite rheumatoid arthritis with increased sedimentation rate or, when actual figures are not given, uniform agreement of this test with the clinical diagnosis. In respect to Schilling or filament-nonfilament counts, conclusions are not unanimous, with results ranging from 52 per cent,²² 68 per cent,²⁵ 78 per cent²⁶ and 91 per cent²⁷ to 100 per cent.²⁸ In one large series,²⁷ the figures are rendered less valuable by the nondifferentiation of cases of rheumatoid and hypertrophic arthritis. The French workers²⁹ state that the Vernes test is of distinct value but give no actual percentages. In regard to the agglutination reaction,

* The majority of these patients with rheumatoid arthritis have been studied in great detail and have been followed in a special follow-up clinic since they first came under observation. The case number refers to the Massachusetts General Hospital rheumatoid arthritic series and will be employed in all subsequent reports pertaining to the detailed analysis of the statistical data collected on this group of patients since 1930.

relatively mild involvement and the second representing a more severe type of the disease, with many joints affected and often with ankylosis and deformity. In this, the agglutination reaction and Schilling counts show little difference in the two groups, while the sedimentation rate shows a slightly greater percentage of positive reactions in the second group and the Vernes test a marked difference.

A small number of cases of other types of arthritis were incidentally tested in the course of the study but have not been included in the tables. In these, the sedimentation rate was increased in two cases of acute gouty arthritis, five cases of gonorrheal arthritis and in over 50 per cent of tests performed on seven patients with hypertrophic arthritis, with the Vernes and Schilling tests showing a similar but lower number of positives. The agglutination reaction was positive in gout in one out of four tests, in gonorrheal arthritis in two out of six tests and in hypertrophic arthritis in two out of four. Results in so few tests are of course inconclusive but do point toward the nonspecificity of all four tests.

there is an interesting shift in the reported results. The first reports by Cecil, Nicholls and Stainsby¹⁷ showed nearly 100 per cent agglutinability of "typical" strains by serums from patients with rheumatoid arthritis. The analysis of the figures given in later articles shows a much lower degree of positivity (Dawson¹⁸ 67 per cent, Nicholls and Stainsby²⁴ about 40 per cent, Keefer¹⁹ 54.5 per cent, Cox and Hill¹⁹ 70 per cent, Blair and Hallman¹⁹ 84 per cent). The majority of the reported series approach more closely our figures (53.1 per cent). It must be remembered, however, that this percentage (53.1) in many instances applies to patients with serums agglutinating only one strain out of four. As shown in table 2, if the strains are considered separately, results from 20 to 34.6 per cent are obtained, with AB₁₃ (a "typical" strain of Cecil) lowest of all. We find a constant agreement, then, only in the case of the sedimentation rate.

25. Rawls, Gruskin, Ressa and Jordon.²⁵26. Steinberg.¹⁹27. Eaton.¹²28. Steinbrocker and Hartung.¹³29. Coste, Lacapère and Rapaport.¹⁵ Lacapère and Fénal.¹¹

There are a number of articles in the literature in which one of these tests is compared with another in a group of patients with rheumatoid arthritis. Dittges⁸ found seven cases out of thirty-seven in which the sedimentation rate was abnormal but without an associated increase in young polymorphonuclear leukocytes, an agreement of 81 per cent. In 210 simultaneous determinations done on fifty patients, Rawls and his co-workers¹⁰ found the two tests erring equally and agreeing in 77 per cent. Steinberg,¹⁰ in a smaller series, on thirty patients, concluded that the sedimentation rate was more accurate, with twenty-nine tests positive, while the Schilling count was increased in twenty-two instances. Agreement was seen in 78 per cent. Our own figures give the sedimentation reaction a slight advantage (92.2 to 87 per cent) and show agreement between the two tests in seventy-nine out of ninety-six tests, or 83 per cent. It would seem then that, although there is some variation in opinions expressed and figures given as to the value of the Schilling count when used alone, the results of direct comparison, with which our conclusions agree in the main, would place it nearly on a par with the sedimentation rate.

There are a few reports of simultaneous determinations of the Vernes test and sedimentation rate. One French author³⁰ believes that the former is less sensitive than the latter and does not always coincide. Others¹⁶ have found no especial parallelism and agreement in about two thirds of the cases. There is a suggestion then of corroboration of our finding that the Vernes reaction is far inferior (less than 60 per cent) to the sedimentation rate. We can find no reports of comparison between the Schilling count and the Vernes reaction. Again, the streptococcus agglutination reactions have been compared with other tests only twice—each time with respect to the sedimentation rate. Both Stainsby and Nicholls¹⁰ and Dawson, Olmstead and Boots¹⁸ state that the reactions are entirely unrelated. This is corroborated by our figures in regard not only to the sedimentation rate but also to the other two tests. In every case, agreement is present in 60 per cent or less, including the comparison with the Vernes reaction, an entirely nonspecific test but one showing a very similar percentage of positive tests in this group of patients with active rheumatoid arthritis.

Until the etiology of rheumatoid arthritis is known, the question of the specificity of the agglutination reaction will not be settled. Results with normal and pathologic control serums would show that when positive it approaches a diagnostic test, although certain exceptions render the distinction not entirely clear cut. The variations in agglutination titer in one patient in a comparatively brief time, not accounted for at present by clinical developments, may be seen in table 6 (excerpted from table 1). Patients 48, 125 and 181 all show wide swings from negative (1:80 or below) agglutination titers to positive in periods of a month or less. This unreliability has been brought out in Nicholls and Stainsby's paper²⁴ and by Cox and Hill.¹⁹ This variation is shared by the Vernes reaction (see patients 175, 182 and 195 in table 6), while the sedimentation rates and Schilling counts tend to remain relatively constant. The finding by Tillet and Abernethy³¹ of non-specific agglutinins for hemolytic streptococci (not heat killed but incubated at 37 C.) in various infections is suggestive that the suspension stability of this organism

may respond, like the red blood cells, to changes in the plasma proteins. At any rate, when we employ the agglutination reaction as a test for the presence of active rheumatoid arthritis we find that it is easily surpassed by two and equaled by one of three admittedly non-specific reactions.

Which of the four tests are of practical value for the clinician and really useful in following the disease? We believe at present that the agglutination reaction, while it may be of definite value in the investigation of this disease, both from difficulty of technic and from lack of uniformity of results, is not indicated in the routine study and treatment of patients with rheumatoid arthritis. The Vernes test, although simple in performance, suffers from relative inaccuracy (at least as shown by our results), and the degree of turbidity must be approximated unless a photometer is used. Results in the literature would indicate even more than our figures that the sedimentation rate is superior to the Schilling count. The latter, in addition, does involve a more laborious technic than the sedimentation rate, which should be further simplified and improved when photographic methods³² are perfected. In doubtful cases, in which the sedimentation rate is negative, the performance of a Schilling count in addition might be of diagnostic significance.

In our later experience we have employed the sedimentation rate alone as the best "measuring stick" of active disease in the case of rheumatoid arthritis. In several thousand tests on all types of joint disease, we have found it entirely nonspecific but a valuable laboratory guide. We hope to report this large series of results in a subsequent paper.

SUMMARY AND CONCLUSIONS

1. On a group of forty-nine patients with active rheumatoid arthritis, four commonly employed "measuring sticks" were evaluated.

2. The sedimentation rate was found positive in 92.2 per cent of the tests, with the Schilling count only slightly less accurate (87 per cent). The Vernes test and streptococcus agglutination reactions were positive in approximately 50 per cent (58.3 and 53.1 respectively).

3. In cases of a year's duration or under, the sedimentation rate and the Schilling count were positive less often than in cases of longer duration. The other two tests showed approximately similar results in each group.

4. The sedimentation rate was slightly more accurate in severe than in mild cases. The Vernes test was markedly so, while the other two showed little difference.

5. Our results agree in the main with those reported in the literature.

6. From the standpoint of practicability and accuracy, the sedimentation rate is the most useful laboratory test thus far in common use to aid in the recognition and evaluation of patients with active rheumatoid arthritis.

THE TREATMENT OF HEART DISEASE COMPLICATING PREGNANCY

H. J. STANDER, M.D.
AND
KATHERINE KUDER, M.D.
NEW YORK

That the heart output increases during pregnancy has been demonstrated in both animals and the human being.¹ In a normal pregnancy the cardiac output begins to increase at about the fourth month, from which time on there is a steady rise until term is reached. This increase in cardiac output during normal gestation, expressed in terms of volume of blood passing through the heart in unit time, is approximately 50 per cent. Following delivery the minute volume slowly returns to normal, reaching its nonpregnant level within four weeks. Unfortunately, as yet, we are ignorant of the cardiac output or work during the period of labor, although there is reason to believe that it is further augmented during parturition.

It is evident that such a marked increase in the minute volume of the heart during gestation must be of

Chart 1.—Average cardiac output during normal pregnancy.

the utmost importance in patients suffering from some cardiac disturbance. This additional work placed on the heart as a result of pregnancy and labor may be more of a strain than the diseased organ can stand, and the outcome may be, and often is, heart failure resulting in death. The proper care of a pregnant patient with heart disease is one that taxes the best judgment of the obstetrician, and whenever possible he should have the cooperation of a well trained cardiologist or internist.

In order that pregnant patients suffering from cardiac involvement may obtain the best possible care during the antepartum period, the Lying-in Hospital maintains an antepartum and postpartum cardiac clinic, manned by the departments of obstetrics and medicine of the New York Hospital, of which the Lying-in Hospital is an integral part. The patients attending this cardiac clinic are seen and examined by both the obstetrician and the cardiologist at frequent intervals throughout the antepartum period. The details of treatment and hospitalization will be discussed later.

From the Department of Obstetrics and Gynecology, Cornell University Medical College and New York Hospital.

Stander, H. J., and Cadden, J. F.: The Cardiac Output in Pregnant Women, *Ibid.* 24:15 (July) 1932.

A study of 563 hospital discharges, representing 418 pregnant patients suffering from cardiac disease and cared for in the Lying-in Hospital during the period Sept. 1, 1932, to Dec. 31, 1936, is the basis for this paper.

INCIDENCE

During the period studied, four and one-third years, there were 14,157 obstetric patients discharged from the hospital, and of this number 563 were discharged with the diagnosis of cardiac disease, an incidence of 3.97 per cent. As stated in a previous publication,² we are convinced that more importance should be placed on cardiac disease as a complication of pregnancy, especially because of this high incidence of about four in every hundred gravid women and because of the effect pregnancy has on this complication.

MORTALITY

In table 2 we present the maternal and infantile mortality in the group of cardiac patients, as compared to the mortality rates for all the patients in the Lying-in Hospital during the period studied, and labeled in the table as "total clinic patients," a term we use in subsequent analyses, with identical meaning. It will be observed that the maternal death rate in the cardiac group is more than twice as high as in the group of "total clinic patients," being 7.1 per thousand in the former and 2.8 per thousand in the latter. The infantile mortality remains approximately the same in the two groups. It should be noted that we consider the term "infantile mortality" to include all stillborn and deadborn infants weighing more than 1,500 Gm. as well as those babies dying during the first two weeks following birth.

The types of cardiac lesion encountered are shown in table 3. Patients suffering from mitral stenosis and insufficiency constitute more than 40 per cent of all cardiac patients, while approximately 20 per cent have both mitral and aortic lesions. Mitral stenosis alone accounts for 18 per cent of the cases, and aortic lesions for only 1.44 per cent. It is interesting that only two, or 0.48 per cent, of the 418 patients had definite congenital heart lesions. From this table it is clear, as Carr and Hamilton³ have pointed out, that rheumatic heart disease accounts for about 90 per cent of the cases.

Although we have been hesitant² to adopt the functional classification of heart disease, it has now become with us an established method of studying heart disease in pregnancy. The reason for this is that by experience we have found that this classification is of greater value in the evaluation of the cardiac involvement and thus a better aid in prognosis than the old anatomic classification, as used in table 3. This classification of the New York Heart Association is based on the functional capacity of the heart and is as follows:

Class 1. Patients with organic heart disease able to carry on ordinary physical activity without discomfort. Ordinary physical activity does not cause undue fatigue, palpitation, dyspnea or chest pain. Patients in this class do not show physical signs of cardiac insufficiency and rarely signs of active heart infection.

Class 2. Patients with organic heart disease unable to carry on ordinary physical activity without discomfort.

(a) Activity slightly limited. Ordinary physical activity causes undue fatigue, palpitation, dyspnea or chest pain. Patients in this class rarely show physical signs of cardiac insufficiency or signs of active heart infection.

2. Stander, H. J.: Cardiac Disease in Pregnancy, *Am. J. Obst. & Gynec.* 27:528 (April) 1934.

3. Carr, F. B., and Hamilton, B. E.: Five Hundred Women with Serious Heart Disease Followed Through Pregnancy and Delivery, *Am. J. Obst. & Gynec.* 26:824 (Dec.) 1933.

(b) Activity greatly limited. Less than ordinary physical activity causes fatigue, palpitation, dyspnea or chest pain. Patients in this class usually show one or more physical signs of cardiac insufficiency or the anginal syndrome or signs of active heart infection.

Class 3. Patients with organic heart disease and with symptoms or signs of cardiac insufficiency, at rest, unable to carry on any physical activity without discomfort. There is fatigue,

palpitation, dyspnea or chest pain at rest. Patients in this class show marked physical signs of cardiac insufficiency or the anginal syndrome, or signs of active heart infection.

It will be seen that class 2 cardiac patients, i. e., those with organic heart disease who are unable to carry on their ordinary activity without discomfort, but not with symptoms or signs of cardiac insufficiency at rest, are further subdivided into two groups, 2a and 2b. The former subgroup rarely reveals physical signs of cardiac insufficiency or infection and in general is able to go through pregnancy and even labor without untoward developments, provided careful supervision is employed. Class 2b cardiac patients, on the other hand, generally show signs of cardiac insufficiency and may readily become decompensated. It is because of this serious possibility that we prefer to regard class 2b as clinically similar to the definite class 3 group, in which are the patients with cardiac insufficiency at rest, and in the part of this paper dealing with treatment we shall discuss the class 2b and class 3 in one group. This, we believe, is to the best interests of the patient.

In table 4 we have grouped the 418 cardiac patients according to this functional classification. Unfortunately the hospital records are not clear enough on 151 of these patients to permit a definite grouping, and we have therefore thought that it would give a more correct index of incidence to list separately the 267 patients in whom the classification was definite and well established. In this group we find that class 1 accounts for 51.69 per cent, class 2a for 34.46 per cent, class 2b for 11.98 per cent, and class 3 for 1.87 per cent. Fortunately, therefore, the majority of our cardiac patients, i. e., over 86 per cent, fall into classes 1 and 2a, the two mild types, and only about 14 per cent belong in the severe types, classes 2b and 3. Of the four women who died as a result of heart disease in our group of 418 patients, two definitely belonged to class 3, and the other two probably belonged in class 2b.

A definite history of either rheumatic or scarlet fever, chorea or frequent sore throat was reported in 58.4 per cent of the 387 cardiac patients, and from only slightly more than 40 per cent were we unable to elicit such a

history. It is apparent, therefore, of what great significance a careful past history becomes in the routine care of all pregnant women.

In table 6 we give the type of delivery in the cardiac patients. Approximately 8 per cent of these patients had an abortion, by which we indicate delivery prior to viability, or of a fetus weighing less than 1,500 Gm. Of the remaining 386 cardiac patients, 69.1 per cent had spontaneous deliveries and 30.9 per cent an operative type of delivery.

As many of the operative deliveries, shown in table 6, were not performed because of the cardiac disease, we have constructed table 7, which is an analysis of all types of intervention or operative delivery done because of the heart disease. This shows that, for this indication, about 3 per cent had a therapeutic abortion, 4 per cent cesarean section and 12 per cent forceps delivery. It may be said then that, in one out of every five pregnant women suffering from cardiac disease, interruption of the pregnancy or operative delivery becomes the procedure of choice.

The last table (table 8) is a comparison of the maternal deaths from cardiac disease and those from the other common causes in our clinic during each year from 1932 to 1936 inclusive. The comparison is most instructive, since it places cardiac disease as one of the most important causes of maternal mortality, contrary to the usual teaching. The clinic population in our hospital is not a selected group but is made up of both registered and unregistered patients, of all types and races; i. e., a fair representation of a cross-section of the city population.

Cardiac disease accounted for 10 per cent of all uncorrected maternal deaths in our total indoor and out-

door obstetric service during a four and one-third year period. The total uncorrected maternal mortality, including abortions and ectopic pregnancies, in this combined service is 2,251 per thousand patients discharged, or 2.324 per thousand live births.

TREATMENT

It is most essential that in every maternity hospital all pregnant patients with heart disease be studied in a special cardiac clinic throughout their antepartum

period. Every pregnant woman who comes to register at a hospital, clinic or physician's office should have a careful and complete examination, in which particular attention is paid to the heart. Too often is this neglected, and the patient proceeds to term with an unrecognized but easily demonstrable heart disease. The possibility of a cardiac lesion is one of the many rea-

sons, and an important one, that all pregnant women must see a physician as early in pregnancy as possible. It is our practice that when heart disease is suspected or diagnosed the patient is immediately referred to our special cardiac clinic, where a thorough reexamination is performed. Should the condition warrant it, the patient is admitted to the hospital for a complete study of her cardiac condition; otherwise she is followed at frequent intervals in the cardiac clinic.

In general we may say that patients with class 1 or class 2a heart disease can be safely cared for in the office or antepartum cardiac clinic until about two weeks before term, at which time they should be hospitalized. This statement, however, should not be taken too literally, as each patient must be treated individually, as symptoms or signs may develop that make it imperative to admit to the hospital a class 2a, and sometimes even a class 1 cardiac patient, a month or more before the expected date of delivery. The pulse and respiration rates are among the best indications as to the behavior of the heart. Undue fatigue, palpitation, dyspnea and

chest pains are further signs of which a careful note and record must be made. An untoward development in any one of these is sufficient cause to hospitalize and provide forced rest in bed—the best treatment for most of these cases. The patients in class 1, and many of those in class 2a, will deliver spontaneously after two weeks' rest in the hospital, without undue rise of the pulse and respiration rates during labor. However, it is well to use forceps on full dilatation of the cervix in

a certain number, the maternal pulse and respiration rates being used as the main index for such intervention. A pulse rate of over 110 and respiration rates of 28 or over are sufficient reasons to save the patient the further strain on the heart incidental to the voluntary muscular work of the second stage of labor. It must be emphasized that any anesthesia producing partial asphyxia, such as nitrous oxide, is contraindicated in the delivery of cardiac patients. We prefer ether anesthesia, administered by the open drop method, for all our cardiac patients.

In patients belonging definitely in class 2b and class 3, much earlier and longer hospitalization is essential. It is often necessary to readmit the patient to the hospital two or more times during the pregnancy. An analysis of the hospital admissions of our 418 cardiac patients reveals the fact that of this number, twenty-two women had 136 hospital admissions before delivery, an incidence of approximately six admissions per patient. Forceps delivery, to obviate the second stage of labor, is performed far more frequently in these patients. The use of digitalis compounds is of great help, in our experience, in preparing these patients for the ordeal of labor. This may also be said for those patients in whom we perform cesarean section because of the heart condition. When the patient is definitely in class 3, our treatment is more radical than in the class

2b patient. When there has been a definite break in compensation either prior to or during the pregnancy, we generally advise cesarean section with sterilization. Such patients are admitted to the hospital early in pregnancy; adequate rest and digitalis therapy is provided and the section is performed when the patient has attained her optimum condition and no further improvement appears possible. The operation is performed under open drop ether anesthesia and in the presence of a competent internist. During the past four and one-third years we have performed such cesarean sections on patients definitely in class 3 and have lost only one mother. Of course, it is not advisable to allow some of these class 3 cardiac patients to proceed to viability, and therapeutic abortion or miniature cesarean section becomes the treatment of choice. In our 418 cardiac cases, therapeutic abortion for the heart condition was performed in twelve.

An analysis of the past history as well as careful questioning of our 418 cardiac patients revealed the astounding fact that 189, or 49.8 per cent, of them were wholly unaware that they had cardiac disease. This finding further impressed us with the absolute necessity of a careful heart examination on every pregnant woman at her first visit to her physician.

The important factors in the handling and treatment of cardiac disease in pregnancy are:

(a) All pregnant patients must consult their physician early in pregnancy.

(b) A thorough examination, including the heart, must be made at the time of the first visit.

(c) If the past history, symptoms, signs or examination reveal heart disease, however mild, the patient should be followed in a special cardiac clinic or by her physician in consultation with a competent internist.

(d) All pregnant patients with cardiac disease must be in a hospital during the last two weeks of gestation and must be delivered in the hospital.

(e) Patients with class 1 and 2a heart disease may be delivered spontaneously, provided the pulse and respiration rates are not markedly augmented or no untoward symptom or sign such as dyspnea or cyanosis develops, in which event it is advisable to obviate the second stage of labor by the application of forceps on full dilatation of the cervix.

(f) Patients in class 2b and class 3 should be hospitalized early in pregnancy in order that as accurate an evaluation of the cardiac reserve as possible may be made in order to decide whether or not the pregnancy should be allowed to proceed.

(g) Should it be deemed advisable to interrupt the pregnancy, it becomes the obstetrician's further responsibility to decide whether a therapeutic abortion followed by birth control, a therapeutic abortion followed by tubal sterilization or a miniature section with sterilization is the proper treatment. This decision will

depend on a number of factors, such as the age and parity of the patient, the duration of the pregnancy, the number of living children, the desires of the patient and her husband and, lastly but most important, the severity of the cardiac involvement.

(h) On the other hand, should it be deemed advisable to let the pregnancy proceed to viability or full term, the patient may have to remain in the hospital for months or be readmitted several times during the pregnancy in order to maintain a careful and vigilant watch over the cardiac condition. It may be necessary to digitalize the heart and to continue digitalis therapy.

(i) The treatment, when viability or term is reached, in this relatively small but important group of patients will depend on the cardiac condition in each individual. When there has been a history of definite cardiac failure and the heart is now compensated, it is our practice to perform a cesarean section with tubal resection. In the other patients in this group it is usually advisable to deliver by forceps.

(j) No anesthesia producing varying degrees of asphyxia should be used in cardiac patients, at the time either of delivery or of operation. Open drop ether anesthesia has given us the best results.

(k) Cardiac patients who are first seen or admitted to the hospital in labor with acute heart failure must be placed in an oxygen tent and delivery effected as soon as possible, but consistent with sound obstetric

principles. So far we have delivered none of this group of patients by cesarian section. Cardiac stimulants, such as ouabain, are of course of the utmost assistance in these patients.

Three charts are presented to portray the behavior of the pulse and respiration rates in a class 2a cardiac patient delivered spontaneously, in one in which forceps delivery became advisable and in a class 3 cardiac patient delivered by cesarean section, respectively. It is in the cardiac patient that the pulse and respiration rates assume particular importance, since they so frequently become the main indication for operative intervention. Both charts 2 and 3 show the manner in which these rates return to normal shortly after delivery is effected.

SUMMARY

There is a definite effect of gestation on the cardiac output, as shown by experimental work on the minute volume in both animals and the human being. The amount of work performed by the heart starts to increase during the first trimester of pregnancy and at term is approximately 50 per cent above the normal nonpregnant level. There can be

Chart 2.—Spontaneous delivery in class 2a cardiac disease.

Chart 3.—Forceps delivery in class 2a cardiac disease.

little doubt, although as yet we have no experimental proof, that labor demands a further and perhaps marked increase in the minute volume of the heart.

In our series 418 pregnant patients suffered from cardiac disease. About 85 per cent of these patients had the milder types of involvement, which we group as class 1 and class 2a heart disease. The remaining patients, representing 15 per cent of the total, suffered

from serious heart disease (class 2b and class 3) and form the group in which occurred our maternal deaths from heart disease. To a large extent cardiac disease accounts for the total uncorrected maternal mortality in a series of 18,207 consecutive obstetric discharges during a four and one-third year period in the Lying-in Hospital.

CONCLUSIONS

1. In 14,157 obstetric patients discharged from the hospital, the incidence of cardiac disease is 3.97 per cent.

2. The maternal mortality is almost three times as high in cardiac patients as in the total hospital patients.

3. Rheumatic heart disease accounts for more than 90 per cent of our pregnant cardiac patients.

4. We are of the definite opinion that the functional classification of the New York Heart Association is of more value as an aid in the treatment of the pregnant patient suffering from heart disease than is the anatomic classification.

5. Only about 41 per cent of the group of 418 cardiac patients studied gave no history of rheumatic fever, scarlet fever, chorea or frequent sore throat.

Chart 4.—Cesarean section with sterilization in class 3 cardiac disease.

6. About 50 per cent of the 418 cardiac patients were wholly unaware, at the time they first consulted a physician in their pregnancy, of the existence of a cardiac disease.

7. Hospitalization and complete rest are the greatest aids in the treatment of heart disease in pregnant women.

8. Digitalis and its compounds are of definite help in the severe types of this disease.

9. Increased pulse and respiration rates, dyspnea and cyanosis, undue fatigue, palpitation and chest pains are the outstanding signs and symptoms in the evaluation of the cardiac condition.

10. The treatment in class 1 and class 2a cardiac patients consists of hospitalization two weeks before term, followed by spontaneous delivery or in a small number forceps delivery at the beginning of the second stage.

11. The severe types, class 2b and class 3, must be hospitalized earlier in pregnancy in order to decide whether the pregnancy should be allowed to continue, and, if so, delivery should be effected by forceps unless the patient falls in the class 3 category.

12. In those patients who have had a definite break in compensation it is advisable, after adequate hospitalization with digitalis therapy, to perform a cesarean section either at viability or at term, followed by sterilization.

GEORGE L. DIXON, M.D.

TUCSON, ARIZ.

The influence of climate on the prevalence, course and clinical picture of rheumatic fever has been much discussed though seldom accurately measured.¹ Wide-spread differences in clinical concepts about this disease which exist in different places, difficulties in clinical diagnosis and the absence of specific diagnostic tests have made it practically impossible to determine its prevalence with accuracy in any given locality, much less to compare its prevalence in several localities. Despite the lack of accurate data, however, there is general agreement that the disease is common and severe in temperate zones, that it is less common in warmer and subtropical climates, and that it is rare in the tropics.² But comparative prevalence determinations in which identical diagnostic criteria have been used in different geographic or climatologic locations are practically nonexistent. Consequently it has been the major object in this work to make such determinations under conditions that were moderately controlled.

METHODS

For measuring the geographic prevalence of rheumatic heart disease we have determined the rates (or percentage) of such cases as could be found among three groups of Indian school children in northwestern and southwestern sections of this country. The choice of these Indian populations has rested on the fact that there is a general similarity from the standpoint of race among some North American Indian tribes which is not found among other groups of Americans, and also that, regardless of their geographic locality, there is a general similarity of their living conditions. Furthermore, within certain Indian reservations in this country many of the adults and almost all of the younger children have spent their lives within a few miles of the place of their birth. Their illnesses, therefore, should be truly representative of local, living and climatic conditions. In fact, several such groups of Indians may furnish more valuable information about

The expenses of this work have been defrayed by the Milbank Memorial Fund.

From the Department of Internal Medicine, Yale University School of Medicine, New Haven, Conn., and the Desert Sanatorium, Tucson, Ariz.

1. Accurate determinations on the prevalence of a disease which is not reportable are difficult enough to obtain but particularly difficult in a disease in which there is no diagnostic test, such as rheumatic fever or its sequelae. Data from hospital admission lists throughout this country or from private practice are of some value, though admittedly inaccurate. See discussion of Nichol's^{2a} paper and Climate and Rheumatic Fever, editorial, J. A. M. A. 108:210 (Jan. 16) 1937.

2. Most of the recent literature on this subject has been summarized by (a) Nichol, E. S.: Geographic Distribution of Rheumatic Fever and Rheumatic Heart Disease in the United States, J. Lab. & Clin. Med. 21:588 (March) 1936. See also (b) Coburn, A. F.: The Factor of Infection in the Rheumatic State, Baltimore, Williams & Wilkins Company, 1931.

the geography of disease than do most school populations in this country. Particularly is this true of the Southwest, a region which has been included in this survey, where the white school population contains a large percentage of recent immigrants from other regions.

A final controlled condition used in this study is that the same methods of gathering data and the same diagnostic criteria have been applied by the same two examiners in the different locations studied.

In planning the study, a section of the West was first outlined and a number of Indian reservations within this section were chosen (fig. 1). Permission for the privilege of proceeding with this work was first obtained from the Office of Indian Affairs, U. S. Department of the Interior.³ The reservations were then divided into a northern, a middle and a southern division, from which comparable groups of children could be examined. As will be seen from the map in figure 1, the two northern reservations (representing Crow, Shoshone and Arapahoe Indians) were located in Montana and Wyoming; the middle reservations (largely representing Navajo Indians) were located in northern New Mexico and northern Arizona, and the southern reservations (representing Pima and Papago Indians) were located in southern Arizona. It will also be seen that the middle group is not separated from the southern one by nearly as great a distance as it is from the northern one. But in spite of their proximity to one another the isothermal lines show a difference of 20 degrees F. in the average temperature (which is largely the result of a difference in altitude) between the southern and the middle group, and this is considerably greater than the temperature difference of 5 degrees F. existing between the middle and the northern group.

Another climatic condition that concerns the areas under surveillance appears in figure 2. Here the degree of moisture (precipitation) is shown on the sectional map. It will be seen that all the Indian reservations surveyed were in fairly dry areas but that the southernmost group is in a region with precipitation figures ranging from only 3 to 10 inches a year.

It was our object to examine about 1,000 children of the same age distribution from each of these three (northern, middle and southern) groups.

DIAGNOSTIC CRITERIA

Obviously the diagnosis of clear-cut rheumatic heart disease offers little difficulty, but mild cases offer considerable difficulty. Most of the cases encountered in a survey of this type are mild, and of course inactive, and unfortunately the diagnosis of just such forms as these requires a large element of personal judgment. It has been our effort throughout, however, to include only the more definite cases.

In approaching the problem we have assumed from the onset that the great majority of children showing rheumatic carditis will present evidence of mitral insufficiency or stenosis and that in such cases systolic or presystolic murmurs will probably be present in the region of the cardiac apex. In justification of this approach it should be emphasized that we have followed the rule that most systolic murmurs do not indicate the presence of any organic heart disease.

Nevertheless a search for such murmurs generally represented the starting point of our cardiac examinations.

All the examinations recorded in this study were performed by one of us, and most of the doubtful cases were seen by both of us. In the actual performance of the cardiac examinations the following procedure was used:

The children were stripped to the waist and unless abnormal conditions were present were examined only in the erect position. A few features besides those referable to the heart were included; namely, the degree of nutrition, evidences of infection of the upper respiratory tract and the size of cervical lymph nodes. For the cardiac examination the hand was placed on the precordium and the point of maximum impulse located.

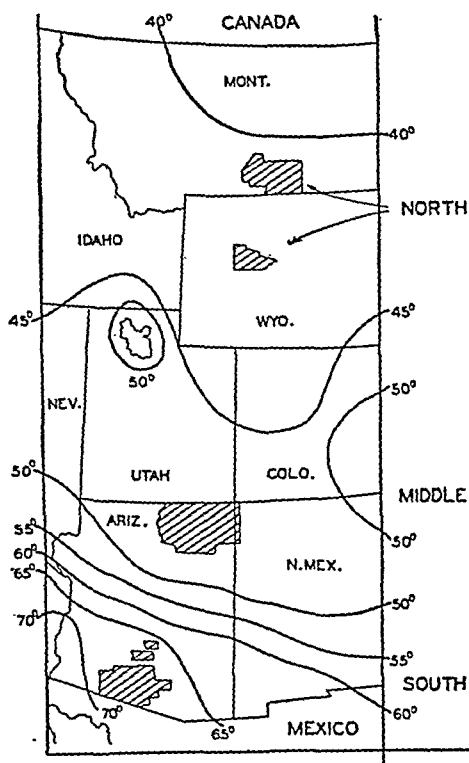

Fig. 1.—Sectional map of the United States showing (by shaded areas) the locations of the three groups of Indian reservations included in this study. The series of curved lines (isotherms) indicate average annual temperatures.

The stethoscope was then placed on the apical region, the midprecordium and the base of the heart. If no abnormalities were found on palpation and auscultation, the child's heart was considered normal. No attempt was made to determine the size of the heart by percussion, unless abnormalities detected either by palpation or auscultation were found. The usual time consumed in the examination of children with normal hearts was about two minutes per child.

As a rule we paid little or no attention to soft systolic murmurs heard only at the pulmonic area and have not included them in the recorded results. All murmurs heard in the midprecordium were, however, recorded. Of these, systolic murmurs were the most frequently heard, and we have classified them arbitrarily, i. e., regardless as to where they seemed to arise, into three types, according to the diagram in figure 3.

Type I systolic murmurs represent a loud murmur, usually maximal in the general region of the apex,

3. Dr. J. G. Townsend, Director of Health, Office of Indian Affairs, Washington, D. C., gave this permission, and many medical officers in the Indian Service, whose names are too numerous to mention here, were generous in their cooperation and support of this work.

which can be heard in the area indicated; that is, besides covering the midprecordium it extends laterally beyond the left nipple line and often downward. Such murmurs were present in the majority of cases that we have listed as definite rheumatic heart disease.

Type II represents a systolic murmur which is not as loud as type I and can be heard laterally as far as the left nipple line but not beyond. It is in the interpretation of these type II murmurs as to whether they

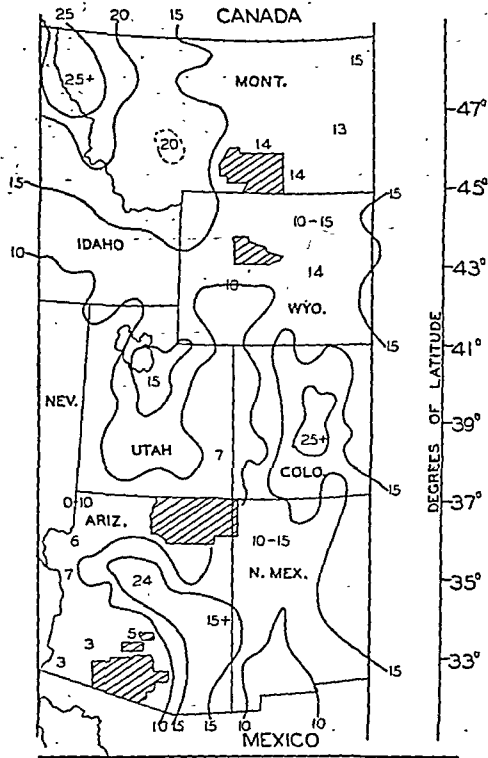

Fig. 2.—Sectional map, similar to that in figure 1, showing by isohyetal lines or scattered figures the normal annual precipitation (expressed in inches). Degrees of north latitude appear on the right of this map.

were "functional" or "organic" that we have met our greatest difficulty, and in their presence we have examined the heart as carefully as the circumstances would permit, and with the subject lying on his back and also on his left side.

Type III is represented by a soft systolic murmur which is heard in the midprecordium but is also heard in the pulmonic area and is not transmitted laterally. It is our impression that the great majority of these murmurs are transmitted from the base downward. From the onset of this survey we did not consider them as of much significance as far as the diagnosis of rheumatic heart disease is concerned, and evidence accumulated in the course of the study substantiated this belief.

In interpreting our type II and III systolic murmurs as a starting point in the diagnosis of rheumatic heart disease, the following other aids to diagnosis were occasionally used:

A history of rheumatic fever, if present, was regarded as of positive importance in the presence of questionable cardiac signs. Such histories were obtained, however, in a very small number of questionable cases.

Some of the other signs, which have been regarded as aids to a positive diagnosis, were the presence of cardiac enlargement that could not be explained on any other basis, an increase in the area of impulse to the left, accentuation of the first sound at the apex, accen-

tuation of the pulmonic second sound, and accentuation of the murmur when the patient was lying on his left side.

The diagnosis of congenital heart disease rested on the cardiac manifestations, the presence of cyanosis, clubbing of the fingers and the history.

RESULTS

Rheumatic heart disease rates found in the school children within the three areas covered by this survey appear in table 1. For their proper interpretation they should be compared with similar rates determined in school children from other sections of this or other countries, but unfortunately few such comparisons can be made. For, although there are many statistics on the observed prevalence of heart disease in school children, they have been largely compiled from data obtained in the course of routine physical examinations in which the diagnostic criteria for either heart disease or rheumatic heart disease have not been defined and the methods of examination of the heart have of necessity been more cursory than those employed here. This question has been discussed in a previous publication in which juvenile, organic heart disease rates ranging from 0.1 to 2.1 per cent have been collected from the literature (up to 1934) and tabulated geographically.⁴ It is our impression that such crude rates, so far as they concern rheumatic heart disease, are considerably lower than those which would have been found in this survey. This impression has been strengthened by the fact that, using the identical methods outlined in the present report, one of us (J. R. P.) has previously determined the prevalence of rheumatic heart disease in a group of school children within the city of New Haven, Conn., and found it to be considerably higher than that obtained the previous year by the school physicians.⁴

But to return to the figures in table 1. Here it appears that Indian children from certain of the northwestern reservations show a high rate of rheumatic heart disease. It happens to be twice as high as that (2.2 per cent) determined by the same method among urban New England school children living at a somewhat more southern latitude, although in a climate far more damp. Among the thirty-one children found to have rheumatic heart disease in the northwestern Indian

Fig. 3.—Diagrammatic cardiac outlines on which are indicated the sites (shaded areas) where the three types of systolic murmurs recorded in this study were heard. The small circle roughly marks the site of the left nipple.

group, about a third of them proved to have mitral stenosis, and also in about a third of them a history of an illness compatible with rheumatic fever was obtained. In about half of the latter group (with a story of illness) hospital records were available. These results indicate that the Crow, Shoshone and Arapahoe Indians, which were the northern tribes observed, are

4. Paul, J. R.; Harrison, E. R.; Salinger, Robert, and DeForest, G. K.: The Social Incidence of Rheumatic Heart Disease: A Statistical Study in New Haven School Children, *Am. J. M. Sc.* 188:391 (Sept.) 1934.

quite susceptible to rheumatic fever and that they often suffer from its most serious complication.⁵ No difference in the rheumatic heart disease rates was found among these three different northern tribes and no apparent difference between those of mixed blood as compared with those of pure blood.⁶

In the middle division of Indian reservations (from northern Arizona and New Mexico—largely representing Navajos) the rheumatic heart rate was found to

TABLE 1.—*Rheumatic Heart Disease Rates in Three Different Locations**

Location of Reservations	Latitude North	Climatic Conditions		No. of Indian Children Examined	No. with Definite Rheumatic Heart Disease	Per Cent with Rheumatic Heart Disease
		Temperature	Precipitation			
North	44°-46°	42.5°	10-14	688	31	4.5
Middle	26°-37°	47.5°	7-10+	1,106	21	1.9
South	32°-33°	67.5°	3-10	1,019	5	0.5

* For purposes of comparison, attention is called to the fact that the prevalence of rheumatic heart disease has been found to be 2.2 per cent among 2,624 urban and rural school children similarly examined in 1934 in and about the city of New Haven, Conn.⁴

† Approximate average normal temperature for the year in degrees Fahrenheit.

‡ Normal annual precipitation in inches.

be 1.9 per cent, or less than half that found among the tribes farther north. Here again a third of the twenty-one Indians proved to have mitral stenosis and in about the same percentage a history compatible with that of rheumatic fever was obtained.

In the southernmost group (southern Arizona—largely representing Pimas and Papagos) rheumatic heart disease was found to be rare. Only five cases were found in about 1,000 children examined, and there was only one case of mitral stenosis.

OTHER HEART ABNORMALITIES

Mention has been made that the presence of various (three) types of systolic murmurs (fig. 3) was recorded in the course of this survey. Actual prevalence figures for each type are not listed in this report but it is of significance that our type III, midprecordial systolic murmurs (heard also at the base, rather than laterally) were found with equal prevalence in all three (northern, middle and southern) groups. This is in sharp contrast to the geographic prevalence of our type I murmurs (transmitted laterally) and is a finding having some bearing on the clinical interpretation of systolic murmurs.

Examples of congenital heart disease (or congenital cardiac abnormalities) are limited to those types which are most apt to be detected by auscultation alone. Seven such cases (about 0.2 per cent) were found in the entire number (2,813) of children examined. Included among these seven was one case of dextrocardia and two definite cases of patent ductus arteriosus. The remaining four were probably examples of inter-ventricular septal defects.

Other cardiac conditions included one case of old tuberculous pericarditis, five cases of unexplained cardiac enlargement, three of unexplained tachycardia and three of extrasystoles.

5. A high prevalence of rheumatic heart disease has been previously recorded among another Northern American Indian tribe; namely, the Menominees in northeastern Wisconsin. Hrdlička, Aleš: Tuberculosis Among Certain Indian Tribes of the United States, Bull. 42, Smithsonian Institution, Bureau of American Ethnology, Washington, D. C., Government Printing Office, 1909.

6. This is in contrast to the results found in tuberculosis among some of these same Indian tribes in which a relationship between the degree of Indian blood and the incidence of tuberculous infection was found. Aronson, J. D.: Personal communication to the authors.

Extracardiac abnormalities noted in the course of our examinations which are worth mentioning include the high and more or less equal prevalence of mild infections of the upper respiratory tract—largely colds, present in all three groups (northern, middle and southern), the high and almost equal frequency with which enlargement of the posterior cervical lymph glands was encountered, and the high prevalence of infestations of the scalp with pediculus capitis.

POSSIBLE SOURCES OF ERROR

Obviously the rheumatic heart disease rates listed in table 1 cannot be satisfactorily compared with one another without a consideration of the factors that may influence them. For instance, unless the children from each major geographic division are of comparable age, the carditis rates are not comparable.⁷ The age distribution of the children in these three divisions is not identical, but their degree of similarity is sufficient to allow a comparison of several of the different age groups. This appears in table 2. The three age groups of 7 to 9, 10 to 12, and 13 to 15 years offer the most significant figures.

Another point that may have some bearing on our observations is the difference in physical types and degree of nutrition existent between Indians of some of the different tribes. This has been well illustrated by the difference between the Arapahoe children of the North and the Pima children of the South. Arapahoese are plains Indians, for the most part "meat eaters," and the children, at least as they were brought in from their homes at the opening of the schools, often appeared undernourished. Pima Indians are agricultural and subsist largely on a carbohydrate diet, and the children under similar circumstances were often greatly overnourished. In comparing the weights of Indian children from these two tribes with the average normal weights of white American children of comparable ages and heights, we found that about 45 per cent of the

TABLE 2.—*Rheumatic Heart Disease Rates in Different Age Groups*

		Age Groups*					
		5-6	7-9	10-12	13-15	16-19	19+
North division	Number of children in age group.....	80	204	209	142	49	4
	Per cent with rheumatic heart disease.....	0	3.9	8.1	4.2
Middle division	Number of children in age group.....	61	153	203	312	297	75
	Per cent with rheumatic heart disease.....	0	4.4	2.0	1.5	1.3	1.3
South division	Number of children in age group.....	114	226	229	227	77	6
	Per cent with rheumatic heart disease.....	0	1.0	0.3	0	1.3	..

* Rates have not been determined unless the age groups contain more than fifty children.

Pima children were "overweight" (10 per cent being as much as 35 pounds [16 Kg.] or more "overweight") and but 8 per cent were "underweight," whereas among the Arapahoe children 15 per cent were "overweight" and 41 per cent were "underweight." Consequently in determining the rheumatic heart disease rates in

7. A serious source of error may exist in data concerning the age of North American Indians. In some tribes the parents do not seem to know the ages of their children. Under these circumstances "ages" have been assigned to many of the children in this series by school teachers. Some appreciation of their accuracy can be obtained from height weight tables. It is our impression that about two thirds of the ages recorded in our series are reasonably correct. In the other third (and this applies mainly to the middle division) there is a probable error in many of the children of about \pm 1 year.

these two particular groups of Indian children the difference lies not only in their geographic separation but also in their physical type. In one group there is a large percentage of apparently undernourished children with thin chest walls and easily heard heart sounds, and in the other there are many fat children with thick chest walls. What effect this difference in degree of nutrition may have on the actual prevalence of rheumatic heart disease is, of course, unknown, but what effect it may have on the detection of mild cases of rheumatic heart disease should be considered. Some cases of rheumatic heart disease may have been overlooked in the Pima children, owing to the poor audibility of heart sounds and perhaps to the difficulty in determining the size of the heart. This may have influenced our results, but it is our belief that such a source of error has been slight. Even if the error in this group were as great as the omission of one case of rheumatic heart disease in every 100 children examined, our results would still point to an appreciable decrease in the rheumatic heart disease rates in the Southwest as compared with the Northwest.

COMMENT

It has been intimated earlier in this article that the influence of climate on the prevalence of rheumatic fever is a subject much discussed but less frequently defined and that there has been a dearth of accurate data on the subject. Despite this lack of accurate data there has been, however, general agreement that the disease is common and severe in the temperate zones, that it is less prevalent in warmer (subtropical) climates, and that it is rare in tropical climates. With this impression the results presented in this paper in general agree, and certain figures are presented which we believe are significant because of the moderately controlled conditions under which they have been obtained.

On the other hand, there has been little general agreement as to whether the clinical picture of rheumatic fever is the same in the North as in the South. It has even been suggested that the southern form of the disease may be characterized by the absence of joint symptoms and, without these warning signals of acute arthritis and chronic muscle pain, rheumatic carditis may develop in the south more insidiously and with greater frequency than is generally supposed.⁸ From our own results the notion that rheumatic carditis may develop with considerable unsuspected frequency in the Southwest finds no support, for regardless of the fact that the northern rate used for comparison was found to be unusually high (4.5 per cent) the southern rate (0.5 per cent) seems unusually low.

The high rate (4.5 per cent) found among the northern Indian tribes raises a question of some interest because the element of cold, or more particularly dry cold, has not usually been regarded as the sole climatic feature that favors a high prevalence of the disease. On the other hand the element of cold coupled with dampness has long been incriminated as one of the primary conditions favoring the spread of rheumatic fever,

as has also the influence of crowding, such as urban as opposed to rural life. Consequently, it is remarkable to find a higher prevalence in relatively dry Montana and Wyoming (normal annual precipitation from 10 to 15 inches) among rural Indian children than that found among urban children in the vicinity of New York City (normal annual precipitation 45 inches). This suggests that either a high susceptibility exists for the disease on the part of some Indians or that something is present in their living conditions that is particularly conducive to the spread of the disease. Whatever such factors may be, they remain to be analyzed. Attention may be called, however, to the fact that although the Indians included in this survey represent a rural (as opposed to an urban) population, the degree of crowding that must occur during the winter months among their family groups probably rivals or even exceeds that found within tenement houses in city slums; for the Indian family group often includes three generations, their winter dwelling is generally a one room affair, and Montana winters are long.

SUMMARY

The different rates with which rheumatic heart disease may be found in school children in different sections of this country is a valuable method for determining the geographic prevalence of rheumatic fever. Groups of Indian school children are particularly favorable for such determinations because of their homogeneity from the standpoint of race and of living conditions and because of the stability of the populations within many of the Indian reservations of the West.

From a survey of Indian children it has been shown that in the cold though relatively dry climate of Wyoming and Montana the prevalence of rheumatic heart disease (4.5 per cent) is high, in comparison with rates determined in New England (2.2 per cent), whereas in the warm though dry climate of southern Arizona it is correspondingly low (0.5 per cent). In other words, rheumatic heart disease is almost ten times as frequent among western Indians living in regions close to the Canadian border as it is among similar groups living close to the Mexican border.

It is probable that the clinical course of rheumatic fever in the Southwest may be milder than that usually encountered in the North, but no evidence was found in this survey suggesting that the apparent mildness of the clinical picture of rheumatic fever in the Southwest may allow rheumatic heart disease to develop with an unsuspected frequency comparable to that seen in more northern climates.

Theory of Cause of Allergy.—Studying a large number of allergic families and comparing them with normal controls, Haag has come to the conclusion that there is no evidence that allergic diseases may be considered psychoneuroses or that mental conflict is of any major significance in their etiology. Since a hereditary predisposition is the basis of allergic diseases, all positions in the family circle should show equal incidence of such disease. Since first-born children in all families and youngest children in large families showed the greatest frequency of allergic diseases, some special factor must be present there. The author finds an explanation in the type of nutrition. First-born children, and the youngest children, where older brothers and sisters spoil them, receive special care and are frequently overfed. He regards overfeeding in childhood of significance in producing allergic diseases.—Feinberg, S. M.: *Progress in Asthma and Hay Fever, J. Allergy* 8:289 (March) 1937.

BASAL PERICARDITIS

A SIGN OF EARLY RHEUMATIC INFECTION

JOSEPH B. WOLFFE, M.D.
AND
VICTOR A. DIGILIO, M.D.
PHILADELPHIA

There are numerous difficulties in making a diagnosis of a low grade active rheumatic state. The laboratory has been of little service in this regard. One of us¹ observed adventitious friction-like murmurs, somewhat musical in character, in the majority of children who at various times experienced one or several symptoms of childhood rheumatism, such as muscular and joint pains, paroxysmal abdominal pain,² sore throats, stiff neck, involuntary twitchings resembling tics,³ pallor, weight fixation and persistent low grade elevation in temperature (to be found only when carefully looked

The adventitious sound of mild plastic rheumatic pericarditis is best heard in the region of the left second and third costosternal junctions, although it may also be heard at the apex. It is friction-like, musical (at times) and of variable quality—from faint to harsh. It is apt to be systolic in time but is often diastolic and only occasionally of the double or “to and fro” type, and it has no definite points of transmission but may be audible over surrounding regions, depending on its volume. Its intensity and character often vary from beat to beat. It is never totally obliterated by deep inspiration, although the phases of respiration do alter its volume somewhat. It becomes louder with the patient in the prone position. It is accompanied by an accentuated second pulmonic sound.

This friction-like murmur at times may be inconstant; indeed, transitory. It may disappear some variable time following the arrest of the disease process, although in most cases it is present for many years after the

Differential Diagnosis*

Murmur	Mild Pericarditis†	Mitral Stenosis	Mitral Regurgitation	Functional
1. Time.....	May be systolic or diastolic; may vary during a single examination; rarely “to and fro”	Presystolic or diastolic	Systolic	Systolic
2. Character.....	Friction-like but variable	Rough, rumbling type	Soft, blowing	Soft
3. Intensity.....	Second left costosternal junction; occasionally also at apex but may vary during a single physical examination	Apex	Apex	Base of heart (pulmonary area); occasionally at apex
4. Transmission.....	None	May be audible in axilla (but not transmitted)	To axilla and back	None
5. Stability of character and intensity	Exceedingly changeable in intensity and character; it may vary from beat to beat, from examination to examination, from day to day	Fixed in character; may vary in volume, depending on cardiac action	May change over a period of many months or years if organic, owing to contraction of the scar around the orifice and slow development of mitral stenosis‡	Not variable, except after exercise
6. Age frequency.....	Seen in early childhood, 3 years to 12 years	From 12 years up, most frequent past 15 years	Any age	Any age
7. Percussion dulness.....	Normal size	Slightly enlarged	Left sided hypertrophy	Normal size
8. Roentgenogram.....	Straightening out of left border	Prominent pulmonic cone and left auricular hypertrophy, and frequent dilatation	Mitral configuration	Normal size, shape and position, unless murmur is caused by dilatation of valve ring
9. Electrocardiogram.....	Frequently normal with exception of occasional changes seen in the active rheumatic state	P wave changes; right axis deviation	Left axis deviation	Normal
10. Outcome.....	Frequently disappears	Permanent, as a rule, in presence of sinus rhythm	Permanent if organic; functional type may disappear	May disappear permanently

* The material for this table has been collected from our own case histories, Temple University Heart Station, Torresdale and Willow Crest convalescent homes.
† Differentiated from aortic valvulitis by the fact that the murmur of the latter is usually transmitted up to the vessels of the neck.
‡ This may account for the rarity with which one finds mitral insufficiency in adult life.

for). From our studies, these friction-like, at times somewhat musical, murmurs appear to be the earliest objective signs in low grade childhood rheumatism and are apparently due to pericarditis at the base of the heart, in the region of origin of the great vessels, involving the fold of the pericardium at the point of reflexion of the latter structure. The sulcus between the aorta and the pulmonary artery is an excellent dam for the accumulation of inflammatory exudates or transudates. It may be looked on as a peripulmonitis and periaortitis, although it is not entirely confined to these areas.

arrest of the rheumatic phase. It is noteworthy that, in quite a number of cases presenting this sign, orthodiagrams or teleroentgenograms reveal a straightening of the left border of the cardiac silhouette.

A differential diagnosis may be made between the adventitious sound due to mild plastic pericarditis and other murmurs in the usual accepted manner, as shown in the accompanying table.

A boy, aged 7 years, was referred from the pediatric clinic to our cardiac clinic because the child complained of anorexia and restlessness and the mother wanted a “good tonic” in order to build him up. It was most difficult to obtain a history from the mother, but after persistent grilling she admitted that the child would come to her bed at nights under the pretext of pain in the knees or ankles, but she knew it was only because he did not want to sleep by himself.

1. Wolffe, J. B.: Arch. Pediat. 50: 832 (Dec.) 1933.
2. Wolffe, J. B., and Brim, C. J.: The Abdominal Syndrome of Rheumatic Disease in Childhood, Am. J. Dis. Child. 52: 296 (Aug.) 1936.
3. Wolffe, J. B., and Sleane, Paul: Concepts in the Treatment of Chorea, Arch. Neurol. & Psychiat. 32: 662 (Sept.) 1934.

On physical examination we found the throat injected; the tonsils had been cleanly removed. The cervical glands were enlarged and slightly tender. The heart was slightly enlarged to the left and was overactive. The rate was 93 per minute. A loud systolic murmur was heard at the apex and base of the heart. Some members of the clinic thought that the murmur was transmitted to the axilla, while others felt that it was audible only because of its loudness. There was also a short systolic murmur heard over the second right costosternal junction, slightly transmitted to the vessels of the neck. The second pulmonic sound was accentuated.

The record further reveals that various members of the clinic recorded the time and character of the murmur at variance with their own previously recorded observations. The consensus was that the child suffered from a low-grade active rheumatic state, mitral valvular disease with regurgitation and aortic valvular disease.

The teleroentgenogram revealed a changing silhouette and a straightening out of the left border. The heart enlarged 1.5 cm. in nine months. The child's mother was very uncooperative.

One and a half years after attending the clinic this child was killed by an automobile. The autopsy taught us to reinterpret some of the adventitious sounds that we had thought to be due to valvular disease. The left ventricle was found to be slightly larger than normal. The pericardium was injected; at the base of the heart, around the entire area of the aortic and pulmonic sulcus, was a fuzzy, reddish, cotton-like fibrinous exudate, loosely adherent to the parietal and visceral pericardium. The mitral and aortic valves were injected but not distorted to the extent that the diagnosis of mitral regurgitation was justified. Aschoff bodies were found in the septum.

Several similar observations were made by us, one in an 11 year old girl who died of acute fulminating meningitis who showed signs of childhood rheumatism, on and off, and a boy of 6, who died as a result of uncontrollable chorea. The cardiac pathologic changes were similar to those described.

The excellent recent work of Gross⁴ has lent additional pathologic support for the existence of this sign; he says:

It has been mentioned that all of the active rheumatic cases presented in the peripulmonic sheaths either a microscopic pericarditis or an acute, exudative pericarditis and that in the inactive rheumatic series many cases showed scattered lymphocytes and large mononuclear cells in this area. It seems possible that this inflammatory condition of the pericardial mantle bears a causal relation to the markedly increased capillarization of the great vessel roots.

Many careful observers have been cognizant of these adventitious sounds. Their interpretation of it varies. In some clinics it is interpreted as a functional murmur and in others it is attributed to a mitral insufficiency due to dilatation of the mitral ring. Some interpret it as a mitral insufficiency or stenosis, disease of the pulmonary artery or aortic valvulitis, depending on the location of the murmur and the point of maximum intensity.

The frequency with which plastic pericarditis is seen escapes attention only because the disease at this stage is not fatal and the lesion is transitory in character and precedes the later valvular lesions by many years. It is well known that children who are properly cared for will conquer the active rheumatic phase and after several years the heart will be found to be perfectly normal on physical, x-ray and electrocardiographic examination. On the other hand, those who are treated symptomatically with so-called tonics, whose activities are not restricted, who are allowed cold water bathing during the summer and permitted to wear inadequate

clothing during the winter, with foci of infection overlooked, after a time show evidence of permanent cardiac pathologic changes.

The proper interpretation of these adventitious sounds is important. It prevents us from making the unwarranted diagnosis of fixed and irreparable valvular disease in cases in which the disease has not progressed to a stage of permanent pathologic state. It also acts as a suspicion arouser.

Every additional aid in the diagnosis of low grade active rheumatic disease should prove of utmost importance. It helps to focus attention on a very common, insidious disease which, when overlooked, often leads to permanent cardiac damage that may be preventable in the greater number of cases.

ARTERIOSCLEROSIS AND THROMBO-ANGIITIS OBLITERANS

REPORT OF CASES AND TREATMENT

ALICE R. BERNHEIM, M.D.

AND

ISABEL M. LONDON, M.D.

NEW YORK

Since the work of Buerger, who described the characteristic lesions of the vascular walls in thrombo-angiitis obliterans and thus distinguished it from other diseases of the blood vessels, attention has been directed, quite naturally, toward the differences between this disease and arteriosclerosis rather than to those features which they have in common.

Reports in the literature record several kinds of medical treatment of thrombo-angiitis obliterans which have resulted in arrest of the disease and a marked reduction in amputations, but we have failed to find reports of similar treatment applied in cases of arteriosclerosis. We have stressed the features common to the two diseases and, with therapy based on the likenesses of rather than on the differences between the two, we have obtained results in arteriosclerosis even more favorable than those in thrombo-angiitis obliterans.

The decreased peripheral blood supply in both diseases is due in part to functional constriction of the blood vessels and in part to organic changes in their walls, which cause them to become permanently narrowed and rigid. Increase in the viscosity of the blood was found in both diseases in our series. Vasospasm was a factor of as much importance in arteriosclerosis as in thrombo-angiitis obliterans, except in the advanced cases in which the walls of the vessels were rigid. In both diseases the vessels, particularly those of the extremities, were apparently unduly sensitive to vasoconstricting influences, as shown by skin temperature and oscillometric measurements after exposure to cold, after the use of tobacco and as the result of deficient diet. Vasoconstriction in these cases was prolonged beyond the normal response into more or less continuous vasospasm.

Patients with peripheral vascular disease often go first for treatment to the orthopedic surgeon, and since many of these patients have flat feet or some other orthopedic disorder the arterial disease, until far advanced, has all too frequently been overlooked. How-

4. Gross, Louis. *Am. J. Path.* 11: 631 (July) 1935.

From the Clinic for Peripheral Vascular Diseases, Department of Surgery, New York Hospital and Cornell University Medical College.

ever, recently the orthopedic surgeon has come to recognize early peripheral vascular disease—so much so that in some cases he has failed to treat a coexisting orthopedic condition after making a correct diagnosis of arterial disease. Thanks to these early diagnoses, the majority of the patients in our present series were seen before the vessels were entirely rigid and when the vasospastic element was still one of importance. Twenty-four of the ninety-nine patients with arteriosclerosis had had symptoms of only a few months' duration.

Our experience suggests that vasospasm is an underlying process in both diseases, without which other causative factors might be inoperative. Discussion of this point, however, is beyond the scope of this report, since from the point of view of treatment it is immaterial whether vasospasm is of primary or of secondary importance.

Obviously the aim of treatment is to increase the supply of blood to the extremities, and this we attempted to do first by relieving vasospasm, which results in the dilatation of those vessels with resilient walls, and, secondly, by decreasing the viscosity of the blood, which results in its easier passage through even narrow and rigid vessels.

TREATMENT OF VASOSPASM

Treatment consisted in the use of measures to eliminate five vasoconstricting influences: tobacco, improper diet, worry, undue physical exertion and cold.

1. *Tobacco*.—Those patients who continued to smoke or chew tobacco against advice failed to improve. While the discontinuance of the use of tobacco without other measures was insufficient to bring about lasting improvement in symptoms, we have found no lasting improvement in either disease without it.

It was not sufficient simply to tell the patient not to smoke or chew tobacco. Most of the patients had used it excessively for years. Many had been advised by physicians previously to stop its use but only two had done so. It was necessary to warn them clearly and repeatedly that unless they gave up tobacco completely and for good they could not improve and might even lose their limbs.

2. *Dietary Regimen*.—The patients were given a regimen high in calcium and vitamins because of its favorable influence on vasospasm. This regimen was given, however, even when the vasospastic element was apparently absent, as shown by failure of the skin temperature of the foot to rise after nerve block, because all the patients had been on diets deficient in calcium and in some of the vitamins and because of the general good effects of a diet enriched by these substances.

The chief sources of calcium were milk and cheese. When it was not feasible to include them in the diet, calcium salts were given instead. Concentrates of vitamin A and D were added, vitamin B was given in some form of wheat germ or yeast, and vitamin C was supplied in orange juice and tomato juice.

The dietary schedule given in table 1, designed for the optimum absorption of calcium, was used.

When for any reason milk could not be included in the diet, calcium was supplied in the form of the lactate or gluconate; 2.5 Gm. of calcium lactate, and 5 Gm. of calcium gluconate are equivalent in calcium to a pint of milk. To favor absorption these salts were administered at special times; namely, no nearer meals than four hours after and one hour before. The patients who did not drink milk received two doses of calcium salts a day, while those who drank a pint of milk

received one dose. In some cases with a history of unusually marked dietary deficiency in calcium one dose of calcium salts was given for a period of several weeks or more, in addition to the quart of milk in the diet.

Lactose was added to the diet of patients suffering from constipation, except in cases of diabetes. From two to six heaping tablespoonfuls a day effectively regulated the movements of the bowels in the majority of cases. Lactose may cause diarrhea, so that it was necessary to find by trial the amount suitable for each person. Increase in intestinal gas, which sometimes follows the use of lactose, was found to abate usually within the course of a few weeks.

Approximately 19,000 units of vitamin A, and 1,900 units of vitamin D (U. S. P. XI) were given daily in tablet form, three tablets twice a day, for several months.

3. *Worry*.—It was considered an important part of the therapeutic schedule to help the patient to gain insight into whatever domestic, economic or social difficulties might be disturbing him and to aid him in adapting himself to his limitations.

4. *Undue Physical Exertion*.—It is desirable that the work done by individuals with peripheral vascular disease be commensurate with their diminished peripheral

TABLE 1.—Diet Designed for Optimum Absorption of Calcium

	Required Food	Other Food Allowed
Breakfast	Orange or grapefruit juice Wheat germ (2 or 2 table- spoonfuls) Milk, 1 pint	Any fruit (raw or cooked) Coffee or tea, with sugar Bread, 1 slice, or 1 roll, with butter
Mid-day meal	Milk or buttermilk, 1 pint Vegetables (except potatoes, rice, spaghetti, corn) Fruit	Cheese Eggs* Bread, 1 slice, or 1 roll, with butter †
Evening meal	Tomato juice (any good canned variety, not the ready-prepared cocktail; seasoning may be added) or Pineapple juice Meat or fish	Any other foods desired

There should be intervals of at least five hours between meals
Nothing should be eaten between meals

* Eggs may be taken at breakfast if preferred.

† One starchy vegetable may be substituted for the bread.

blood supply. Accordingly, patients were advised against exertion to the point of pain in the extremities. During the early period of treatment in the clinic, or until considerable improvement was attained, as much rest as possible was advocated. Passive exercises as described by Buerger were considered an important part of the therapy. Patients were instructed to perform these exercises two, three or four times a day according to the following directions:

1. Lie down flat in bed, with shoes and stockings removed.

2. Raise both legs vertically into the air, bending them at the hips so that the soles of the feet face the ceiling. If this position is painful or impossible, the legs may be raised as nearly vertical as possible or may be rested against a wall to the side of the bed or against a chair placed on the bed.

3. Keep the legs raised exactly one minute (by the clock.)

4. Lower the legs; sit up in bed with the legs hanging freely over the edge of the bed (not touching the floor).

5. Keep the legs in this position for exactly one minute (by the clock). While they are hanging over the edge of the bed move the feet slowly back and forth and from side to side, at the ankle joint.

6. Lie down flat in bed; rest for one minute in this position.
7. Repeat entire process five times (that is, six times altogether).

5. *Cold*.—The following instructions were given for keeping the extremities properly warm: In cold weather out of bed the patient should wear (1) white cotton socks, over them (2) woolen stockings covering the knees, (3) woolen underwear, (4) fleece-lined shoes if

much outdoors and (5) no tight or ill fitting shoes. In bed (1) he should wear very loose woolen stockings, or cotton wadding, 1 to 2 inches thick, made into boots to cover the feet, legs and knees and (2) he should use an electric light bulb (under a cradle) only if thermostatically regulated at temperatures of from 92 to 93 F.

Hot water bags and other heating pads were forbidden. Warm soaks for the feet and legs once or twice a day were advocated as follows:

1. Use one-half cupful of kitchen salt in 1½ gallons of warm water. Water should be comfortably warm—not too hot—soapsuds of castile soap may be used instead of salt, if preferred.

2. Soak feet once or twice a day for thirty minutes.

3. Dry feet thoroughly, being especially careful to dry the toes and the spaces in between the toes. Do not dry them roughly, taking care that the skin is not injured.

4. Dust plain talcum powder over and between the toes, so that you are sure the toes are dry.

Very light massage is allowed. We have failed to see good results from the use of diathermy, baking or hot and cold contrast baths; in fact, in a number of cases symptoms have become definitely worse after the use of these measures. Extremes of temperature are to be avoided, and heat may be as harmful as cold. Heat increases the metabolism of the tissues, which then require more blood, and, while vasodilatation is also produced by the heat, the impaired vessels are not able to supply sufficient blood for the added demand.

THE ADMINISTRATION OF SODIUM CITRATE

Sodium citrate was given from the beginning of treatment in all cases presenting severe symptoms, and it was given in other cases when improvement did not

follow the foregoing dietary regimen. It was administered by mouth when it was not feasible to give it by vein.

Sodium citrate reduces the viscosity of the blood, but the mechanism that brings this about is unknown.

Decreases in viscosity of from 1 to 2 points, which lasted for twenty-four hours or longer, followed the intravenous injection of 250 cc. of a 2 per cent solution of sodium citrate. Viscosity readings were not repeated in all the cases, but in some after a course of injections the reduction was apparently permanent, while in others the viscosity was lowered only during the period of injections and returned to its previous high level when injections were discontinued.

The normal viscosity ranges from 4 to 5.5 (average 4.5) while the range in our cases of arteriosclerosis and thrombo-angiitis obliterans was from 5.4 to 8 (average 6.5). Measurements were made with the Hess viscosimeter, in which columns of blood and water are compared in capillary tubes.¹

The benefit from the administration of sodium citrate in these two forms of peripheral vascular disease apparently does not come only from its effect on viscosity. In some cases, with initial viscosity readings within normal range, relief of symptoms speedily followed its use. Other chemical changes are produced by sodium citrate in the body, such as lowering of the fibrinogen of the blood and increasing the excretion of calcium, but we are without knowledge of their possible influence. Contraindications to the use of sodium citrate by vein are auricular fibrillation and cardiac disease with decompensation. Some hold the opinion that intravenous therapy is contraindicated in diabetes,

Divisions on
Oscillometer

A reading of 1 signifies a swing of the oscillometer needle from 1 to 2, or from 2 to 3. A reading of 2 means a swing from 1 to 3, or from 3 to 5; 3 means a swing from 1 to 4.

but in some of the cases with this complication the good effects that followed the use of sodium citrate—relief of pain, healing of ulcers—were especially prompt in occurrence, and in none of the cases were any ill effects noted.

Unpleasant reactions—chills, fever, nausea and vomiting—may occur after the giving of sodium citrate as they do after the administration of other substances

1. Substitution of a mouthpiece for the rubber bulb on this instrument makes the handling of the test easier and the readings more accurate.

by vein, because of too speedy injection or insufficient cleaning of new rubber tubing, and they may also occur as a result of the method of preparing the solution.² These reactions, however, are avoidable, and no ill effect has occurred following daily injections given for many months. In one case as many as six injections a week for six months were given. In a

calcification of the vessels. Only twelve cases of thrombo-angiitis were so examined, and calcified vessels were seen in only one case.

OSCILLOMETRIC READINGS

The oscillometer determines the amplitude of arterial pulsation in a limb. Measurements are taken at the foot, ankle, calf, thigh, wrist and arm. Table 4 shows the range of oscillometric readings in the normal individual and in patients with arteriosclerosis and thrombo-angiitis obliterans in this series.

Oscillometric readings were reduced at the foot and ankle in all but three cases, or 98 per cent, and in these the disease was confined to the digital vessels. When symptoms occurred in one extremity only, readings were usually diminished in the other as well, though to a lesser extent. The upper extremities were involved in three cases of thrombo-angiitis obliterans (5.5 per cent) and in one case of arteriosclerosis (1.01 per cent).

We have analyzed the oscillometric readings according to the number of determinations rather than according to the number of cases because of the differences so frequently found between the two extremities in the same individual.

In the cases of thrombo-angiitis 160 determinations were analyzed. Of these seventy-five were at the level of the foot and eighty-five at the level of the ankle. Following treatment they showed thirty-six increased; three decreased and thirty-six unchanged at the level of the foot, and fifty-three increased, ten decreased and twenty-two unchanged at the level of the ankle. The range of increase or decrease may be seen in table 5.

few cases relief of pain dramatically followed two or three injections of the sodium citrate, but the average course consisted of three injections a week for about three months. In the beginning of treatment of the severest cases, daily injections of 250 cc. were given. These were reduced to three or two a week as improvement progressed. The solution was given at a rate of from 7 to 8 cc. per minute, an injection time of from thirty to thirty-five minutes for 250 cc.

ANALYSIS OF CASES

Ninety-nine cases of arteriosclerosis of the extremities and fifty-four cases of thrombo-angiitis obliterans have been treated according to the method described and have been followed from six months to three and one-half years.

Eighty-three patients in the arteriosclerotic group and all the patients with thrombo-angiitis obliterans smoked tobacco.

X-RAY EXAMINATION

X-ray examination of the vessels of the extremities was made in only twenty-two of the cases of arteriosclerosis. Of these, seventeen showed marked

Unimproved	5	4
Ulcer	24	7
Improved	20	6
Unimproved	4	1
Gangrene	1	2
Improved	0	1
Unimproved	1	1

It may be seen that the largest number showed increases varying from a trace to one fourth at the foot, and from one fourth to 1 at the ankle.

There were thirty initial readings of zero at the foot level. Of the thirty readings, twenty-two were increased and eight were unchanged. Of the increased readings, sixteen increased to a trace, five increased to one eighth, and one increased to one fourth.

2. The following method of preparing sodium citrate was developed after considerable experimenting and is entirely satisfactory. Materials: (1) sodium citrate, c. p. tested purity, (2) sodium chloride, c. p. tested purity, (3) potassium biphosphate, monobasic, c. p. tested purity, (4) freshly distilled water, (5) "hardened" filter paper No. 575, Schleicher & Schuell, (6) suction flask, with metal filter cone (Berkefeld filter may be used instead of the filter paper). Method: 1. Dissolve 80 Gm. of the sodium citrate and 12 Gm. of the sodium chloride in 4 liters of freshly distilled water. 2. Allow to stand for thirty minutes. 3. Test the pH. If the pH lies between 7.2 and 7.6, proceed to the filtration. If not, adjust by the addition of a small amount (tip of a teaspoon) of potassium biphosphate. 4. Stand for thirty minutes, read the pH, and adjust if necessary. 5. Filter. 6. Pour into liter flasks. 7. Allow to stand for twenty minutes. 8. Inspect each 1 for cloudiness or "floaters." The citrate until clear of "floaters," then poured into liter flasks, which are covered with glass or metal caps fitting closely over the long necks of the flasks. The flasks are then autoclaved. After autoclaving the solution may be kept in the liter flasks for several months.

In the cases of arteriosclerosis there were 263 determinations: 121 at the level of the foot and 142 at the level of the ankle. They showed, after treatment, fifty-six increased, fifteen decreased and fifty unchanged at the level of the foot, and seventy-eight increased, twenty decreased and forty-four unchanged at the level of the ankle. The range of increase or decrease is given in table 6.

		11	37	6				16	74	9	
Amputations = 2, 1 above the knee, 1 of a toe						Amputations = 3 above the knee					

ence on this relationship. Among those with readings of zero were several elderly persons with elevated blood pressure, whose extremities were warm and showed only slight color changes, and who had pain only on exertion. In these cases the high blood pressure increased the flow of blood through patent though narrowed and undilatable vessels, so that the supply was evidently adequate for a state of rest. On the other hand, some of the cases with only moderately reduced oscillometric readings presented severe symptoms. In these cases the blood pressure was too low to supply a sufficient onward thrust to the blood for proper nutrition of the extremities, even though some vessels were still capable of dilatation.

Increase in oscillometric readings cannot always be correlated with improvement in symptoms. Improvement in symptoms depends on increase of blood flow to the affected parts, which may be brought about by relief of vasospasm, widening and increase in number of small vessels (development of collateral circulation), increase in blood pressure, increase in blood volume and decrease in blood viscosity.

In the presence of narrowed vessels, incapable of dilating, improvement in symptoms may follow changes in the quality or increase in the volume of the blood, and in such cases oscillometric readings would not be increased. On the other hand, oscillometric readings might increase, but not sufficiently to be accompanied

TABLE 10.—Relationship Between the Duration of Symptoms and the Degree of Improvement

Thrombo-Angiitis Obliterans					Arteriosclerosis				
Duration of Symptoms	Unimproved	Improved			Unimproved	Improved			
		*	**			*	**

10+ years.....	3	4	1		1	5	1		
		11	37	6		16	74	9	

These results are similar to those in thrombo-angiitis, except that in this group changes up to one half occurred in 8 per cent of the readings, while in thrombo-angiitis they occurred in only 2 per cent. There were forty-three initial readings of zero at the foot level and eleven at the ankle. Increases occurred in twenty-eight of the forty-three readings and in ten of the eleven. They were distributed as in table 7.

These tables show that initially reduced readings did not improve enough to be classed within the normal range, except at the ankle in two cases of arteriosclerosis. When the initial readings were zero, the majority increased to a trace only.

Readings at the foot and ankle were taken every three to six months under as nearly like conditions as possible. They were taken as the last part of the examination of the patient when he was relaxed and at ease and when the extremities were warm. Warm baths or blankets were used to raise the temperature of persistently cold extremities.

Reduction in oscillometric readings, in the presence of normal cardiac output and blood pressure, may be correlated with diminished distensibility of the blood vessels. Under these conditions decreased dilatation is due either to vasospasm or to changes in the vascular walls with loss of their elasticity.

For the most part the cases with oscillometric readings of zero presented the severest symptoms. Blood pressure, however, was seen to exert a modifying influ-

by any marked improvement in symptoms. This occurred in eight cases of thrombo-angiitis obliterans and in ten cases of arteriosclerosis.

SYMPTOMS

The cases of thrombo-angiitis obliterans and those of arteriosclerosis presented like symptoms—pain on effort (including intermittent claudication), pain when at rest, ulcer and gangrene. We have analyzed these symptoms in terms of severity, type and response to treatment. Other symptoms that frequently occurred in both

groups were swelling, numbness, tingling and coldness of the extremities. Severity was reckoned as

- + = pain on walking more than one block (200 feet).
++ = pain on walking less than one block, and/or when at rest.
+++ = ulcer or gangrene.

Of the patients with thrombo-angiitis obliterans, fifteen were classified as +, fifteen as ++ and twenty-four as +++ severity. Of those with arteriosclerosis, fifty-one were classified as +, thirty-eight as ++ and ten as +++ severity.

Improvement in symptoms was reckoned as

- * = absence of pain when at rest, ulcers healed, some increase in walking distance.
** = absence of pain when at rest, ulcers healed, marked increase in walking distance.

Correlation between severity of symptoms and improvement is shown in table 9.

Of the unimproved cases in the two groups, only four and three respectively presented the severest symptoms.

Table 10 shows the relationship between the duration of the symptoms and the degree of improvement.

In thrombo-angiitis obliterans, improvement failed to occur in three long-standing cases in which symptoms had existed for more than ten years. On the other hand three cases with symptoms of one year's duration and two cases in which symptoms had been present for only six months likewise failed to show improvement. In arteriosclerosis thirteen of the sixteen failures occurred in cases presenting symptoms ranging in duration from only three months to two years. These results indicate that duration of symptoms did not exert marked influence on improvement.

The effect of the patient's age on improvement is shown in table 11.

In forty-three of the fifty-four cases of thrombo-angiitis obliterans, symptoms appeared in the second, third and fourth decades. Nine of the eleven failures were in this group. Of eight cases in which symptoms appeared in the fifth decade, only two failed to improve. In the arteriosclerotic group only one of eighteen cases in which symptoms appeared in the sixth and seventh decades did not improve. Advance in age in this series of cases did not prevent improvement of symptoms.

RESULTS OF TREATMENT

The results of treatment have been analyzed as shown in table 12. The dietary regimen and proper physical care, including Buerger's exercises, soaks and the like, were used throughout in all the cases. In addition, sodium citrate was given in the severe cases from the beginning of treatment and in other cases when improvement did not follow diet alone. In a few cases presenting persistent cramp, calcium was given by vein. In addition to the treatment outlined, sedatives were freely used for pain when necessary. Acetylsalicylic acid 0.6 Gm., with codeine 0.06 Gm., given once or twice a day, proved adequate in most of the cases.

It was not always possible to foretell how soon improvement might be expected. Some of the cases presenting ulcer or gangrene, in which early improvement seemed unlikely, showed remarkably speedy response to treatment. In some of the other cases improvement did not occur for from four to six weeks or even longer. Accordingly, unless symptoms actually became worse, treatment was continued in some cases for from two to three months, until it appeared reasonably sure that improvement would not take place.

REPORT OF CASES

The following cases have been selected as examples of their kind and for their response to treatment.

CASE 1.—S. R., a man, aged 83, in fairly good physical condition, complained of severe cramps in both legs for the past six months. His past history was negative except for a deficient diet. He smoked six cigars a day. For the past three months he had been able to sleep only with sedatives. He was unable to walk more than half a block without pain. His feet were cold and white. Previous treatment with massage, diathermy and hot and cold contrast baths did not improve his symptoms. X-ray examination of the vessels of both lower extremities showed considerable calcification. The dorsal pedal and posterior tibial arteries were not palpable. The oscillometric readings were reduced throughout both lower extremities. He was given the dietary regimen, 2.5 Gm. of calcium lactate orally, Buerger's exercises three to four times a day, warm soaks twice a day, and acetylsalicylic acid 0.6 Gm., with codeine sulfate 0.06 Gm. at night, when necessary. Smoking was prohibited. He was instructed to return to the clinic in two weeks. At that time injections of sodium citrate were to be given if improvement did not follow. These injections, however, were not necessary, since after four days the pain at night was entirely gone, he could walk several blocks without pain, and at the end of two weeks he was completely free from symptoms. The oscillometric readings had increased nearly to normal and both dorsal pedal and posterior tibial arteries were

palpable. In spite of this man's age and x-ray evidence of calcified vessels, the predominating factor in this case was evidently vasospasm, which responded to treatment with dramatic quickness.

CASE 2.—J. B., a machinist, aged 70, had always been in excellent health until his present illness, which began three years previously with the symptom of intermittent claudication if he walked more than one block. This increased in severity. Two years later he began to have cramps in his calves at night. Three months before admission a dark spot appeared on the medial side of the left great toe and another over the lateral aspect of the same foot. These increased in size and the foot became painful and swollen. Both feet were cold and the left, when dependent, was a purplish red. He was admitted to the surgical pavilion. The popliteal and dorsal pedal arteries were not palpable, Buerger's sign was positive and the oscillometric readings (table 13) were markedly diminished. There was an area of dry gangrene extending from the base of the nail of the left great toe to its distal end under the nail, 2.5 by 2 cm. in diameter. There was another gangrenous area about 2 cm. in diameter over the prominence of the cuboid bone. The urine showed albumin, casts and sugar. The blood sugar was 0.221 Gm. per hundred cubic centimeters (normal, 0.07 to 0.09). The dismissal note from the surgical pavilion read "Patient has been treated with alcohol dressings, heat and negative pressure without change in local lesions. Diabetes controlled with diet and small doses of insulin. Patient advised to have amputation of left leg. Patient refused." He was then referred to the clinic for peripheral vascular diseases. He was given the dietary regimen (with only 1½ pints of milk), 2.5 Gm. of calcium lactate and the exercises. He also received sodium citrate by vein, 150 cc. in the first injection and thereafter 250 cc. every day and then every second day until he had

had fifty-six injections. After the second injection he was able to sleep at night without pain. Until then he had been kept awake with pain, sedatives giving him only short relief. After the sixth injection his foot was definitely improved. After the nineteenth injection the lesions were dry, shrunken and well demarcated. Healing was complete in four months. The patient now walks without discomfort if he walks slowly.

CASE 3.—E. M., a housewife, aged 53, had had for five years a dull ache in the left foot, which became worse on walking. The pain was not entirely relieved by rest and frequently spread

upward, involving the leg and thigh. She complained of numbness and tingling in the hands, and both feet and hands became blue in the cold.

At the age of 12 years she had received buckshot wounds in the popliteal space of both legs. For many years she had suffered from peptic ulcer, varicose veins and constipation. For four years she had known that her blood pressure was high. Her treatment had consisted of diet for the peptic ulcer, phenobarbital for nervousness and high blood pressure, epsom salt for constipation, and massage and baking of both upper and lower extremities.

Examination on admission to the clinic showed extremities that were normal in color but cold even though the day was warm. There were a few tender spots along the muscles of the leg and about the ankles. Pulsations of the dorsal pedal arteries were palpable but faint. The oscillometric readings (table 14) were diminished. The nails showed trophic changes. The skin was dry. The blood chemistry and urine were normal. The blood pressure was 220 systolic, 106 diastolic. The blood viscosity was 6.5. X-ray films of the extremities showed multiple small foreign bodies of metallic density in the region of both knee joints. The report stated that they were probably gun shot. The vessels of both legs were calcified. Treatment in the clinic consisted of the dietary regimen, exercises and soaks, and sodium citrate by mouth. There was no improvement after three weeks of this schedule. Sodium citrate was then given by vein. After ten injections there was complete

relief of pain in the legs, her hands and feet were less cold, and the numbness had disappeared. She had no digestive discomfort, and the bowels were regular with lactose. The blood pressure was 150 systolic, 110 diastolic. The blood viscosity was 5.2. She has required no further injections and is doing well on the dietary regimen and Buerger's exercises.

CASE 4.—B. R., a Russian Jewish merchant, aged 62, had severe pain in the left foot and great toe of one week's duration. For one and one-half years he had intermittent claudication and pain in the left foot on walking one block. He had worried considerably about his health and financial condition during this time; otherwise his past history was negative. Examination showed cyanosis of the left great toe, slow capillary return, trophic changes in the nails, a positive Buerger's sign, reduced oscillometric readings (table 15) in both lower extremities, and dermatophytosis of the feet. The blood pressure was 170 systolic, 100 diastolic, and the blood sugar was 0.107 Gm. per hundred cubic centimeters. The patient improved slowly but steadily on oral treatment, the severe pain in the foot disappeared and the color improved. After three months he could walk three blocks instead of one block without pain. After two additional

months there was no further improvement. He was then given sodium citrate intravenously. He had forty-six injections during the next two months and improved so that he could walk indefinite distances at a slow pace. Several months after injections were discontinued he again had pain on walking a few blocks. He was again given ten injections of sodium citrate, again felt better and could walk comfortably; he was not seen for two months, when he stated that on some days he could walk well while on others he could not walk more than a block without pain. He was then given ten injections of calcium gluconate (10 cc. of 20 per cent solution) and again improved.

In this case the injections of citrate were followed by increased circulation in the extremities as evidenced by improvement in symptoms and oscillometric readings, but the vasospastic element, apparently considerably influenced by worry on the part of the patient, was not controlled by the dietary regimen alone. About a year after treatment was started, during a period in which he did not receive any injections, his symptoms and oscillometric readings again became worse and were again improved, this time after injections of calcium by vein.

CASE 5.—This is a case of thrombo-angiitis obliterans in a woman, a heavy smoker. L. S., aged 36, had an ulcer on the dorsum of the left foot with severe pain, of four months' duration. Three years before admission she had had "neuritic" pains in both arms for which the etiology was not determined. Six months before admission similar pains developed in the left leg and foot and two months later an ulcer appeared at the base of the left great toe. Treatment previous to admission

consisted of rest in bed for about three months, baking, massage and finally local injection around the ulcer (substance unknown) and sedatives for pain. Examination on admission showed an ulcerated area about 4 cm. in diameter on the dorsum of the left foot at the base of the great toe. The tendons and deep structures were exposed, and there was no evidence of granulation. The surrounding skin was a dark bluish red and slightly edematous. The entire foot was cyanotic and cold. The dorsal pedal pulse was not palpable. The right foot was normal in appearance. Both hands showed patchy, erythematous mottling on the thenar and hypothenar eminences. The nails were thickened and there was some atrophy of the finger tips. The radial pulse was not felt on the left but was palpable on the right. Other observations were negative except for moderate obesity. The blood chemistry and basal metabolism were normal. X-ray examination failed to show any local bony changes but did show spotty decalcification throughout the entire foot. Oscillometric readings (table 16) were decreased throughout. Treatment consisted of rest in bed and daily injections of 250 cc. of sodium citrate in addition to the dietary regimen, sedatives and warm soaks. She improved slowly but steadily and was discharged on the ninety-first day after admission with the ulcer markedly reduced in size and nearly healed. At home she did her housework and stated that she did not resume smoking. For two months she was free of symptoms, but the ulcer did not heal entirely. She began to have pain again and the ulcer increased in size. She was readmitted to the hospital. The ulcer measured 1 by 2 cm., and the base was covered with granulation tissue over which was a thin layer of purulent exudate. Treatment was resumed and, when the ulcer was clean, skin grafts were applied but sloughed off, and amputation of the great toe became necessary. The wound was left open and moist dressings were applied. The wound healed slowly and the patient was discharged from the hospital

on the eighty-seventh day. In fourteen months she has had no further trouble; both upper and lower extremities are normal in color, the left radial pulse is palpable, and she is free from pain.

CASE 6.—A. A., a man, aged 35, an American, a bartender, strong and healthy, a heavy smoker, had been on a diet deficient in calcium. His past history was otherwise negative until nine months before admission when he bruised the second and third toes of the right foot. Two months after this injury the two toes were amputated. The stumps did not heal. He was then admitted to the New York Hospital, where with rest in bed, heat and soaks, healing proceeded very slowly. Healing was markedly speeded up when sodium citrate was given by vein. Examination on admission showed ulceration of the bases of all the toes of the right foot. The remaining three toes were cyanotic and cold. No pulsation of the dorsal artery was felt on the right, while there was a faint pulsation on the left. Oscillometric readings (table 17) were reduced in both extremities. The blood pressure was 120 systolic, 90 diastolic. The blood calcium was 10.8 mg. per hundred cubic centimeters, the blood phosphorus 2.2 mg. and the blood viscosity 7.5. With daily injections of sodium citrate, healing took place in one month. The blood viscosity was reduced to 5.5 and the oscillometric readings were improved. After leaving the hospital he went back to his previous way of living; he resumed smoking and did not follow the dietary schedule. Six months later he returned to the hospital with ulceration of the left great toe. The blood viscosity was again high, 7.2, and the oscillometric readings were again reduced. He was treated in the clinic with another course of injections of sodium citrate. At first injections were given daily, then three times a week until healing occurred. He has since adhered to his diet, does not smoke and was free of symptoms until he lost his job and became much worried. He again had pain on walking a short distance, whereas after his last course of treatment he had walked several miles without pain. Subsequently, although still without work, he had ceased to fret so much about his ill luck, is free from symptoms, and the oscillometric readings, though not so good as before, are improved over those taken during the period of his greatest anxiety.

COMMENT

Since 1913, when Koga³ in Japan used hypodermoclyses of Ringer's solution to reduce the viscosity of the blood, which he and Mayesima⁴ had found to be high in thrombo-angiitis obliterans, several different medical methods have been used in the treatment of this disease. These methods have aimed to correct abnormal changes in the blood, to increase the blood volume, or to produce peripheral dilatation in other ways. A review of the various treatments is given in a Mayo Clinic monograph⁵ on thrombo-angiitis obliterans.

In a study of thirty-two cases of thrombo-angiitis obliterans in the First Medical Division of the old New York Hospital, we found a high blood calcium in twenty-nine and a low blood phosphorus (inorganic) in twenty-five. The calcium ranged from 11.6 to 14 mg. per hundred cubic centimeters, the average being 12.2 mg. The phosphorus ranged from 2.2 to 3 mg. per hundred cubic centimeters, the average being 2.5 mg. Silbert,⁶ in a series of forty cases likewise found a hypercalcemia, the average in his cases being 12.4 mg. A retention of calcium also was found in five of our cases in which calcium balance studies were carried out. We were interested to see whether decrease of the high calcium content of the blood and increase

in the excretion of calcium would favorably influence the course of the disease. To increase the excretion of calcium we used sodium acid phosphate and sodium citrate. The latter also reduces the viscosity of the blood. We also prescribed a diet low in calcium. On this regimen the calcium content of the blood and calcium excretion became normal, and the viscosity of the blood, high in those cases in which it was determined, was reduced. Symptoms were improved in most of the cases.

In our present group of fifty-four cases of thrombo-angiitis obliterans, while a low blood phosphorus was found in about 78 per cent—as in the former group—a high blood calcium was found in only three cases. No calcium balance studies have been done in the second group. More investigation is necessary before the nature of these observations can be properly evaluated.

In the second group of cases we substituted a high calcium intake for the low one, not only because the blood calcium was not high but because, no matter what the form of disturbance in calcium metabolism might be, it is doubtful whether a calcium intake less than that required for positive calcium balance is ever indicated as a form of therapy for any considerable length of time. The effect of sodium citrate is the same whether the intake of calcium is high or low.

With the use of the high calcium regimen and sodium citrate not only have the clinical results in thrombo-angiitis obliterans been more satisfactory and long lasting than with the low calcium intake but the results in cases of arteriosclerosis have been even better. Reports in the literature show that other medical methods, such as injection of foreign protein and hypertonic sodium chloride solution, have also been successful in the treatment of thrombo-angiitis obliterans, but we have failed to find any reports of similarly good results in the treatment of a series of cases of arteriosclerosis.

The use of sodium citrate is not attended by any ill effects, such as may follow foreign protein therapy and hypertonic sodium chloride injections. Because it increases the excretion of calcium, its prolonged use may result in a deficiency in calcium unless the intake of calcium is adequate. Accordingly, in the long run, the effects of sodium citrate are better when the intake of calcium is high.

A high calcium intake, besides preventing calcium depletion of the body through sodium citrate, exerts an antivasospastic influence and, as Sherman⁷ has observed, also produces a beneficial effect on general health. It apparently does not affect the viscosity of the blood adversely, nor does it, as some fear, lead to increased arteriosclerosis.

SUMMARY

1. A rationale of treatment of arteriosclerosis and thrombo-angiitis obliterans is as follows: (1) no tobacco, (2) diet high in calcium and vitamins, (3) the use of sodium citrate in the severe cases, and (4) proper care of the extremities.

2. Of ninety-nine cases of arteriosclerosis, 83.8 per cent showed improvement; of fifty-four cases of thrombo-angiitis obliterans, 79.6 per cent showed improvement.

3. The results show that arteriosclerosis is as amenable to this type of treatment as is thrombo-angiitis obliterans.

DINITROPHENOL AND DESICCATED THYROID IN THE TREATMENT OF OBESITY

A COMPREHENSIVE CLINICAL AND LABORATORY STUDY

SAMUEL SIMKINS, M.D.

PHILADELPHIA

Within the last three years, dinitrophenol burst upon the medical world with meteoric suddenness. The groundwork was laid as early as 1885,¹ when the effects, on the dog, of dinitro-alpha-naphthol (a compound closely related to dinitrophenol) were studied. Interest in the drug lapsed until the World War, when poisoning of those working with it in munition plants was frequent.² Since 1933,³ when its possibilities, especially in the treatment of obesity, were first spread before physicians, the drug has enjoyed a phenomenal growth in usage. Recently, Tainter⁴ has given as an estimate that 100,000 patients are taking, or have taken, dinitrophenol.

A detailed study of the voluminous literature on dinitrophenol reveals surprising gaps in our knowledge of the drug. Although our knowledge of the pharmacology and clinical actions of the drug rests on a secure footing, studies of its clinical pathology are woefully inadequate. Accordingly, this paper presents clinical and laboratory studies on a group of 159 ambulatory obese patients who were selected at random and treated with dinitrophenol.

PHARMACOLOGIC ACTIONS

The basic action is an acceleration of tissue metabolism. The pharmacologic actions are similar in animals and in men.⁵ The earliest detectable effect of dinitrophenol administration is an increase in the basal metabolic rate. A single oral dose of from 3 to 5 mg. per kilogram of body weight produces an increase in the basal metabolic rate of from 20 to 30 per cent within the first hour. This level is maintained for twenty-four hours and then falls gradually to normal on the third day.⁶ With daily administration there is a rapid rise of the basal metabolic rate on the first day, a slight additional rise on subsequent days, and the maximum on the fourth day. This is in marked contrast with the slow incidence and subsidence of thyroid action. After the dinitrophenol is discontinued, the basal metabolic rate falls to normal within three to fourteen days.⁷ The response to a given dose may vary considerably from day to day.⁸ If the basal metabolic rate rises less than 30% or 40 per cent¹⁰ there is little reaction except peripheral vasodilatation, and a slight increase in respiratory minute-volume. A greater elevation produces uncomfortable heat and sweating. Larger doses may

cause a metabolic rise ten times the normal,¹¹ a rise in metabolism so rapid and extreme that heat production outstrips heat dissipation and the subject may die of hyperthermia.

The fever is a consequence of, rather than the cause of, the metabolic rise.¹² The hyperthermia is not of central origin.¹³ It is due to direct stimulation of cellular respiration.¹⁴ The hyperthermia and rise of metabolism are not related to the glutathione content of the tissues, which is considerably reduced.¹⁵ The hypothesis is held quite generally that dinitrophenol, like glutathione, is a respiratory ferment.¹⁶ Metabolic increases have been obtained in various preparations of isolated tissues perfused with suitable concentrations of dinitrophenol.¹⁷ If increasing doses are given, a fairly constant relationship between the size of the dose and the degree of fever is noted. If the drug is administered repeatedly, at intervals of three or more days, no development of tolerance is noted.¹⁸ On the other hand, tolerance is induced toward fatal doses if administered at twenty-four hour intervals.¹⁹ The rate of renal excretion plays an important rôle in determining the total response to dinitrophenol.²⁰

The respiratory quotient shows a considerable fall during dinitrophenol medication,²¹ in sharp contrast with thyroid, which produces no significant variation. The extra energy of metabolism is derived mainly from fat²² and practically not at all from protein or carbohydrate. Consequently, dinitrophenol in therapeutic dosage produces no breakdown of significant amounts of body protein, even with patients on an inadequate protein intake.²³ This is in marked contrast with the very considerable increase in nitrogen excretion observed in patients undergoing treatment with thyroid.⁹ The fat used is completely and satisfactorily broken down, as no ketone bodies are found in the urine.²⁴ There is no hyperlipemia or consistent change in the fixed and fatty acids of the blood.²⁵

Dinitrophenol effects a marked acceleration of tissue metabolism, resulting in a marked increase of oxygen consumption and hyperventilation. The serum pH remains within normal limits, the bicarbonate concen-

The laboratory studies were performed chiefly in patients drawn from Dr. Mitchell Bernstein's medical outpatient department at the Jewish Hospital.

tration decreases, and the chlorides increase²⁶ or remain unchanged.²⁷ Reports tend to show a marked creatinuria and increased excretion of creatine, as well as an increased fecal excretion of calcium.²⁸ In this respect dinitrophenol is similar in its effects to desiccated thyroid or thyroxine. There are no significant changes in blood calcium, blood phosphorus or nitrogen balance.²⁹

In strong contrast with thyroxine, dinitrophenol has no effect on hypothyroidism, even when the patient responds with an increase in metabolism. The symptoms of myxedema are unalleviated.³⁰ Dinitrophenol lacks the power of thyroxine to accelerate developmental processes.³¹ Apparently the effect of thyroxine on the metamorphosis of tadpoles is not a direct result of the increased metabolism but presumably an independent action.

In the body, after reaching the blood, or even before, dinitrophenol undergoes certain chemical changes into reduction derivatives, which are of varying complexity.³² Of these the most important is amino-2 nitro-4 phenol, which is found in great abundance in the urine of seriously intoxicated patients and consequently is used as the basis of the Derrien test.³³ The infallibility of this test, which is cited repeatedly in the literature to prove the presence of dinitrophenol poisoning, has been exploded by Bolliger.³³

ADMINISTRATION OF DINITROPHENOL AND METHODS OF STUDY

The series studied comprised a total of 181 unselected ambulatory obese patients, of whom 159 were given dinitrophenol exclusively or in combination with desiccated thyroid. The effects of diet, combined with desiccated thyroid, were studied in the other twenty-two patients. The patients included three with chronic arthritis, five with syphilis (of whom one had tabes dorsalis), twelve with hypertension (of whom two had advanced chronic nephritis) and four with moderately advanced rheumatic heart disease (of whom two had mitral stenosis). The method employed consisted of the administration of one capsule (100 mg. of sodium dinitrophenol) the first day, two capsules the second day and three capsules daily thereafter (preferably after meals). At the end of one week the patient was reexamined. Thereafter the dose was regulated as was found necessary. Patients were warned to discontinue the drug if marked itching or a skin rash appeared. No attempt at rigid dietary control was made. The patients were merely given general dietary instructions.

Basal metabolism studies were performed in sixty-six cases. Liver function was tested by the determination of the icteric index after the serum was decolorized with dilute hydrochloric acid, by the van den Bergh reaction on the serum, and by the bromsulfalein test (intravenous use of 2 mg. of the dye per kilogram of body weight). Renal function was tested by repeated urine examinations and by the use of the intravenous phenol-

sulfonphthalein test. Effects on the circulatory system were studied by examination of the pulse, blood pressure and electrocardiographic tracings. Carbohydrate metabolism was studied by means of the fasting blood sugar and the dextrose tolerance test (175 Gm. of dextrose orally per kilogram of body weight).

CLINICAL ACTIONS

The chief clinical effects of therapeutically effective doses of dinitrophenol are those of increased heat production. The patient becomes conscious of a sensation of warmth, together with an increase of perspiration. These sensations may be so extreme as to make the patient acutely uncomfortable. A few do not perspire at all. In others, drenching sweats occur, usually at night. In the majority the sweating is generalized. In a considerable minority, the sweating is localized to the physiologic area from the neck upward. Only two patients complained of some dyspnea on exertion, "due presumably to an increased need for oxygen."³⁴ The majority felt a tremendous improvement in their sense of well being. The temperature, pulse rate and respiration were carefully watched. It was found that the temperature is an excellent guide of impending toxicity. The rule was followed invariably that, when the temperature rose as high as 99.2 F., the drug was either discontinued or the dosage sharply reduced. In this way, many impending reactions were avoided. The temperature usually remained well within normal limits. It was not unusual for the respirations to be increased by as much as ten per minute. The respiratory rate is not a sensitive guide to toxicity. The pulse, as described elsewhere, showed no significant alterations in most patients.

Tolerance to the drug is established rapidly, so that to produce a consistent loss of weight the dosage must gradually be raised. On the other hand, the acquired tolerance is rapidly lost if the drug is discontinued for as short a period as two weeks. The dinitrophenol may then be resumed at a lower dosage level with its original effect on the patient. It is remarkable how sensitive many patients are to a slight increase in the dosage.

It is not unusual for a patient to cease losing weight suddenly after weeks of steady, satisfactory weight loss. Apparently two factors are chiefly concerned. Concrete examples will suffice:

Factor 1 is rapidly acquired tolerance to the drug. Thus, one patient, on a daily dose of 5 grains (0.32 Gm.), resulting in a metabolic rate of +26 per cent, lost weight at an average rate of 3 pounds (1.4 Kg.) a week for seven weeks. Then, for six weeks, she lost no weight even though the dose was raised to 6 grains (0.4 Gm.) daily. A basal metabolic rate determination at this time was found to be +6 per cent.

Factor 2 is by far the more important one. Apparently dinitrophenol has a tendency to promote storage of water in the body. For example, a patient on a daily average dosage of 4½ grains (0.3 Gm.), with a basal metabolic rate of +46 per cent, lost an average of 2 pounds (0.9 Kg.) a week for eight weeks. Then she suddenly stopped losing weight. The dosage was increased to 6 grains (0.4 Gm.) daily for four weeks, with no resultant weight loss. A basal metabolic rate determination at this time was +62 per cent. Presumably, the effect of the heightened metabolism was masked by the accumulation of water in the tissues. In such cases, merely discontinuing the drug temporar-

ily often results in a rapid loss of weight. The drug can then be resumed with its former effectiveness.

In a few patients the water-logging of the tissues becomes so pronounced that frank edema, most evident at the ankles, may result. Careful study of such patients discloses no etiology other than the direct action of the dinitrophenol. Occasionally spectacular results may be obtained by the intravenous use of salyrgan.³⁵ In one

A very interesting phenomenon is observed with the change of seasons. As summer passes into fall, it is found that the patient suddenly ceases to lose weight, although the weight loss before may have been very satisfactory and steady. That the mechanism involved is not the development of tolerance is attested by the fact that a considerable group of patients exhibit this phenomenon simultaneously. In the case of dinitrophenol it may be partly accounted for, but only partly, by the diminution of sweating that accompanies the colder weather. In the hot summer months, small doses of dinitrophenol will produce a weight loss that will be matched in the cold winter months only by considerably larger doses. Such loss of the calorigenic power of certain drugs at low temperatures has been known for some time.³⁷ The proved capacity of low temperatures to abolish and even reverse the calorigenic action of certain substances (endogenous and exogenous in type) has no adequate explanation.

LIVER FUNCTION

It is easily conceivable why dinitrophenol should be suspected of being toxic to the liver. It is closely related chemically to trinitrophenol (picric acid) and other compounds that are liver poisons. Animal experiments in general show no toxic effects on the liver.³⁸ Post-mortem studies of these animals showed no significant damage to the liver following repeated medication with nonfatal, fever-producing doses and with doses ultimately becoming fatal.³⁹ In human beings the reports are rather meager, but they bear out the view that dinitrophenol is not a hepatotoxin, except in isolated instances.⁴⁰ Two cases of poisoning with fatal termination showed moderate congestion, a slight detachment of hepatic cells from one another, and slight fatty infiltration in the periphery of the lobules.⁴¹

Dinitrophenol often discolors the sclerae and even the skin, thus producing the clinical appearance of jaundice.⁴² This occurred, in a marked degree, in seven cases of the present series. The discoloration varies considerably from time to time and usually disappears gradually, even though the medication is continued. To avoid error in the determination of the icteric index, the blood plasma must be acidified.

Tainter, Cutting and Stockton⁴³ reported a series of cases in which icteric index and van den Bergh studies were done (table 1). Their results show no liver damage. In the present series, fifteen patients were carefully studied with the icteric index, van den Bergh and bromsulfalein tests. A study of table 1 discloses no liver damage even after months of intensive medication. If liver damage was present, one would expect the blood

* Two patients showed values over 0.5 mg. but there was no demonstrable clinical evidence of liver damage.
† One patient, at the end of four weeks' medication, had an icteric index of 20, direct delayed weakly positive van den Bergh reaction and indirect van den Bergh reaction of 0.25 mg. At eighteen weeks and at twenty weeks, all tests gave normal values.

patient, for example, two injections resulted in a loss of 12½ pounds (5.6 Kg.) in one week.

Rapid, large weight changes are very common. They are due chiefly to alterations in the water content of the body. For this reason many patients lose 5 pounds (2.3 Kg.) or more during the first week. The loss of weight often assumes a steplike pattern. "A gain of weight may occur while the body tissue is being consumed, solely because water is being added to the body, and weight may diminish in the face of overfeeding, because depletion of water is also taking place."³⁶

bilirubin to increase in proportion to the amount of drug ingested. No such relationship is observed. One patient developed, in the fourth week of medication, an icteric index of 20 and a weakly positive, direct, delayed van den Bergh reaction. The bromsulfalein test was negative. Complete studies at eighteen and at twenty weeks in this case revealed no liver damage. Another patient took the drug almost continuously for eighty-one weeks (consuming a total of 245 Gm.) and showed no liver damage.

The question of delayed liver damage has been inadequately studied. The only report in the literature⁴³ is one that deals with six patients who showed an average bilirubin count of 0.24 units (0.15-0.40) after the drug had been discontinued for thirty-six weeks.

In conclusion, it seems quite justifiable to state that dinitrophenol, in therapeutic dosage, is not a hepatotoxin, except in the extremely rare case in which there may exist an idiosyncrasy that may mediate damage to the liver.

KIDNEY FUNCTION

Experimental studies on animals show no toxic effects on the kidney.⁴⁴ Postmortem examination of the kidneys in these and in other animals dead of dinitrophenol poisoning⁴⁵ revealed no significant pathologic changes grossly or microscopically, except mild degrees of cytolysis. Clinical reports on human beings are scattered and in the main bear out the view that dinitrophenol is nontoxic to the kidneys.⁴⁶

Thirty-three intravenous phenolsulfonphthalein tests were performed on fifteen patients. It must be remembered that this test, which is the most widely used of the renal function tests in this country, is subject to wide clinical aberrations.⁴⁷ Half the normal renal tissue can be removed without influence on results of the test, so that normal excretion of the dye does not necessarily indicate unimpaired renal function. With these limitations in mind, examination of table 2 reveals no significant impairment of renal efficiency.

Repeated urine examinations were made of these fifteen as well as of five other patients. In nine, no urinary changes occurred. In five a previous albuminuria disappeared or became greatly decreased in amount; in two of the five, casts disappeared. In six patients, who had negative urinalyses at the beginning, a slight albuminuria developed: in four, as medication was continued, the albuminuria disappeared; in the other two it persisted. In short, "It is unlikely that dinitrophenol in ordinary clinical dosage will injure the kidneys."⁴⁸

CARDIOVASCULAR SYSTEM

Dinitrophenol is remarkable for its lack of significant effects on the cardiovascular system even when the basal metabolic rate is raised to high levels. There is no significant change in the pulse rate.⁴⁹ In this respect

(the absence of relationship between the pulse rate and the basal metabolic rate) dinitrophenol differs from other known accelerators of metabolism. Of a group of eighteen psychotic patients, five showed toxic effects characterized by tachycardia, a fall of blood pressure, and stupor.⁵⁰ No similar reports have appeared in the literature on psychotic⁵¹ or nonpsychotic patients.⁵² In the present series only one (who became toxic) developed tachycardia. Otherwise the patients showed no significant change in pulse rate.

Many investigators in small series of cases, found no change in blood pressure.⁵² Others found a marked difference in the response of hypertensive and nonhypertensive patients. "In patients with normal blood

pressure no important change in either systolic or diastolic pressure or in pulse rate has been demonstrated."⁵³ Hypertensive patients showed a definite fall of both systolic and diastolic pressures; hypotensive patients showed little or no further decrease of blood pressure.⁵⁴ Tainter, Stockton and Cutting⁵¹ concluded that such changes in blood pressure as occur are probably due to loss of body weight.

In the present series (181 patients) were twelve hypertensive patients (ten female and two male), of whom ten were placed on dinitrophenol medication. Seven were so-called essential hypertensives, two had chronic nephritis with hypertension dating from neph-

ritic toxemias of pregnancy, and one had a malignant hypertension. In all ten, striking amelioration of the hypertension resulted very rapidly. The blood pressures dropped sharply within one to five weeks. One of the nephritic patients had a drop from 200/156 to 120/80 in three weeks and to 144/88 at the end of two more weeks. Prior to this for eighteen months she had had a hypertension ranging from 180/110 to 230/156, accompanied by severe headaches, dyspnea and dizziness, and irreducible by almost every drug and method in current use for hypertension. She now became asymptomatic for the first time in eighteen months. The blood pressure level stayed down for a few weeks after the dinitrophenol was stopped and then rose again, with a return of the original symptoms. The other nephritic patient's bloodpressure dropped within five weeks from 200/120 to 148/106. In the malignant hypertensive case the pressure fell in one week from 210/120 to 130/100 and at the end of the second week to 130/90.

TABLE 3.—Effects of Dinitrophenol on Electrocardiogram

16	11.0	23.5	Ventricular extrasystoles developed

* Patient with chronic nephritis and hypertension.

In all three cases there was no reduction in weight. Moreover, these three, together with the other seven in the hypertensive series, showed a very rapid fall of blood pressure. Therefore the assumption⁵⁴ that the fall of blood pressure is due to loss of body weight is invalid, and it must be concluded that the hypotensive effect is due to a direct action by the drug on the cardiovascular system.

Typical of the response of the essential hypertensive is one of the patients, a man of 39, who had been a hypertensive since the age of 19 and who had a familial history of hypertension. At the end of two weeks' treatment his blood pressure fell from 166/110 to 148/90 and in one more week to 116/82. In most of the patients the blood pressure rose gradually after the dinitrophenol was stopped, unless there were large, permanent losses of weight.

Bradycardia is an extremely unusual occurrence. It was found in two patients. No similar cases are reported in the literature. In one patient it was associated with latent icterus. The pulse rate dropped steadily from 88 to 56 at the end of four weeks' medication. During the third week the icteric index was 20 and the direct van den Bergh test showed a delayed, weakly positive reaction. The dinitrophenol was not

discontinued and the pulse rate gradually rose to normal within a week and remained normal thereafter. Coincidentally the icteric index and van den Bergh reaction returned to normal. In the second patient the pulse rate fell from 88 to 54 in one week and persisted at this level for a week after the drug was discontinued. Some light may be thrown on this case by the work of Gibbs and Reichert,⁵⁵ who found that the intravenous injection of dinitrophenol in the dog produces a very marked vagal stimulation of a centric nature.

Phlebitis, no reports of which have appeared in the literature as yet, appeared in a woman during the fifteenth week of medication. For three weeks prior to the onset of the phlebitis she had been developing a peripheral neuritis. First discrete, extremely painful, red nodules appeared along the course of the veins of her left leg. Within a few days the condition became more pronounced and a frank phlebitis ensued. Swelling of the leg developed and became marked. The condition subsided within ten days after the discontinuance of the drug.

"Dinitrophenol possesses no power of depleting the heart of its glycogen and . . . in this respect it differs from thyroxine. . . . In acute poisoning, dinitrophenol causes a marked reduction of liver and muscle glycogen but affects only slightly or not at all the heart glycogen, unless anoxemia supervenes. . . . In chronic dinitrophenol poisoning the glycogen reserves of the heart, liver and muscle are at normal levels within four hours after the last injection."⁵⁶

ELECTROCARDIOGRAPHIC CHANGES

It is really amazing in view of the widespread use of, and interest in, dinitrophenol that electrocardiographic studies are so meager. Tracings in rabbits⁵⁶ and in cats⁵⁷ showed moderate changes. Similar changes have been observed in five human beings;⁵⁸ no changes were reported in eleven other subjects.⁵⁹

In the present series electrocardiographic studies were made in sixteen patients on prolonged dinitrophenol medication (table 3). In the majority of patients the drug was given for weeks; in one it was given for eighty-one weeks. In nine patients the electrocardiograms showed no changes. In seven there were changes (in practically all, of a minor character), as listed in the table. As Taussig⁵⁶ states, such changes indicate the development of a "prolongation of the recovery time of the heart muscle together with a decrease in the voltage initiated by ventricular contraction and suggest that some alteration in the metabolism of the myocardium has resulted from dinitrophenol intoxication. . . . There is no evidence that dinitrophenol causes death through a toxic action on the heart."

CARBOHYDRATE METABOLISM

Most reports show that dinitrophenol produces hyperglycemia in animals, the degree of the response being proportional to the dosage employed.⁶⁰ On the other hand, Cutting and Tainter⁶¹ found the blood sugar

been overcome by Himsworth,⁶⁶ who determined that the area enclosed by the blood sugar curve, above the resting level from which it starts, remains constant for the same individual, provided the composition of the diet is maintained constant. Each individual has his own characteristic area for a particular diet. The absolute values of the areas, traced out in different subjects by individual curves obtained on the same diet, vary greatly and are determined by unknown factors peculiar to the individual. For this reason, only curves obtained on the same subject may be compared. Himsworth's method described in 1935 is especially valuable in

D, decreased tolerance; I, increased tolerance; N, no change in tolerance.

67. MacBryde, C. M., and Taussig, B. L.: Functional Changes in Liver, Heart and Muscles, and Loss of Dextrose Tolerance Resulting from Dinitrophenol. *J. A. M. A.* **105**: 13 (July 6) 1935.

Byron.⁶⁸ For example, the accompanying chart shows the graph of patient 6 (table 4 B) in MacBryde and Taussig's series.

Results in Normal Persons.—Of nine patients studied by MacBryde and Taussig (table 4 B), one showed a slightly increased tolerance, two practically no change, and six definitely decreased sugar tolerance (of whom four were very marked). The fasting blood sugar showed no significant change. MacBryde and Taussig⁶⁷ report that "the loss of tolerance was evident after seven days and increased in degree with the duration of administration and with the total dose given. . . . No patient showed an increased ability to utilize dextrose." This conclusion is unjustified, as a study of the

ance and one a decreased tolerance. In the remaining three patients of the series (11, 12 and 13), unfortunately no control curves were made. Whether their tolerance remained unchanged, increased or decreased it is impossible to state. But a study of the curves according to conventional methods reveals, at the least, a normal or increased sugar tolerance. There was no significant change in the level of the fasting blood sugar in the series.

Results in Patients with Diabetes Mellitus.—The prevailing opinion holds that the carbohydrate tolerance of diabetic patients is depressed by all measures except moderate exercise, which stimulate the general metabolism.⁶⁹ No method of comparing diabetic curves has

tolerance areas shows. Thus, patient 9 shows no greater degree of loss of sugar tolerance than does patient 3. Wishnofsky and his co-workers⁶⁸ studied ten normal patients. Inspection of table 4 C shows that the fasting blood sugar level was raised significantly above the control fasting blood sugar level, but with no development of hyperglycemia. Of the ten patients, seven showed a decreased sugar tolerance, only three being marked. On the other hand, three showed an increased tolerance. In the present series (table 4 A), thirteen patients were studied. Ten had control dextrose curves. Seven of the ten showed striking increases in dextrose tolerance, the changes being so marked that there can be no question of interpretation; two showed no change in toler-

ance. One must rely, therefore, on the level of the fasting blood sugar and the peak attained. In three diabetic patients (table 5 B), MacBryde and Taussig⁶⁷ found an impaired tolerance, although inspection of the table shows the impairment to be moderate. Wishnofsky and his co-workers,⁶⁸ using a statistical method of analysis⁷⁰ in a series of eleven cases of mild and moderately severe diabetes and nine cases of severe diabetes (table 5 C), concluded that there was no significant change in the mean values of the fasting blood sugar or dextrose tolerance curves before and after the administration of dinitrophenol. This was true regardless of the severity of the diabetes. Inspection of table

69. Dinitrophenol Contraindicated in Diabetes, Queries and Minor Notes, J. A. M. A. 102: 2135 (June 23) 1934.
70. Fisher, R. A.: Statistical Methods for Research Workers, ed. J. London, Oliver and Boyd, 1930, p. 104.

5 C shows that of the eleven patients in the mild and moderately severe group five showed an increased tolerance, one no change, and five a decreased tolerance. In the group of cases of severe diabetes, five showed an increased tolerance (two being marked), two no change, and two a decreased tolerance. The level of the fasting blood sugar paralleled the change in dextrose tolerance. In the present series (table 5 A) there were four cases of prediabetes and five of moderately severe diabetes. Studies in one case of prediabetes and four cases of diabetes showed an increased tolerance with a significant, though moderate, decrease in fasting blood sugar.

These three sets of studies are far from agreeing. The only difference is that the studies of MacBryde and Taussig, and those of Wishnofsky and his co-workers, were carried out for short periods of time only (from seven to twenty-eight days). Mine were carried out with fairly prolonged dinitrophenol administration (from twenty-one to 420 days). It is interesting in this connection to note that in patient 1 of the present series (table 4 A), in whom the drug was used only five days, a decreased tolerance was found, in agreement with the results of MacBryde and Taussig and of Wishnofsky and his co-workers. Apparently the conclusions to be drawn are that, with short courses of dinitrophenol administration in normal individuals, there is moderate elevation of the fasting blood sugar level (though not hyperglycemia) and a moderate impairment of carbohydrate tolerance, in the majority of cases. With prolonged administration there is no change in the fasting blood sugar and a marked increase of carbohydrate tolerance. In diabetic patients, on short courses of dinitrophenol administration, the results are variable, the dextrose tolerance being apparently increased as often as decreased with parallel changes in the fasting blood sugar. With prolonged administration in cases of diabetes there is apparently an increase of carbohydrate tolerance. The bearing of these results on possible application in the field of diabetes mellitus is self evident. In no case of the three series reported (a total of thirty-two cases of diabetes) was there any evidence of toxicity. This lack of increased toxicity is in startling contrast to the currently held view.⁶⁹

GASTRO-INTESTINAL TRACT

Gastro-intestinal complaints occupy only a minor field in dinitrophenol therapy. Cases of severe gastro-enteritis, anorexia and vomiting are uncommon.⁷¹ In the chronic intoxication of munition workers, the French writers⁷² reported anorexia, nausea, vomiting, diarrhea and abdominal pain. In the present series, gastro-intestinal complaints were few and minor. In three cases transient diarrhea developed. An occasional patient vomited at times after swallowing a capsule, evidently on account of gastric irritation. More troublesome was the development of severe "heartburn" in four patients, which was readily controlled by sodium bicarbonate. In general, the clinical effects of dinitrophenol on the gastro-intestinal tract are negligible, except in chronic intoxication.

METABOLIC LEVELS AND BLOOD CHOLESTEROL

Writers are in general accord⁷³ that the basal metabolic rate in obesity is usually normal. "In a fairly high

percentage of obese patients, we have found the inconsistent finding of an increase in the metabolic rate. I find that other investigators have found the same thing."⁷⁴ There is little relation between the basal metabolic rate and the degree of obesity.⁷⁵ The foregoing statements are substantiated by the results of Tainter, Stockton and Cutting³⁴ and my results (table 6). The average increase in the basal metabolic rate is roughly 11 per cent for each 0.1 Gm. of the daily dose of dinitrophenol (table 6). Variations in individual patients are marked, however. "Unlike thyroxine, dinitrophenol appears to have about the same effect on metabolism, regardless of the level before treatment . . . an absence of the initial period of intoxication, that follows the administration of thyroxine."⁷⁶

Tolerance is built up rapidly, so that it requires a higher dosage to produce a like increment of basal metabolic rate in a given patient as the drug is administered continuously. It is not unusual for some patients to fail to respond to the highest therapeutic doses with an increase of the basal metabolic rate or loss of weight. In other patients no weight is lost, even though the basal metabolic rate is raised to exceedingly high levels.

Dextrose tolerance curve areas: ordinate, blood sugar in milligrams per hundred cubic centimeters; abscissa, time of dextrose tolerance test in minutes.

In thyroid disease there is a striking inverse relationship between the level of the basal metabolic rate and the blood cholesterol concentration.⁷⁷ This relationship does not hold between dinitrophenol and blood cholesterol. Consequently the changes in blood cholesterol present in thyroid disease are not related directly to the metabolic rate but to other actions of the thyroid secretion.⁷⁸ The reports on blood cholesterol fluctuation in dinitrophenol therapy are very few and are somewhat conflicting.⁷⁹ In a group of thirteen excellently controlled patients, Grant and Schube⁸⁰ found in most an initial elevation of blood cholesterol, then a drop below the original level, followed by a gradual return to "normal." In the present series, blood cholesterol determinations were followed in five cases. No consistent results were obtained.

Clinical Notes, Suggestions and New Instruments

TULAREMIA FROM THE BITE OF A NURSING KITTEN

C. L. RUESILL, M.D., INDIANAPOLIS

The chief interest in this case is the unusual mode of contagion. A woman, aged 59, owned a female cat that had two nursing kittens. The cat had caught a rabbit and had eaten part of it. Within a few days the cat became ill and the kittens also appeared ill two days later. While trying to feed the kittens, the patient was bitten by one of them on the index finger. Both kittens died the following day but the cat slowly recovered.

The patient had enjoyed good health all her life. Three days following the bite by the kitten, she developed headache, malaise and chilliness. On the fifth day the finger became red, swollen and painful. She had a hard chill and a fever of 103 F. Pain and streaks of erythema extended from the finger to the axilla. Large inflammatory glands appeared on the inner aspect of the arm and in the axilla. The fever abated somewhat after a week but was continuous for a period of four weeks. The patient recovered two months after the onset of the illness. The only relevant laboratory observation consisted of serum agglutination of *Bacterium tularensis*. On the thirteenth day agglutination was complete in a dilution of 1:80 and on the seventeenth day in a dilution of 1:640. The white blood count was slightly increased; the urine was normal.

NEW BONE-HOLDING CLAMP

H. P. RUSH, M.D., SAN ANGELO, TEXAS

Ever since Dr. W. A. Lane introduced the use of metal plates in the open reduction and fixation of fractures there has been some kind of bone clamp used to hold plate and fractured parts in place. This has been done with more or less difficulty and inconvenience to the operator.

I have devised an instrument which I believe is an improvement and which has proved very satisfactory to me. It consists of two long handles with lock effect about 2 inches from the clamp proper. In the upper handle at the distal end it has a bar attached, which has two prongs at the lower portion. The upper portion extends about $2\frac{1}{2}$ to 3 inches upright for the

Bone holding clamp.

purpose of carrying the shuttle. The shuttle carries the upper prong at its lower portion to complete the clamp. The shuttle may have two prongs and is interchangeable. In the lower handle there is placed a threaded bar, which is carried through the upper handle with a thumb tap. The distal ends of the handles are curved in such a manner that it allows easy application without pressure on other tissue and gives it, in a way, a retractor effect. The handles are held apart when not in use with a small spring. It is made in three sizes.

The instrument is easily applied in the transverse manner and in this way does away with the upright handle and allows free use of brace and bit or the screw driver in drilling and applying screws for either bones or metal plates. There is placed in the handle a bar and screw effect which, after the instrument has been applied, may be tightened and the bone and plate held just as snugly and securely as with other bone-holding instruments. Too, it prevents the assistant from being in the way of the operator. By reason of these advantages this instrument, in my judgment, lessens the time of operation considerably, which is advantageous to the patient. The drawing of this instrument illustrates the advantages set forth.

Special Article

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1936

TWENTY-FIFTH ANNUAL REPORT

In preparing this annual review, data have been obtained from the same ninety-three cities which have been referred to in similar articles for the years beginning with 1930. A communication was addressed to the health officer of each city asking that he furnish the number of deaths from typhoid, excluding paratyphoid, for the year 1936. Furthermore, the health officer was asked to designate not only the total number of typhoid deaths but also subdivide these as to resident

*Rate computed from population as of April 1, 1930, as no estimate for July 1, 1933, was made by the Census Bureau.

and nonresident. Special comment was solicited on any unusual outbreak of typhoid that occurred during the year. In each instance (except Scranton, where the figures come from the Pennsylvania State Health Department) the data were supplied by the respective health departments.

As the United States Census Bureau is not prepared to furnish an estimate of population for these cities, the health officer was asked to designate the local estimate which he is using in his statistical compilations. A review of these figures as submitted indicates that they do not vary to any great extent from the 1930 census figures, and if there has been a misjudgment in estimating these population figures the error in the rates is

not significant. In a few instances (as indicated in the footnote of tables 1 to 8) the health department did not furnish a local estimate and the 1930 census figures were used.

As has already been stated, the deaths from paratyphoid have been excluded. A special note has been made in table 9 of cities where all deaths occurred among nonresidents. Another symbol has been used to indicate those cities in which more than one third of the reported deaths were stated to have been among

nonresidents. The need of giving particular heed to this question of residence is well illustrated in the case of Columbus, where the health department reported twelve deaths from typhoid and stated that all were among nonresidents. Fifty-seven cases occurred at the Columbus State Hospital for the Insane and there were nine deaths in this group. The health officer reports that this institution is not under the jurisdiction of the local health department. There were reported thirty-

three deaths in New Orleans and it is stated that twenty-five of these occurred among nonresidents. El Paso reports five out of seven deaths among nonresidents. Houston, with thirteen deaths, has made no separation on the basis of residence.

Six of the large New England cities report no death from typhoid in 1936 (table 1). Bridgeport, Somerville and Springfield report no death for three years in succession. Boston had but one death in 1936 and this is reported as having occurred in a non-resident. The New England cities as a whole (population 2,630,017) again report a new low record of 0.42, which is but 60 per cent of the 1931-1935 quinquennial average.

The Middle Atlantic states have a group rate which is approximately the same as that for the preceding year (0.56 in 1936, 0.55 in 1935). There were no deaths recorded in Utica and Syracuse for 1936, and in Scranton there have been three consecutive years

of more than half a million, all had rates under 1.0, New York for the fifth consecutive year, Philadelphia and Buffalo for the fourth, and Pittsburgh for the second. Yonkers reports seven resident deaths with no comment regarding any special outbreak. The rate for this city of 4.8 is the highest in the group and is equal

to the rate for the same city for the five years 1916 to 1920. This is in striking contrast to the low rate of recent years. Jersey City records two deaths, both in nonresidents, one a resident of Bayonne, the other of Cliffside. Reading, with two resident deaths, reports an outbreak of twenty-one cases (fourteen resident,

seven suburban) traced to a privately owned contaminated well used by a manufacturer in a section of the city recently annexed. Of the thirty-one deaths reported from New York City it is stated that thirty occurred among residents. An outbreak of fifty cases occurred in October 1936, traced to a memorial cake used in a Greek Orthodox Church on September 13.

The South Atlantic cities recorded a marked reduction in the death rate for the group as a whole (1.55 in 1936, 2.58 in 1935). Tampa and Norfolk report no deaths. These cities had the highest rate in the group for 1935, 6.6 and 5.4 respectively. Jacksonville's excellent record of no death in 1935 was spoiled by the reporting of two resident deaths in 1936. Atlanta, which has long had a high rate among the cities of this group, has the highest rate again in 1936, although the rate of 3.2 is significantly lower than that of previous years and quinquennial averages. Of four deaths in Miami, three are recorded among nonresidents. Of the ten deaths in Atlanta, five are reported as nonresident. Being a hospital center for the surrounding area, the ratio of nonresident to total deaths in Atlanta has been high for many years.

In the East North Central group the rate has again increased to approximately the average for the five year period 1931-1935, not as high however as occurred in 1934. There is in the group but one city with a death rate in excess of 2.0 and, as previously indicated, most of these deaths occurred in a hospital in Columbus. While in 1935 there were five cities in this group with no death, there are but three such cities in 1936, South Bend, Evansville and Fort Wayne. Equally impressive

is the reduction in death rate in Evansville (4.7 in 1935, 0.0 in 1936). Nine cases with one death spoiled the admirable record of Grand Rapids, the source of infection being attributed to a bake shop. Cleveland reports that of nine deaths three occurred in the Cleveland State Hospital for the Insane (it should be noted that the health department of Cleveland has included these deaths as residents while in Columbus the health department has recorded nine deaths that occurred in a state hospital for the insane as among nonresidents). Chicago continues to have a very low rate. Milwaukee and Detroit, although low, have not maintained the lower rates of 1935, in which year there was no death recorded in Milwaukee.

The six cities in the East South Central group, while having a lower rate (3.35) than in 1935 (3.94), and lower than the five year average for 1931-1935 (4.81),

Birmingham..... 5.0	New Orleans..... 6.5†	El Paso..... 6.8†

* All typhoid deaths reported were stated to be among nonresidents.
† One third or more of the reported typhoid deaths were stated to be among nonresidents.

continues as a group to rank second only to the West South Central group, which has the highest rate (3.99 in 1936). The actual number of typhoid deaths in this group dropped from forty-nine in 1935 to forty-three in 1936. Chattanooga reported no death. With the exception of Chattanooga and Louisville, all the cities had a death rate in excess of four. Louisville reports that of five deaths two occurred among nonresidents; of thirteen deaths in Birmingham, three were among nonresidents; of seven deaths in Nashville, six were among nonresidents; of thirteen deaths in Memphis, five were among nonresidents. This clearly indicates that the cities in this group are serving as hospital centers for the surrounding areas where typhoid continues to be prevalent. The freedom from typhoid in Chattanooga is in striking contrast to the high death rates of previous years.

The West North Central group reports substantially the same number of deaths in the past two years (twenty-two in 1936, twenty-three in 1935). The rate of 0.79 marks a new low for the group. Minneapolis

and Duluth report no death. After two consecutive years with no death, Wichita reports two resident deaths. Des Moines, with a rate slightly in excess of that in 1935 but materially lower than that of 1934, continues to rank highest.

The eight cities in the West South Central group, after showing a marked improvement in their rate in 1935, have increased their rate slightly in 1936, there being seventy-nine deaths in 1936, seventy-four in 1935. The group rate of 3.99 is the highest for any group but is materially lower than the rate of 5.43 for this group in 1934 and the rate of 5.36 for the quinquennial average of 1931-1935. There were but two cities in this group with a rate less than 2.0 (Tulsa with 0.7 and Dallas 1.5). There were two cities with a rate in excess of 6 (El Paso with 6.8 and New Orleans 6.5). Of the four deaths reported for Dallas, all are stated to have occurred among nonresidents. The high percentage of nonresident deaths in El Paso and New Orleans has already been referred to. No reference is made by the health officer in any instance to an unusual prevalence or outbreak of typhoid. It is quite likely, as in the instance of the East South Central states, that the urban communities provide hospital facilities for

cities with a rate in excess of 5.0, as compared with seven in 1935 and nine in 1934. Comparing the cities by groups (table 12) it will be observed that the high rates are in the Southern states, the medium rates in the Pacific and Northern states, and the lowest rates on the North Atlantic Seaboard and in New England.

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.

† Data for Fort Worth lacking.
‡ The rate for ninety-three cities in 1935 was 1.03 (total population 37,437,812, typhoid deaths 355), whereas in 1930 it was 1.64, and in 1923 and 1924 it was 1.24 and 1.25, respectively. The 1931-1935 average for the ninety-three cities is 1.31.

§ Rate for ninety-three cities in 1936 was 0.96 (total population 38,349,694, typhoid deaths 371).

LOWEST RECORD REACHED

For the seventy-eight cities for which complete data are available since 1910, there occurred 342 deaths from typhoid in 1936, which is the lowest of record (348 in 1935). The rate for this group of cities is for the second consecutive year less than 1.0. The rate for the ninety-three cities studied in 1936 is also slightly

TABLE 10.—Number of Cities with Various Typhoid Death Rates

	No. of Cities	10.0 and Over	5.0 to 9.9	2.0 to 4.9	1.0 to 1.9	0.1 to 0.9	0.0
1906-1910	77	75	2	0	0	0	0
1911-1915	79	58	19	2	0	0	0
1916-1920	84	21	32	30	0	0	0
1921-1925	89	12	17	48	12	0	0
1926-1930	92	3	10	30	37	12	0
1931-1935	93	0	6	17	28	42	0
1936	93	2	6	30	23	22	10
1931	93	2	6	23	28	22	12
1932	93	1	7	13	29	29	14
1933	93	0	7	18	19	34	16
1934	93	0	9	11	27	27	23
1935	93	0	7	15	18	29	24
1936	93	0	3	15	21	36	18

the surrounding areas. Tulsa continues to have the lowest rate in the group, as it has had every year beginning with 1930.

The cities in the Mountain and Pacific states had a reduction in the rate below that of 1935, but not quite as low as 1934. Salt Lake City led the list with no death. There were but two cities with a rate in excess of 1 (San Diego and Denver) and there was no city with a rate in excess of 2. Denver has the unenviable distinction of having the highest rate. Among thirteen deaths occurring in Los Angeles, six were among nonresidents. With two deaths in San Francisco, one was of a nonresident. With this correction for residence, both of the large California cities can boast of an enviable record. Tacoma, after two successive years of freedom from typhoid (the third in its history), reports one resident death.

THE HONOR ROLL

While in 1935 there were twenty-four cities on the honor roll with no deaths from typhoid, there were only eighteen in 1936. Among the cities with a rate from 0.1 to 0.9, the number increased from twenty-nine to thirty-six. This apparently shows the influence of one or two chance deaths from this disease. Bridgeport, Cambridge, Fort Wayne, Scranton, Somerville and Springfield were on the honor roll in both 1935 and 1936.

There were only eighteen cities in 1936 with rates of 2.0 or over, in contrast with twenty-two such cities in 1935 and twenty in 1934. In 1936 there were but three

below 1.0 (0.96). This statistical study shows a downward trend in the death rate from typhoid in the large cities of the United States. As a cause of death this disease is of little consequence in many parts of the country. It is believed that in many urban areas, especially in the South, the prevalence of typhoid in surrounding rural areas materially handicaps the large cities in attaining more promptly a lower death rate from typhoid.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

THE NUTRITIONAL SIGNIFICANCE OF THE CURD TENSION OF MILK

II. The Relation of Curd Tension to the Digestibility of Milk

The early experiments of Brennemann¹ provided a vivid demonstration of the different curd qualities of raw and treated milks. Since that time curd tension has become generally recognized as an important factor in the digestibility of milk in the stomach. It has been thought that the formation of a soft, friable casein clot is advantageous because the digestive juices, which are supposed to act only on the surface of casein particles, could more readily and quickly attack porous or finely divided material. A recent report of the Council² summarized the large number of methods of modifying the curd texture of milk. The present report aims to evaluate the nutritional significance of soft curd milks, particularly in the feeding of infants, in the light of available experimental and clinical evidence.

EXPERIMENTAL EVIDENCE

Rate of Digestion in Vitro.—Efforts to relate curd tension to the rate of peptic digestion in vitro have shown striking differences in favor of soft curds. Doan and Welch,³ for example, used untreated cow's milk and found that the milk which produced softer curds was more readily digested under laboratory conditions, especially if the digestion mixture was agitated. They studied also the effects of varying the pH between 2 and 6 and found that increased acidity caused a greater acceleration of digestion in soft curd milk than in milk with higher curd tension. They observed that the digestion of hard curd milk (as measured by the increase in soluble nitrogen) progressed at a constant rate but that the digestion of soft curd milk was rapid at first and slower in the later stages. The slowing-up process was attributed in large measure to a reduction by digestion itself of the surface area remaining to be acted on by the digestive enzymes. From these clear-cut experiments it may be concluded that, other things being equal, the ability of milk to form a fine friable coagulum is a decided advantage in hastening the gastric digestion of casein. But of course artificial digestion experiments may not be a true representation of what takes place in the living organism. A review of the available biologic evidence suggests, indeed, that curd tension is important in the rate of digestion of casein but that other factors must also be considered.

Emptying Time of Stomach.—A number of investigators have studied the problem of soft curd milk by observing the emptying time of the stomach after the ingestion of different types of milk. Doan and Welch³ performed regurgitation experiments on three normal adults and concluded that natural soft curd milk leaves less residue in the stomach after a given interval than does milk having a high curd tension. They attributed the more rapid emptying to the lower casein and fat contents of the milk, as well as to the softer curd. Espe and Dye⁴ made use of dogs with Pavlov pouches and, assuming that the duration of secretion from the pouch after a milk meal was an index of the stay of the milk in the stomach, they likewise found a more rapid emptying time after soft curd milk had been ingested. Their conclusion that the effect is due to curd character may be open to criticism in the light of the observation of Hess, Koch and Sennewald⁵ that adult dogs normally fail to coagulate milk completely. Observations on calves and rats

killed at definite intervals after the ingestion of milk, however, have indicated that natural soft curd milk travels more rapidly through the alimentary tract.⁶ In Brennemann's^{1a} experiments boiled milk was found only in scant amounts in the human stomach after three hours, while raw milk was recovered in similar amounts after five hours.

In the light of the foregoing results it is difficult to interpret the observations of Ogilvie and Peden,⁷ who found no differences between raw and boiled milk in the rate of emptying of the stomach of infants as determined by the stomach tube, or in the amount of soluble nitrogen of the gastric contents. Their conclusions as to the rate of emptying are open to the criticism that the stomach tube is too small to withdraw large curds, which may be present. Studies in which barium sulfate and the fluoroscope were used for observing the rate of digestion of milk in from one to four adults indicated that evaporated milk and milk modified by the addition of citrate, alkali or barley water did not leave the stomach significantly quicker than ordinary milk.⁸

Schlutz and Fetter⁹ used the balloon method to follow gastric motility after milk meals in four children and concluded that acid milks leave the stomach earlier than either evaporated or untreated milks. The rate of digestion of acid milk mixtures must be considered not only from the standpoint of curd tension but also from the standpoint of reduced buffer capacity. Buffer substances, which in milk are represented chiefly by protein and phosphates, take up added acid and thus resist changes in pH . In order to effect a given small change in pH , approximately three times as much acid must be added to cow's milk as to breast milk. Marriott and Davidson¹⁰ determined the pH of the gastric contents at the height of digestion and found that a greater acidity is attained after the ingestion of human milk than of cow's milk. Marriott¹¹ suggested the addition of acid to compensate for the larger amounts of hydrochloric acid held by cow's milk and to bring the gastric contents to the approximate pH attained after the ingestion of human milk. Acid milk mixtures, therefore, might be expected to be digested more rapidly not only because of the lower curd tension but also because the gastric contents of the infant are more quickly brought into the range of acidity where the proteolytic enzymes of the gastric juice may act. Other observations on this subject will be discussed under the heading of clinical observations.

The determinations of soluble nitrogen by Schlutz and Fetter⁹ suggested that acid milks are more quickly digested than mixtures made from powdered milk or untreated milk. Hess, Koch and Sennewald⁵ believe that acid milks show a more rapid digestibility only in the early stages of digestion. These investigators determined free and total acidity and pH of the gastric contents at half hour intervals for two hours following the ingestion of modified milks by puppies. The pH of the gastric contents after one-half hour was found to depend largely on the acidity of the meal. After two hours the pH was the same, regardless of the acidity of the milk that was ingested.

CLINICAL OBSERVATIONS

The evidence on the importance of low curd tension in hastening the emptying time of the stomach is conflicting, but the general consensus is that soft curd milk is more rapidly digested in the stomach. The evidence from clinical studies of the value of soft curd milk is likewise conflicting. Superior qualities for natural soft curd milk as a routine and special food for infants have been claimed by Hill¹² and denied by Elias¹³ and

by Morris and Richardson.¹⁴ Cow's milk modified by the base exchange method, which is therefore lower in calcium, has been reported by Rogers, Pavey and Williams¹⁵ as suitable for the complementary feeding of infants. Evaporated,¹⁶ sweetened condensed¹⁷ and powdered milks¹⁸—all of which usually form soft, flocculent curds—have been used with clinical success in the feeding of normal infants. The acid milks have enjoyed considerable popularity, particularly during the last decade. The agents employed have included lactic acid¹⁹ and sauerkraut juice,²⁰ hydrochloric acid,²¹ citric acid²² and citrus fruit juices²³ and vinegar.²⁴ Milks so modified have been reported to be suitable for the feeding of many infants, and valuable in the feeding of babies born prematurely and those with digestive disorders. Although acid milks had long been used empirically and the high buffer value of cow's milk was reported in the last century, it has been the studies of Marriott which in recent years have emphasized the desirability of adding acid to cow's milk. Brennemann,¹⁶ who as a result of his earlier experiments interpreted the value of acid milks in terms of curd texture, undertook a crucial clinical experiment to evaluate the rôle of the acid. He and his associates were unable to detect any difference between two groups of fifty infants fed diets identical except for lactic acid. Evaporated milk was used for both groups. Brennemann was forced to the conclusion that curd texture, and not acidity, is of prime importance and that the value of acid milks lies in the modification of the curd. This conclusion has been amply supported by the work of Lynch¹⁸ and of Jeans and Stearns.²⁵ Lynch observed identical rates of growth over a period of six months in two groups of infants fed powdered milk preparations with or without added citric acid. He found that less acid was needed for dried milk than for fresh milk and he expressed doubt as to the need for any acid at all in preparations made from powdered milk. In the experiments of Jeans and Stearns, acid milks prepared with lactic and citric acids, milk coagulated with a rennin-pepsin preparation, and evaporated milk proved equally effective in promoting good growth and in retentions of nitrogen, calcium and phosphorus.

25. Jeans, P. C., and Stearns, Genevieve: Factors Possibly Influencing the Retention of Calcium, Phosphorus and Nitrogen by Infants Given Whole Milk Feedings: I. The Curdling Agent, *J. Pediat.* 8: 403 (April) 1936.

As judged by growth, general condition,²⁶ and retention²⁷ of nitrogen, calcium and phosphorus it may be concluded that, in general, milks which form soft curds are well tolerated and utilized by infants and children.

SUMMARY

There is evidence that a variety of milk preparations which yield soft curds are well tolerated and well utilized by infants, children and older persons. In general, milk that has a low curd tension as determined by appropriate laboratory methods leaves the stomach more quickly than milk that does not have this property. Such digestion as takes place in the stomach is more quickly accomplished when the curd is soft. The evidence is meager, however, that any soft curd milks are "better digested" or more completely digested than ordinary boiled milk.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

STOKELY'S STRAINED BEEF BROTH

Manufacturer.—Stokely Brothers & Company, Indianapolis.

Description.—Canned, strained beef broth, slightly seasoned with salt.

Manufacture.—Fresh selected government inspected beef is cooked in a definite amount of water for six hours at 100 C. The beef is removed and the broth is strained, heated to 100 C., slightly seasoned with salt and filled into enamel-lined cans, which are sealed and processed for sixty minutes at 116 C.

Analysis (submitted by manufacturer).—Moisture 98.2%, total solids 1.8%, ash 1.1%, sodium chloride (NaCl) 0.8%, fat (ether extract) negligible, protein (N \times 6.25) 0.8%, crude fiber none, reducing sugar as dextrose 0.1%, sucrose 0.1%, carbohydrates other than crude fiber (by difference) none, p_{H} 6.19, alkalinity of ash, cc. normal acid/Gm. 2.25.

Calories.—0.03 per gram; 0.9 per ounce.

Claims of Manufacturer.—Specially prepared strained beef broth for infant and for invalid feeding.

PILLSBURY'S BRAND FARINA

Manufacturer.—Pillsbury Flour Mills Company, Minneapolis.

Description.—Granular wheat endosperm or farina, practically free of germ and bran.

Manufacture.—Wheat is cleaned, washed, scoured and crushed and the bran and germ are separated from the flour middlings (endosperm) by the usual milling methods. Endosperm graded to uniform granulation is heated to destroy any insect infestation and packed in cartons.

Analysis (submitted by manufacturer).—Moisture 8.7%; ash 0.4%, fat (ether extraction method) 0.8%, protein (N \times 5.7) 10.5%, reducing sugars as dextrose 0.2%, sucrose 1.3%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 79.2%.

Calories.—3.7 per gram; 105 per ounce.

MORRIS SUPREME BRAND EVAPORATED MILK

Distributor.—Morris & Company, Division of Armour & Company, Chicago.

Packer.—Armour & Company, Chicago.

Description.—Canned, unsweetened, sterilized, evaporated milk, the same as Armour's Brand Evaporated Milk (THE JOURNAL, June 16, 1934, p. 2025).

26. Evans.¹⁷

27. Willard, Alice C., and Blunt, Katherine: A Comparison of Evaporated with Pasteurized Milk as a Source of Calcium, Phosphorus and Nitrogen, *J. Biol. Chem.* 75: 251 (Oct.) 1927. Jeans, P. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, JUNE 19, 1937

THE ATLANTIC CITY SESSION

After all the superlatives are exhausted, the Atlantic City session arises to demand additional ones. Never in the history of medicine has there been such an assemblage of physicians, and never before such a wealth of material for their interest and instruction. Some 9,764 doctors registered their attendance in Atlantic City, 1,295 more than registered at the great session of 1935, the high mark up to the present. Moreover, the session in Atlantic City in 1935 was graced by the presence of 303 visitors from Canada who did not contribute to the mark of the present occasion. Every hotel on the boardwalk was filled to capacity and most of the visitors remained throughout the entire week.

In the House of Delegates, affairs of science and of government commanded the attention to such an extent that several extra sessions of the representative body were necessary to complete the tasks before it. Every physician in the United States should read the minutes of this meeting in order that he may personally be more definitely aware of the serious matters which concerned the delegates. The significant features involved resolutions leading toward a change in the nature of the practice of medicine, a decision by the House of Delegates to cooperate with the government in working out plans for the care of the indigent sick on direct request from the government, and a personal visit to the House of Delegates from Senator James Hamilton Lewis of Illinois, bringing an authorized message from the President.

The Committee on Contraception presented a simple, dignified report of its deliberations, which was unanimously adopted by the House of Delegates. This places on the various councils the responsibility for the examination of products used in contraception. It recognizes also the necessity for teaching the scientific aspects of both fertility and sterility. It recommends that doctors inform themselves concerning their legal rights and responsibilities in relationship to the pre-

vention of conception, and it suggests that all such practice be in regularly licensed clinics under medical control.

Two definitely new procedures were also adopted by the House of Delegates and are mentioned here since they will definitely affect the work of the Association. A resolution was passed recommending the development of a distinguished service medal with citation to be presented each year at the time of the annual session to a physician who has rendered such service for the advancement of the art and science of medicine. The House of Delegates also adopted a resolution providing for the selection of a place of meeting three years beyond the time of the selection. There are many reasons for this change. Most significant is the fact that the meetings of the Association have grown so large that there are but few cities in the United States which can accommodate them satisfactorily. These are cities which contain large auditoriums capable of housing suitably the technical and scientific exhibits and also of providing acceptable halls for the meeting places of the sections. Since the number of such cities is limited and since the demand on them is great, it is necessary to make early choice in order to secure a time that will be satisfactory to the great numbers of physicians who now attend the annual session.

The reports of the officers and trustees of the Association, as well as those of the several councils and bureaus, were highly commended by the House of Delegates. New resolutions recommended cooperation in securing drivers' licenses in various states so as to aid in the prevention of fatalities from motor accidents; encouragement of investigation of teaching of osteopathy by an unbiased, nonpartisan source; recommendation to the Social Security Board that examinations for blindness be carried out only by doctors of medicine, competent in diagnosis and treatment of diseases of the eye; encouragement in the use of motion pictures in public and in medical education and for reviews and censorship of films used for advertising promotion; recommendation to the Council on Medical Education and Hospitals for more extended inspection of hospitals, and also resolutions on many other subjects, which will become apparent in the minutes of the session.

The General Scientific Meetings commanded tremendous audiences, and the motion picture clinic on syphilis was seen and heard by at least 7,500 visitors. More than 300 papers were read in the scientific sessions. The symposiums on neuropsychiatry, papers on the use of sulfanilamide, and meetings of many of the sections attracted capacity audiences.

The entertainment proffered through the Woman's Auxiliary and through the Local Committee on Arrangements was exceptional. The dinner to the House of Delegates presented a galaxy of famous figures in the field of medicine, and excellent entertainment was interspersed among their addresses. The

Opening General Meeting attracted an audience of between six and seven thousand. The addresses by Drs. Heyd and Upham were significant. The singing by the Madrigal Singers from Philadelphia elicited tremendous applause. So numerous were the visitors to the President's reception that hours were required for the passing of those who wished to greet the officers personally in the line of reception.

A veritable deluge of representatives of the press and of the various illustrated magazines descended on Atlantic City several days before the session and worked busily throughout. All the New York and Philadelphia newspapers, as well as the *Detroit Free Press*, the *Washington Star*, the *Chicago Tribune* and many others sent individual correspondents. Four men represented the Associated Press and there were others from all the important press services, including the five reporters who shared the Pulitzer prize in journalism this year. *Time*, *News Week* and *Life* were especially represented.

The Scientific Exhibit has come to represent what is probably the most noteworthy of the many extraordinary features of the annual session of the American Medical Association. Innumerable physicians who come to the meeting spend their entire time during the week visiting these exhibits. The collections in this year's session were beyond any displays ever made anywhere before. In scientific value, appearance, attendance, quantity, arrangement and in every other manner they reached the heights. So great was the attendance at the exhibits that it was again necessary that they be held open until 4 o'clock on Friday afternoon. All that has been said of the Scientific Exhibit applies equally to the Technical Exposition. Manufacturers have learned more and more the importance of making the exposition educational. So vast a number of physicians were constantly in and out of the attractive booths that the attendants at the exhibits found themselves well nigh physically and mentally exhausted before the session was completed. Few physicians realize how many thousands of persons are involved in employment in these sessions.

It is impossible to thank sufficiently the Local Committee on Arrangements. Every physician was promptly supplied with suitable quarters. The facilities for every purpose more than met the needs of the occasion. Sunshine prevailed, tempered by cooling winds. An unusual touch was a final word of farewell and congratulations announced over the loud speakers in railroad stations to various notables as they departed from the convention city. Some may have thought that the tremendous attendance in 1935 was due to the unusual character of the occasion and the visiting of our Canadian colleagues. No doubt, that played a large part. However, the vast assemblage of this year must be largely credited to the appeal of Atlantic City as a suitable place for such a scientific session.

THE TRANSPORT OF CARBON DIOXIDE BY THE BLOOD

The mode of transport of carbon dioxide by the blood, closely linked with the acid-base balance, has been much studied during the past two decades, especially in America, Great Britain and Denmark. Noteworthy discoveries have made this one of the most fascinating chapters in modern physiology. Oxygen, a neutral gas, and carbon dioxide, which forms carbonic acid when dissolved in water, are exchanged for each other in the lungs and in the tissues; nevertheless the organism maintains the degree of alkalinity of the plasma at an almost constant level. L. J. Henderson¹ made the brilliant deduction, later abundantly confirmed, that hemoglobin when combined with oxygen is a stronger acid than when in the reduced state. This variability in the acid strength of hemoglobin, he concluded, is the chief factor in preventing the plasma from becoming more alkaline in the lungs and acid in the tissues. In the latter case, since production of carbon dioxide under ordinary conditions is proportional to oxygen consumption, the mechanism is peculiarly adapted to meeting the conditions that arise locally in various tissues under varying conditions of activity.

Attention was then directed toward the manner in which the effects of reactions taking place in the red blood cells are transmitted to the plasma. Van Slyke and his co-workers² found that a great part of the carbon dioxide entering the blood is at once taken up by the red cells and converted to bicarbonate, a considerable part of which is then exchanged for chloride from the plasma, the acid-base balance in the plasma being thus maintained. The elucidation of these mechanisms, with the first comprehensive description, both qualitative and quantitative, of the equilibria between red cells and plasma constituted a major step forward.

Henriques,³ turning his attention to the dynamics of these processes, found that the time spent by the blood in the capillaries of the tissues and lungs—about one second as an average—is too short for the unaided attainment of such equilibria as had been studied. This is especially true of the formation of carbonic acid from the combination of carbon dioxide with water and of the reverse process, the dehydration of carbonic acid to gaseous carbon dioxide, the latter occurring principally in the lungs. This led to the discovery of a catalyst, first purified by Meldrum and Roughton⁴ and named by them "carbonic anhydrase." This catalyst, which is present in the red cells but not in the plasma,

4. Meldrum, N. U., and Roughton, F. J. W.: Carbonic Anhydrase: Its Preparation and Properties, *J. Physiol.* **80**:113 (Dec. 5) 1933.

has the property of enormously accelerating the reaction between carbon dioxide and water in both directions and is of great physiologic significance in the dynamics of carbon dioxide transport.

A further consequence of the pioneer work of Henriques was the demonstration of a direct combination between hemoglobin and carbon dioxide in the form of a "carbamino" compound, extensively investigated by Roughton and his co-workers⁵ and others. Thus to the three previously known forms of carbon dioxide in the blood (dissolved carbon dioxide, carbonic acid and bicarbonate) is added a fourth, called "hemoglobin carbamate" by Stadie and O'Brien,⁶ again of great physiologic significance. As Ferguson⁷ shows, this discovery does not invalidate the importance of the variability in the acid strength of hemoglobin, as discovered by Henderson, but rather extends and clarifies its significance.

Both the newer and the older discoveries have been consolidated by Stadie and O'Brien,⁸ who have been able by the application of the fundamental law of mass action to reduce at least the chief elements in the behavior of carbon dioxide in the blood to quantitative terms and to evaluate the part played by each of the processes concerned in an extraordinarily efficient mechanism for transporting this substance from the tissues to the lungs with minimal changes in the degree of alkalinity of the blood. It emerges more clearly than ever before that hemoglobin, by virtue of its peculiar properties, accounts directly and indirectly for the transport of approximately 90 per cent of the carbon dioxide carried from the tissues to the lungs. That the mechanisms involved in the transport of oxygen and of carbon dioxide, although differing radically in character, are closely interrelated has been recognized since the demonstration⁸ of the influence of oxygen and carbon dioxide on the behavior of each other in the blood. From the newer knowledge there is a clearer definition of the manner in which oxygen in the lungs helps to "pump" carbon dioxide out of the blood and in which carbon dioxide in the tissues helps to "pump" oxygen from the blood, both processes being vital to the rapid exchanges taking place during the short stay of the blood in the capillaries.

Many further details remain to be added. Nevertheless the successive discovery of the variable acid strength of hemoglobin, of the equilibria between red cells and plasma, of carbonic anhydrase and of hemoglobin carbamate, and the elucidation of their physiologic significance are accomplishments that constitute a triumph for modern physiology.

BREAST MILK AND LYSOZYME

In large institutions there are frequently shortages in the supply of breast milk owing to variations in supply and demand. At the New York Foundling Hospital, Scheuer and Duncan¹ have attempted to solve this problem by pasteurizing breast milk in ordinary nursing bottles at 175 F. for thirty minutes on three successive days. The bottles, stoppered with sterile corks, are sealed and stored in a refrigerator at from 38 to 52 F. The milk has been found to remain sterile for as long as two years. These investigators consider it a satisfactory substitute for fresh breast milk and have found also that the fecal flora of infants thus fed is approximately that of infants given the fresh breast milk.

Other apparently important factors have been discussed by other investigators. Thus in 1931 Rosenthal and Lieberman² found a lytic principle in the stools of nurslings which was identified as lysozyme, a substance previously discovered in various human and animal tissues by Fleming,³ which had "properties akin to ferments." It was absent from cow's milk, the common milk formulas, and the stools of artificially fed infants but was found in the stools of breast-fed babies after the fourth day. Its characteristic property is the dissolution of live bacteria in culture; it inhibits the growth of *Bacillus coli* at 37 C. and lyses it at 56 C. It was found relatively thermolabile and tended to stabilize the gram-positive intestinal flora of nurslings.

Recently, Blatt and Kessler⁴ made bacterial counts on plate cultures of expressed human milk and determined what they called the "lytic index" of the various samples. The milk was collected by aseptic technic and was refrigerated at from 9 to 12 C. The samples collected by manual expression of the breasts had a lower initial bacterial count than those collected by means of a pump, whether hand or electrically operated, and the lytic index was also higher. This difference is apparently due to the large area of breast tissue bathed by the expressed milk when the electric pump is used, the milk being thus exposed to contamination. The low initial count could be maintained for as long as seventy-two hours when the milk was kept at a low temperature. *Staphylococcus albus* was the predominating organism. Boiling reduced the lytic action greatly, and repeated boiling caused complete inactivation. Raw breast milk was fed to premature infants on the theory that implantation of the gram-positive bacteria normally present in the stools of breast-fed infants might be accomplished. No diarrhea developed in the children thus fed. It is thus clear that all the factors relating to breast milk are not even yet wholly understood.

Current Comment

IRVIN ABELL—PRESIDENT-ELECT

In an election in which every candidate was unopposed, indicating a remarkable unanimity of action by the representatives of organized medicine, Dr. Irvin Abell of Louisville, Ky., was made President-Elect of the American Medical Association in the annual session at Atlantic City. The popularity of the candidate is not surprising in view of his long record of service to the medical profession. In the American Medical Association he served as a delegate from Kentucky in the House of Delegates at the annual sessions of 1922, 1924-1928 and 1930-1935. He was a member and at various times has served as chairman of many important reference committees in the House of Delegates. Since 1931 he has been a member of the Council on Scientific Assembly and since 1935 its chairman. Dr. Abell was born in Lebanon, Ky., Sept. 13, 1876. He received his A.M. degree from St. Mary's College, St. Mary, Ky., in 1894 and his M.D. from the Louisville Medical College in 1897. He continued his studies at the University of Berlin in 1898. Since 1900 he has practiced in Louisville, Ky., becoming professor of surgery in the University of Louisville in 1904 and serving continuously in that position. He has been visiting surgeon of the Louisville Public Hospital and the St. Joseph Infirmary, and consulting surgeon for the Children's Free Hospital and the Kosair Hospital for Crippled Children. Among other positions indicating his executive ability, he is a director of the Commonwealth Life Insurance Company, the Fidelity and Columbia Trust Company and the Louisville Foundation, and also a trustee of the University of Louisville. Dr. Abell holds memberships in the American College of Surgeons, the American Surgical Association, the Southern Medical Association, the Southern Surgical Association, the American Urological Association and the American Gastro-Enterological Society. He served recently as chairman of the McDowell Committee, which purchased the McDowell home in Danville, Ky., and aided in its restoration. During the World War he was a Lieutenant Colonel, commanding Base Hospital No. 59, then Colonel in the Medical Officers Reserve Corps

and commanding officer of the United States Army Reserve Corps Hospital No. 59. Noted for his geniality and his lovable character, he should have the confidence and the cooperation of all the members of the great organization in which he is now given leadership.

INTRA-UTERINE FETAL RESPIRATION

Is intra-uterine respiration of the amniotic fluid a normal function in the full term mammalian fetus? Does it serve a useful purpose in the dilation of the pulmonary alveoli and bronchial passages? Some unconventional conclusions by Snyder and Rosenfeld¹ of the department of pharmacology at Johns Hopkins University School of Medicine were based on laparotomy studies on seven full term pregnant rabbits, the operations being performed beneath the surface of a bath of Ringer's solution at 37 C. In these seven operations they found twenty-five full term fetuses, fourteen of which showed active respiratory movements at the time of laparotomy. To demonstrate an actual tidal flow of amniotic fluid in the respiratory tract of these fetuses, 1 cc. of 50 per cent india ink was injected into each amniotic sac. From one to sixty minutes after injection the trachea of each fetus was clamped and the lungs were examined and fixed in solution of formaldehyde before removal of the clamp. The fixed lungs were studied by histologic methods. In all fetuses showing demonstrable respiratory movements the lungs were blackened by the inspired india ink. The eleven apneic fetuses showed lungs macroscopically and microscopically free from carbon particles. Litter mates breathing at different rates showed a correlation between the rate of respiration and the depth of pulmonary blackening. In a fetus breathing at the rate of ninety-six per minute, for example, the lungs were much darker than those of a litter mate breathing at a rate of ten per minute. The authors conclude that "amniotic fluid normally occupies the alveoli of the fetal lung," that "spontaneous respiratory movements are responsible for a tidal flow in the respiratory tract," and that this "interuterine respiration is of functional significance in the development of a normal lung."

IRVIN ABELL, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE EIGHTY-EIGHTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 7-11, 1937

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 7

The House of Delegates convened in the Renaissance Room of the Ambassador Hotel and was called to order at 10:05 a. m. by the Speaker, Dr. N. B. Van Etten.

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. Benjamin F. Bailey, Nebraska, who reported that 102 delegates with proper credentials had registered but that the number would be greatly increased before the first session of the House adjourned. Dr. Bailey read a letter from the Section on Nervous and Mental Diseases submitting the name of Dr. Hans H. F. Reese as its delegate since the duly elected delegate and alternate from that section were unable to be in attendance. On motion of Dr. J. Gurney Taylor, Wisconsin, seconded by Dr. Arthur C. Morgan, Pennsylvania, and carried, Dr. Reese was seated.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the report of the Reference Committee constitute the roll of the House. The motion was seconded by Dr. George W. Kosmak, New York, and carried.

Adoption of Minutes of Kansas City Session

It was moved by Dr. George W. Kosmak, New York, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, that the minutes of the Kansas City session be adopted as printed.

Message of Sympathy

The Secretary announced that his assistant in the House of Delegates, Miss Hattie A. Niehoff, had been called home because of the sudden death of her mother, and it was moved by Dr. Samuel J. Kopetzky, New York, seconded by Dr. George W. Kosmak, New York, and carried, that the House instruct its Speaker to send a telegram of sympathy to her.

Official Delegates and Invited Guests

The Secretary announced that the House of Delegates would be honored this year by the presence of official delegates and guests from foreign countries, who would be presented to the House at some later time during the session.

Executive Session—Monday Morning, June 7

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, the House went into Executive Session at 10:25 a. m., the membership to consist of duly accredited delegates, general officers, past and present, delegates from the American Bar Association and presidents and secretaries of constituent state medical associations.

The Sergeants-at-Arms polled the House, after which the House went into Executive Session.

At the request of the Speaker, the Secretary read telegrams received from Hon. J. Hamilton Lewis, U. S. Senator from Illinois, requesting the privilege of addressing a section of the Association.

It was moved by Dr. G. Henry Mundt, Illinois, seconded by Dr. A. T. McCormack, Kentucky, and carried, that the Secre-

tary be instructed to inform Senator Lewis that he would be welcome to appear before the House of Delegates, the time best suited being at the beginning of the Executive Session on Tuesday afternoon, June 8.

The House rose from Executive Session on motion of Dr. C. E. Mongan, Massachusetts, seconded by Dr. J. D. Brook, Michigan, and carried.

Address of the Speaker, Dr. N. B. Van Etten

The Vice Speaker, Dr. H. H. Shoulders, Tennessee, presided while the Speaker, Dr. N. B. Van Etten, read his address, which was referred to the Reference Committee on Reports of Officers:

Members of the House of Delegates:

Many of you are so familiar with the figures that play their parts on this stage that you could not fail to recognize them in any other setting. The classic features of the distinguished Secretary must be indelibly engraved on your memory. Presidents and other officers have identified themselves in this spotlight and have been embarrassed by your scrutiny as they have labored for your approval. On the other hand, those you have honored with the courtesy of these vantage points have been looking into your faces and beyond your faces with the deepest interest in your foreground and your background. Each one of you has grown up through the fundamental culture of your homes, your schools, your social contacts, your own investigations, your appreciation of your opportunities, your realization of your responsibilities and your emotional reactions until what you are has made such an impression on those who know you that they have chosen you to represent them here.

From 1846 until this day your seats have been occupied by selected persons. You represent 100,000 physicians. Those who delegated you are the most highly educated groups of citizens of the Republic, and they selected you because of your inherent quality. They have delegated you to interpret their desires for the best interests of organized medicine. I do not believe that there is anywhere another assemblage of 170 men that is superior in intelligence. You are the most important officers of American medicine and you in turn have delegated authority to officers and trustees who are bound to execute your mandates.

The American Medical Association has been freely accused of being reactionary, static, slow, and unresponsive to social demands. Some of our own members are impatient to meet social problems quickly. If there is justice in these complaints you must regard them as valid criticisms of this legislative body because you have made the policies of the Association. Many of these criticisms are evolved in ignorance. Captious criticism is frequently the expression of those who seek to evade responsibility for their own incompetence. Shifting responsibility is a common pastime.

Early records of organized medicine in the era of Babylonian culture 4,000 years ago reveal organization of medical men to protect the public from quacks and charlatans and also for self preservation—and these ideals have prevailed through the centuries.

In our early American history when competitive life was less intense, physicians seem to have associated themselves mainly for deliberative purposes. In those early days the House of Delegates had simpler problems, mostly concerned with medical education and licensure. With the evolution of American society there has come a need for concerted labors and a demand that deliberation be translated into action. Pressure groups are pushing the medical profession into unfamiliar

channels that lead to organization for political progress and for defensive activity against outside control.

This House of Delegates has a legislative responsibility which is a serious one and must not be taken lightly. Article 5, Section 1, of the Constitution reads: "The legislative powers of the Association reside in the House of Delegates. The House of Delegates shall transact all business of the Association not otherwise specifically provided for in this Constitution and By-Laws, and shall elect the general officers."

You are the policy makers, you elect the general officers and the Trustees who are obligated to carry out your instructions, but these Trustees also have powers limited by the Constitution in Article 7, which reads: "The Board of Trustees shall have charge of the property and financial affairs of the Association and shall perform such duties as are prescribed by law governing directors of corporations." You have, however, laid on the Trustees, by your resolutions, many other duties which they must try to perform to the best of their abilities.

Sitting with the Trustees, as is my privilege, I have been greatly impressed by their meticulous fidelity to their obligations and also by the fact that very little careless legislation passes this House.

Although the complexion of the House of Delegates changes from year to year, there are fortunately a sufficient number of seasoned members to guarantee continuity of experience. The lessons of the past may wisely check ill-considered action without strangling vitality.

Thirty-six of the delegates elected to this House began their services fifteen or more years ago, twenty-one attended their first session twenty or more years ago, and eleven delegates began their activities in this department of organized medicine twenty-five or more years ago. The service of these delegates has not in every instance been continuous, but their presence at this session is evidence of the high esteem in which they are held in their home states. Their long and distinguished service has materially strengthened the respect in which the House of Delegates is held by American physicians. While all these delegates deserve commendation, it seems fitting that eleven of them should be placed on an honor roll today.

For the purpose of identifying them to the new members, I would like them to rise for a moment as their names are called.

Dr. Thomas S. Cullen, Maryland, attended his first session in 1902 and is now attending his thirtieth session; he is dean in point of attendance.

Dr. George F. Johnston, Wyoming, first came to the House in 1903 and is serving his thirteenth session.

Dr. Edward H. Cary, Texas, attended his first session in 1906. He has been seventeen times a delegate, attended four other sessions as a Trustee, one as President-Elect and one as President and is now starting his twenty-fourth session.

Dr. Arthur T. McCormack, Kentucky, attended his first session in 1908 and begins his twenty-fifth session today.

Dr. Edgar A. Hines, South Carolina, attended his first session in 1910 and enters on his twenty-eighth session this morning.

Dr. Roger L. Lee attended his first session in 1911 and is now attending his twelfth session.

Dr. Arthur C. Morgan, Pennsylvania, began his service in 1911 and is now attending his eleventh session.

Dr. Ben R. McClellan, Ohio, also began his service in 1911 and is now serving at his twenty-fourth session.

Dr. Grant C. Madill, New York, attended his first session in 1912 and enters his eighteenth session today.

Dr. William D. Johnson, New York, also came the first time in 1912 and begins his eighth session this morning.

Dr. Holman Taylor, Texas, also belongs to the class of 1912 and has regaled the House with wit and wisdom for twenty-two sessions.

There are five other men who deserve special medals with palms for consecutive, uninterrupted service for more than twenty years, exemplars of extraordinary appreciation of their value to organized medicine. I should like them to rise also. They are: Dr. J. H. J. Upham, Ohio, whose twenty-four sessions have not been interrupted; Dr. Charles J. Whalen, Illinois, whose twenty-three sessions have had no interruption; Dr. Rock Sleyster, Wisconsin, whose twenty-three sessions have had no interruption; Dr. J. D. Brook, Michigan, who is here for his twenty-second session, and Dr. Arthur J. Bedell, New York, who now enters his twenty-first session.

Having identified the veterans, I would like to introduce seventeen men who are here for the first time. Will they please rise as their names are called?

Arkansas.....William H. Mock
California.....Robert A. Peers

Delaware.....Stanley Worden
Illinois.....E. S. Hamilton
Kentucky.....E. L. Henderson
Massachusetts.....Walter A. Lane
Michigan.....T. R. K. Gruber
New Jersey.....Blase Cole
New York.....James H. Borrell
New York.....Thomas H. Cunningham
Vermont.....A. B. Soule Jr.
Washington.....Raymond L. Zech
Wisconsin.....Gunnar Gundersen
Alaska.....Noble Dick
Philippine Islands.....Frederick W. Meyer
Puerto Rico.....Ramón M. Suárez
United States Navy.....Robert E. Stoops

To you gentlemen, the Speaker extends the right hand of fellowship and asks your active participation in all discussions. I trust that a Thomas Cullen and an Edward Cary and an Edgar Hines may be found among you and that you may be returned from your states to break all records.

May I add that all members of the House should remember that they have not discharged their full duty until they have followed their resolutions to the Reference Committees to which they have been committed and may I also remind you that all Reference Committee rooms are open to all of you.

It is desirable that Reference Committees meet at the earliest possible moment and that they make every effort to prepare their reports so that the business of the House may move as rapidly as is consistent with parliamentary procedure.

Since the Kansas City session last year thirty-four former delegates or officers have died. The dates following their names indicate their years of service:

H. L. Alkire, Topeka, Kan., 1908.
William H. Arthur, United States Army, 1915.
Elias Hudson Bartley, Brooklyn, 1909-1910.
Arthur G. Bennett, Buffalo, 1926.
William Joseph Birkofer, Gothenburg, Neb., 1910.
Daniel S. Dougherty, New York, 1927-1928; 1930-1932; 1935.
William Duffield, Los Angeles, 1932.
Duncan Eve Sr., Nashville, Tenn., 1903-1904 (first vice president, 1887).
Frank Y. Gilbert, Portland, Maine, 1914; 1917; 1919; 1927; 1930.
John F. Hagerty, Newark, N. J., 1926-1927; 1930-1934; 1935 Special Session; 1935-1936.
Rufus B. Hall, Cincinnati, 1908-1909; 1919.
S. W. Hammond, Rutland, Vt., 1905.
George A. Hare, Fresno, Calif., 1912-1915.
A. M. Hayden, Evansville, Ind., 1906; 1908.
J. Allison Hodges, Richmond, Va., 1923.
Thomas B. Holloway, Philadelphia, 1918.
Collins H. Johnston, Grand Rapids, Mich., 1908.
A. Haines Lippincott, Camden, N. J., 1935.
W. C. Lyle, Augusta, Ga., 1911; 1914; 1922.
J. Tate Mason, Seattle, Wash., 1928; 1930-1934; 1935 Special Session (President-Elect, 1935-1936; President, 1936).
William H. Mayer, Pittsburgh, 1920-1934; 1935 Special Session; 1935.
Henry P. Newman, San Diego, Calif., 1916-1918.
Edward S. Reynolds, Boston, 1921.
William L. Rich, Salt Lake City, 1923.
W. B. Scull, Philadelphia, 1911; 1920.
Sidney K. Simon, New Orleans, 1922.
Frank Smithies, Chicago, 1927-1930 (member of Council on Scientific Assembly, 1930-1935).
Willard Springer, Wilmington, Del., 1902; 1917.
Wells Teachnor Sr., Columbus, Ohio, 1924-1925; 1927-1934; 1935 Special Session; 1935-1936.
Randolph Winslow, Baltimore, 1905-1906; 1911; 1913; 1916-1923; 1927-1934; (member of Judicial Council, 1915-1922).
H. M. Workman, Tracy, Minn., 1905-1906.
John T. Axtell, Newton, Kan., 1913.
James N. Vander Veer, Albany, N. Y., 1926-1935.
George A. Leitner, Piermont, N. Y., 1923-1935; (for many years served as Sergeant-at-Arms).

Many of us have vivid memories of these, our friends. I am sure that we shall be motivated by their inspiration.

At the request of the Vice Speaker, the members of the House rose and stood for one minute in silent tribute to the memory of departed delegates.

On motion of Dr. Charles H. Goodrich, New York, seconded by Dr. Walter E. Vest, West Virginia, the House consented to the appointment of a Reference Committee on Executive Session.

Reference Committees

The Speaker presented the following names of members of Reference Committees:

SECTIONS AND SECTION WORK

J. E. Paullin, Chairman.....	Section on Practice of Medicine
Arthur J. Bedell.....	Section on Ophthalmology
Elbridge J. Best.....	California
J. Allen Jackson.....	Pennsylvania
Charles R. Scott.....	Idaho

RULES AND ORDER OF BUSINESS

H. A. Luce, Chairman.....	Michigan
Wyndham B. Blanton.....	Virginia
J. P. DeWitt.....	Ohio
Samuel J. Kopetzky.....	New York
Raymond L. Zech.....	Washington

MEDICAL EDUCATION

F. S. Crockett, Chairman.....	Indiana
George Blumer.....	Connecticut
J. T. Christison.....	Minnesota
Charles A. Dukes.....	California
Walter E. Vest.....	West Virginia

LEGISLATION AND PUBLIC RELATIONS

Terry M. Townsend, Chairman.....	New York
J. C. Flippin.....	Virginia
Harold T. Low.....	Colorado
Stanley H. Osborn.....
.....Section on Preventive and Industrial Medicine and Public Health
J. Gurney Taylor.....	Wisconsin

HYGIENE AND PUBLIC HEALTH

James O. Graves, Chairman.....	Louisiana
Lewis B. Bates.....	Isthmian Canal Zone
W. F. Draper.....	United States Public Health Service
Meredith Mallory.....	Florida
G. Henry Mundt.....	Illinois

AMENDMENTS TO CONSTITUTION AND BY-LAWS

J. N. Baker, Chairman.....	Alabama
Charles H. Goodrich.....	New York
George P. Johnston.....	Wyoming
Virgil E. Simpson.....	Kentucky
Thomas F. Thornton.....	Iowa

REPORTS OF OFFICERS

Wingate M. Johnson, Chairman.....	North Carolina
J. Newton Hunsberger.....	Pennsylvania
R. L. Sensenich.....	Indiana
Joseph F. Smith.....	Wisconsin
Guy W. Wells.....	Rhode Island

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Floyd S. Winslow, Chairman.....	New York
Clyde L. Cummer.....	Section on Dermatology and Syphilology
Arthur C. Morgan.....	Pennsylvania
McLain Rogers.....	Oklahoma
Joseph F. Siler.....	United States Army

CREDENTIALS

B. F. Bailey, Chairman.....	Nebraska
J. W. Burns.....	Texas
Blase Cole.....	New Jersey
William H. Myers.....	Georgia
Deering G. Smith.....	New Hampshire

MISCELLANEOUS BUSINESS

J. D. Brook, Chairman.....	Michigan
Herbert L. Bryans.....	Florida
Walt P. Conaway.....	New Jersey
Charles S. Skaggs.....	Illinois
C. W. Waggoner.....	Ohio

EXECUTIVE SESSION

Thomas A. McGoldrick, Chairman.....	New York
J. H. Cannon.....	South Carolina
E. H. Cary.....	Texas
E. F. Cody.....	Massachusetts
John H. Fitzgibbon.....	Oregon

COMMITTEE ON REAPPORTIONMENT

Walter F. Donaldson, Chairman.....	Pennsylvania
H. B. Everett.....	Tennessee
Charles J. Whalen.....	Illinois
Olin West.....	Secretary
Nathan B. Van Eiten.....	Speaker, House of Delegates

SERGEANTS AT ARMS

Holman Taylor.....	Texas
Howard C. Frontz.....	Pennsylvania

Committee to Propose Amendments to By-Laws
Providing for Fitting Recognition to Fellows
Rendering Distinguished Service in
Science and Art of Medicine

H. H. Shoulders, Chairman.....	Tennessee
John W. Amesse.....	Colorado
J. D. Brook.....	Michigan
J. F. Hassig.....	Kansas
Grant C. Madill.....	New York

Address of President Charles Gordon Heyd

The Speaker resumed the Chair and presented the President, Dr. Charles Gordon Heyd, New York, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

A philosopher observing the passing pageant of social change might well exclaim "Cursed be the social lies that warp us from the living truth." He would listen to a melody of chaos, with embattled nitwits wishing to destroy the cultural and physical progress of the last fifty years by a futile attempt to remodel human nature and incidentally remake the entire field of medical practice to his heart's content.

It is opportune that we should survey the situation. At the outset I grant that there are certain areas in the United States where there is what may be termed inadequacy of medical service. There will remain such inadequacies of service until the enlightening benefit of education, until there is an increase in nutritional standards, until good roads and long continued health education have rendered it possible to bring the intellectual and cultural level of the people living in these areas to a social plane that makes modern medicine possible of application. Medicine today is doing its social duty in a continuous and unostentatious manner but with a constant increment of effectiveness in improving the health of all of our people. The mortality and morbidity statistics give the final answer as to the effectiveness of the medical service. In the last thirty-five years the crude mortality has diminished; better babies are being born, individuals are living longer and many diseases have almost completely disappeared or are being brought into a numerical condition of an irreducible minimum. As contrasted with this we have the violence from the fast tempo of American life, which has killed yearly more and more of our citizens until death by accident is fifth in the causes of death.

In the broad social sense, conditions of housing are improving, hours of labor are being reduced, the wages of the laborer are being increased and nourishment is becoming more adequate and more scientific. In brief, the personal and environmental conditions of life are improving everywhere in the United States.

The profession, under the give and take of free competition in medical practice, has produced insulin, liver therapy and vitamin nutrition, has developed orthopedic, cancer and restorative surgery, has made diagnosis precise by advances in x-rays and instrumentation, and has evolved effective therapy with x-rays and radium—in brief, has been so prolific in useful discoveries that medicine is to be rated well in advance of any of the physical sciences.

There are, however, on the medical horizon certain provocative questions. Organized medicine is not immune from critical study and must find the answer to certain impending changes in our medicosocial organization. The abstract question "Has an individual a claim on government for personal medical care?" should be answered. Governmental agencies control education, influence public opinion, have the major portion in the management of widespread health movements, and with legislative enactment control hours of labor, child labor and conditions under which labor works. It would be apparent that medical care is a problem not alien to the purpose of government, for the health of its citizens must be one of the paramount considerations of the state.

Society may be divided into four main groups. This division is based on their economic status: 1. The rich: The members of this class are quite capable of paying for medical services; they constitute great economic power but little, if any, political power. 2. The salaried group, as distinguished from wage earners: These persons are able to buy medical services under the ordinary conditions of a proper economic system; they are not politically powerful and as a rule are not organized politically. 3. The wage earners: This group constitutes approximately 27,000,000 individuals and earned \$34,485,000,000 in 1929. They represent the acme of political power; they may and usually are organized by astute politicians for the furtherance of machine politics and class privilege. Under normal circumstances they can pay for ordinary sickness, but their financial position is in jeopardy in the presence of a sudden, emergent, catastrophic illness. 4. The indigents: An indetermined number

who by reason of poverty, maladjustment and diverse reasons, cannot pay for medical services at any time under any economic system.

Four factors contribute to the medicosocial disabilities of the present day: (1) the utilization of power in the production and maintenance of machines, (2) the crowding of the world by the biologic phenomena of accelerated production, (3) the immense accumulation of scientific knowledge, and (4) the tremendous upsurge and steady rise in average education.

It is not compulsory health insurance or state medicine that will destroy free and competitive medical practice; it is an extension of institutional medicine for which the state will provide the funds. The hospitals under the full time, paid physician are in spirit and many times actually practicing medicine. These same hospitals are confronted with a diminishing income. In 1929 the voluntary hospitals received \$130,000,000 from private benefactors and in 1935-1936 received \$24,000,000, a decrease of 80.9 per cent. The hospital system faces no new givers of large funds, and hospitals have had the income from their investments reduced. It is not improbable that the state will enter into this picture in order to maintain the existing hospitals, clinics and health centers already set up. This will certainly entail political control of the greatest source of medical practice and it requires but little imagination to anticipate that the second step in this program will be the control of the medical schools.

Many prophets in high office have been preaching the pernicious doctrine that the high cost of medical care is due to the doctors. This requires some analysis. The statistics of outpatient departments show that more and more people are availing themselves of free dispensary medical service. The percentage of increase in free dispensary service is describing a curve with a greater acceleration than the increased rate of population. Obviously, if this is carried to its final conclusion everybody would eventually be free dispensary patients. More and more physicians will of necessity become salaried physicians, which by and of itself is neither good nor bad. The fact that a doctor has a salaried position lessens his overhead and in many cases takes away from and keeps away from him his greatest source of worry; namely, the overhead in slack times.

It is not good public policy to ask the doctor to contribute largely of his time, strength and health in rendering free services in the hospital or in the community, when every other person who comes in contact with the sick is paid adequately for the services rendered.

It is apparent that solidarity of the medical profession is under constant sabotage by groups on the fringe of the profession. Furthermore, we have within the profession certain pressure and compulsion groups that are endeavoring by indirection to set up alien forms of medical service. This fractionalization of medical organization, or, better, fragmentation, has done much to implement the enemies of the profession. It would seem wise that we reexamine and reappraise our medical policies. There is literally a tower of Babel apparently speaking for the profession. It has often seemed to me that Elbert Hubbard's beautiful brochure "Essays on Silence" would be a splendid gift to some of our professional planners. You will remember that this particular brochure has seventy-five pages without a word on them. The House of Delegates of the American Medical Association is rightly the voice of the organized medical profession and should speak in unequivocal terms what it considers the best form of medical practice for the citizen of the United States. Your Trustees have been vigilant in anticipating some of the various attacks made on the medical profession. They have fulfilled the spirit and substance of your instructions in a most praiseworthy manner. In like measure *THE JOURNAL* has been particularly alert and forceful in interpreting your actions to the membership. Tremendous changes have taken place in our conception of society, and life is moving forward with a constantly accelerated momentum. Our final objective or destination may be obscure, yet change there will be. Organized medicine is the spirit of service and is founded on loyalty to traditions. It is in essence a fidelity to an ideal. It makes for continuity of effort and endows organizations with character. Medical progress is not a static principle but a dynamic concept of service to the community for the taking care of the physical and mental condition of society. By constantly accepting the advances in science, organized medicine has accelerated

the health of the people and reduced the measure of illness. Organized medicine believes that it is by this dynamic quality of scientific progress that good medical practice has been given and will continue to improve, and that fundamentally the question is quality of medical service and not the cost of medical service.

There are a number of major problems to be solved. The question of medical indigence—a condition untouched and unanswered in all systems of compulsory health insurance—is constantly before us and should engage our serious consideration. Are we prepared to accept the following propositions?

1. That every practitioner believes that the proved indigent is entitled to medical services free of all charges and that the cost of this service should be paid by taxes levied on the general population.

2. The principle that indigence is a local problem and should be handled in the area in which it arises.

3. The extension of medical services to the indigents in their homes and the doctors' offices with remuneration to the physicians on a capitation basis under the direction of the county medical society, all free services to indigents to be rendered by the physicians or outpatient department of the hospital within the geographic or regional zone in which the indigent resides.

4. The certification of indigents, fairly, sincerely, honestly and sympathetically by the application of standards of eligibility, by central bureaus under the department of welfare, with proper representation from the county medical society. It should not be the function of the outpatient department to pass on the validity of indigents, nor should they admit for free services those that are not in truth indigents.

5. A medical census of the indigents, to learn what our load is and how to take care of it. There should be devised a positive means of identification to prevent padding of the lists.

6. A limitation of the number of patients that may attend any one clinic. Since it is claimed that there is no profit in clinic and outpatient department services, there should be no desire for a hospital to increase the number of outpatients beyond its capacity to take care of them. To save valuable time, with the economic loss, clinics could be run with a limited number and on an appointment basis.

7. The payment of a fair remuneration to all physicians working in outpatient departments or giving medical services to the indigents in their homes. This remuneration must not be so low as to bring with it an inferior medical practice and the palliative bottle of medicine. It should not be too high. A fair average can be worked out and still maintain the best qualities of scientific medicine. In the planning of the details of this service it might seem wise to set up a special subdivision of activity under the auspices of the county medical society.

8. The unequivocal opposition to all forms of compulsory health insurance. Insurance schemes tend to relieve the individual of his own responsibility and to increase the prolongation of illness. In short, under an insurance scheme it is profitable for a person to be sick.

9. It is apparent, without wishing to be invidious, that there are, medically speaking, backward areas where the paucity of population and physicians, or its low level economically, or its extreme congestion and poor living conditions render it impossible to provide a fair degree of medical services under the present personal remuneration basis. In such areas it is desirable for the local or state health agencies to set up a laboratory service in chemistry, pathology and bacteriology for the use of practitioners in that area, these laboratories to be established on a regional or geographic basis and with and by representation by the local county medical unit and/or the state medical society. This service is to be a purely diagnostic laboratory service for physicians only, such as exists in our more forward looking states with regard to Widal, Wassermann and other diagnostic procedures. No treatment in any form should be provided under this set up.

10. The studies on rural medical service should be continued and general principles and policies elaborated for consideration by the House of Delegates. The employment by the government of medical personnel for services in unusual or geographically remote areas has been recommended.

11. What are we to do with "catastrophic illness?" By catastrophic illness I mean the emergency that is expensive and for which no ordinary family can budget. Its emergency character, its expense and the necessity for immediate help render it an

important item in the conception of any medical service. It probably represents from 8 to 10 per cent of acute illness at any one time.

It seems to me that these are not unattainable objectives but can be brought into being by a mutual consideration of the problems between the various parties interested and organized medicine.

A recent event in regard to health insurance in British Columbia is not without its significance. Agitation for such insurance began to take form when a royal commission on state health insurance and maternity benefits was appointed in April 1929. The final report of the commission, published in 1932, recommended "suitable compulsory health insurance including maternity benefits." The British Columbia Medical Association and the Canadian Medical Association laid down the principles that they felt should be included in such a law. Assuming the acceptance of these principles, a majority of the members of the British Columbia Medical Association in 1934 stated that it would approve a plan. In 1935 a plan was proposed by a provincial committee, which included all these principles and was generally accepted. When the time came for enactment, it was discovered that the government refused to assume any financial responsibility or to appropriate any money for the care of the indigent and the low income classes. Opportunity was given for thorough consideration of these objections and of the law as a whole, and then the 635 members of the College of Physicians and Surgeons of British Columbia were questioned as to whether they were willing to serve under the law. As has already been reported in *THE JOURNAL*, votes were received from 632, of whom 619 voted against the plan and thirteen in favor. Since it was manifestly impossible to introduce any system of sickness insurance against such a united front of the physicians, the Premier issued instructions to postpone operation of the law.

There rests on the medical profession one obligation that is superlative to all others. We have received from the past the splendid edifice of modern medicine. It is our natural duty to hand that on to generations yet to come, with the splendid spirit of science and the spirit of loyalty. The ranks of organized medicine must stand fast, must speak unanimously with one resonant voice, so that medicine shall be free to explore the unheralded realms of science and march forward with increasing effectiveness. Hundreds of years ago it was stated that "where there is no vision, the people perish."

Address of President-Elect J. H. J. Upham

The Speaker presented the President-Elect, Dr. J. H. J. Upham, Columbus, Ohio, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

In the past twelve months the opportunity and privilege have been given me to attend sessions of the component state societies of the American Medical Association and allied medical society meetings in seventeen states—from Vermont to Utah, from Wisconsin to North Carolina—thus gaining more or less a cross-section view of our medical organization, medical practice and the desire for the acquiring of self improvement in medical information in these areas.

In such an itinerary one is greatly impressed by the great differences in the area of many of these states, the variation in the population and the prevailing types of occupation as they affect the medical profession and medical practice.

Some relatively small states are densely populated. They have large cities with manufacturing and mercantile interests, and considerable tributary suburban areas with relatively smaller rural population. In such states one sees all types of medical practice, industrial, urban, suburban and rural, but even in the last named few areas are so isolated as not to be in fairly convenient reach of hospital and laboratory aid. Therefore, medical organization is relatively simple and is efficiently carried on; medical practice is maintained on a fairly high average plane, and the interest in self improvement in medical information is correspondingly evident.

Other states may be four or five times as large, with populations one tenth as great. Some of these have huge stretches of prairie or mountainous areas with resulting isolation of the

widely scattered inhabitants largely engaged in agricultural pursuits. In these areas the difficulties of maintaining medical organizations and providing even relatively adequate medical care may readily be seen. The progress that is being made and the interest in medical activities and medical progress are gratifying when one notes the relatively high percentage of membership attendance at the annual state meetings in spite of the often considerable sacrifice of time and effort entailed.

One is further impressed by the number and variety of other conditions that affect the medical profession and medical practice, which bring many and varied problems peculiar to America and different from practically all other civilized countries. Some of these are the diversity of climatic conditions from Maine to California and from the Dakotas to Florida. Largely because of these, together with topographic accessibility to foreign countries, there have been definite trends in immigration, causing different racial mixtures in various sections. To realize this in general terms, it is only necessary to mention the large element from middle and southern European countries settled in our metropolitan cities of the East, the influx from northern Europe and especially the Scandinavian countries to the Northwest, the immigrants from the Orient and Mexico in the West and Southwest, and the large Negro element in the South. From these topographic and racial conditions alone one may see the insurmountable obstacles to providing a standardized practitioner or a single standardized type of medical practice.

We are rather prone to pride ourselves on our educational system in this country; on our number and excellence of high schools and colleges. It is probably true that illiteracy is relatively low and that cultural and technical education is on a high average plane. When, however, we note everywhere the great number of parasitic pseudoscientific healing cults prevailing today and the flourishing "patent" medicine and proprietary nostrum companies, and see highly educated people following after these false gods and patronizing charlatans, we become pessimistic and wonder whether intelligence has kept pace with education. The explanation would seem to be either that there is a too general lack of information on the part of the public in health matters and a consequent failure of appreciation of modern scientific medicine, or that too many have experienced failure of relief from too large a proportion of medical practitioners, or perhaps both of these reasons.

Finally, as one travels over the country one is impressed by the feeling of unrest in medical circles, manifested in the frequent discussions of the socialization of medical practice, the resentment against the charges of the prevailing inadequacy of medical practice, and medical responsibility for the alleged excessive costs of medical care.

At present the best minds in our organization are unceasingly considering the latter widely publicized questions, and information is being gathered and careful studies are being made of experiences in other countries as well as in our own. Those familiar with the ideals and policies of the leadership of the American Medical Association know full well that these policies aim toward evolution rather than revolution.

Our association is not reactionary nor is it struggling to maintain the status quo merely because it is the status quo. Rather, it is resisting with all its power the suggestions of theorists and experimenters of any and all schemes which would impair or cause deterioration of the quality of medical practice in this country.

In the meantime, two lines of organization activities might engage the attention of this body: first, the subject of the continued education of our members after graduation, and, second, the better informing of the public with regard to modern scientific medicine and health matters in general.

It may be said, and said truly, that both of these are already a well established part of the activities of the Association. The Council on Medical Education and Hospitals has done a monumental service in the grading of hospitals for the training of interns and stimulated the medical growth of the attending physicians by the requiring of monthly meetings of the staffs. The general organization plan of the Association requires meetings of the component county and state societies. From a questionnaire sent out to representative areas of the country, the attendance at these is relatively excellent. That these are

not enough to satisfy the urge of the general profession for medical information, however, is shown by the fact that there are listed in the latest edition of the American Medical Directory 140 additional special and sectional societies holding at least one or more meetings a year.

The number of medical society meetings has become burdensome, and a study of the programs shows a lack of systematic planning. It would seem opportune to recommend to the Council on Medical Education and Hospitals that its next logical step should be to survey the present conditions, and particularly to study the possibilities of the traveling postgraduate courses organized already in some states through the cooperation of the state associations and medical colleges in those areas with the hope of bringing modern medical developments to practitioners living in the more isolated areas, who are unable to attend meetings often because of lack of accessibility to the usual meeting places.

With regard to the education of the public, the work of the Bureau on Health and Public Instruction is greatly to be commended, and its work is well supplemented in some states.

It would, however, be a great aid in extending this increasingly essential activity if this body would draw the attention of all the component societies to the almost overwhelming mass of misinformation and false statements constantly issuing through the radio, through the daily press and through some so-called popular magazines, directly inspired by antimicrobial sources.

I would suggest for your consideration the thought of the advisability of recommending to the Board of Trustees the calling of a conference of representatives of the component state societies to consider this subject, or the making it a special topic for consideration at the next Annual Conference of State Secretaries, in the endeavor to stimulate a greater interest and seek some general country-wide program of systematic effort correlated with that of the national organization.

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

Report of the Board of Trustees

Dr. Rock Sleyster, Chairman, presented the report of the Board of Trustees, and stated that at a meeting of the Board, June 6, a resolution was unanimously adopted recommending to the House of Delegates that a Council on Industrial Health be established. The report of the Board of Trustees was referred to the Reference Committee on Reports of Board of Trustees and Secretary, except those portions of the report referring to the Bureau of Legal Medicine and Legislation, to the Bureau of Medical Economics, to the Bureau of Health and Public Instruction and to the report on Occupational Diseases and Industrial Medicine, which were referred to the Reference Committee on Legislation and Public Relations; those portions of the report referring to a National Department of Health and to the Extension of Medical Service to the Indigent, which were referred to the Reference Committee on Executive Session, and that portion of the report concerning the Motion Picture on Syphilis, which was referred to the Reference Committee on Hygiene and Public Health.

Address of Colonel W. W. Evans

The Speaker introduced Colonel W. W. Evans, representative of the American Bar Association, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates of the American Medical Association:

At this moment I feel entirely inadequate to discharge a duty which was suddenly wished on me yesterday afternoon at a time when I had just thought to recover from the conflicts and the assaults of a body of brother lawyers whom I essayed to lead in their annual meeting.

Two days of searing conflicts marked our efforts, and I thought on Sunday that I would rest and refresh myself, and

my only justification for appearing here today is that this may afford you a little opportunity of rest and refreshment from committee reports.

I come here under more or less false auspices because in the first place I wear a badge to which I am not entitled. I am not one of those medicolegal gentlemen who practice not only in the courts but on their fellow men, nor am I an ex-president of the American Bar Association. Had my parents wished on me the name of Charles as a Christian name, and the name of Hughes as a surname, and had I been able to wish on myself a glorious growth of hirsute ornaments and give me a cerebrum and a cerebellum which would do justice to a Chief Justice of the United States Supreme Court, I might have been able to fill that appellation.

I only hope that your Secretary may be as excellent a prophet as he is poor as a historian. However, I do come to you with a state of almost innocuous desuetude—I have been stewing in my own juices for the last hour, and all of the poisons which have been generated in the strife of the legal meeting have more or less come from within me.

But it is indeed a pleasant duty which I have to discharge this morning. I must say that I had little expected to address you on the close relationship of the American Bar Association and the American Medical Association.

In the few brief days that I spent in the legislature of New Jersey I had the opportunity of coming in close contact with the medical profession at a time when the medical profession of New Jersey was gravely concerned over its future by reason of the inroads of those who were known as chiropractors, chiropodists and others who sought to practice medicine. After they had met defeat after defeat at the hands of the legislature by a reasonable wall of propaganda that had put the medical profession in a very awkward and embarrassing position, they were said to be the monopolists of the medical field. However, while I had been against the medical profession by reason of the onslaughts of my own brother-in-law, who is a distinguished member of the profession and who sought to convert me by severe strictures on my intelligence, I finally was waited on by four very distinguished members of the medical profession. I think one of them was a surgeon of international reputation, Dr. Harris, a Dr. Todd, who was a general practitioner of very fine reputation in the community, Dr. McBride, who later became the president of the state Medical Society of New Jersey, and one Dr. McCoy, another distinguished surgeon. Those men labored with my youthful intelligence for somewhat like three hours before they began to convince me of the error of my ways, and they showed me by convincing proof of the extent to which our chiropractic brethren had transgressed the limits imposed on them by law, and by reason of that fine approach, for which I give the medical men great credit, they converted me, and I in turn converted a number of the members of the legislature, so that an adverse decision was changed into one that overwhelmingly passed the medical legislation of that year and put the other boys in their place.

From a background such as that, I conceived a very sympathetic interest in the medical profession, and since that time, by reason of representing litigated interests, I have been called on to expend large sums, or reasonable sums, I should say, in the retention of proper medical services by way of expert testimony, and I have also been thrown into that field which called for expert advice with respect to the retention of a field of experts and the reduction of one expert which hasn't met either with the approval of the medical profession or of the legal profession by reason of the fact that it seemed to deprive the medical profession of great emoluments.

Those things have given me a deep appreciation, so when I accepted this assignment I did so with great gratification.

I wish to convey to you at this time the heartfelt appreciation of the American Bar Association for the fine collaboration evidenced by the members of the American Medical Association. You have our common problem, you have a problem which seeks the socialization of medicine; we have a problem which seeks the socialization of the American Bar Association. We haven't the problem that you have, and that is that you have a very adequate reserve and a very splendid treasury which might prove to be a ground of assault by certain socialistic influences which are seeking to level all of those who are in a

somewhat better pecuniary position than the others, so that you may ultimately be reduced to the status of the American Bar Association financially, but I hope that day will never occur, because I believe that with the union of these two great professions and with our desire to bring home to the public the necessities of the individual initiative and the individual advancement and of the opportunity of the young man, no matter how small his stature may be, no matter how unable he is to get the great benefits derived from the educational facilities, those opportunities may still be afforded the young man, and the young man may be able to rise to those great heights which are open to the whole field at the present time.

We have our common problems, and we are laboring with them sympathetically with you, and I trust that at all times you may feel free to consult with the American Bar Association, knowing that you have a sympathetic haven for your problems which have to do with the legal profession and that you may receive there that fine measure of intelligence which your problems ought to receive.

I thank you very kindly.

Report of the Judicial Council

Dr. George Edward Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Amendments to Constitution and By-Laws.

Report of the Council on Medical Education and Hospitals

Dr. William D. Cutter, Secretary of the Council, presented the report of the Council on Medical Education and Hospitals, together with supplementary reports, which was referred to the Reference Committee on Medical Education:

SUPPLEMENT A. REVISION OF STANDARDS FOR SPECIAL EXAMINING BOARDS

Four years ago at the Milwaukee session a resolution was adopted authorizing the Council on Medical Education and Hospitals to give its approval to such special examining boards as should comply with and conform to standards to be formulated by the Council.

A year later, at Cleveland, an outline of these standards for an acceptable board had been approved by the Council and was submitted to the House of Delegates and ratified, and has been in effect since that time. One of the items in this sheet of standards had to do with the period of training to be required of candidates for certification by these boards. It was realized that a period of five years would call for more intensive study and more opportunity for study than was then in existence, but it was hoped, by notifying all who would be interested that this period of training was required before the candidate would appear before a board, that better opportunities and more opportunities for training would be provided, which has been the case. It is still true, however, that adequate opportunities for graduate study for all of those who are seeking to qualify themselves as specialists are not yet available.

It is also true that there is not yet complete agreement and uniformity with regard to the application of this five year period of training for specialists. The Council has, therefore, suggested that this outline of standards for special boards be amended so that the effective date of this particular educational requirement be advanced from Jan. 1, 1938, to Jan. 1, 1942, in the expectation that during this four year period better opportunities for study and training will be provided and also that complete harmony and unanimity of opinion may be reached with regard to the necessity for such a period of training in connection with all the specialties.

Another item is suggested for your consideration and approval, having been recommended by the Council on Medical Education and Hospitals. This has to do with the credentials of men whose education has been obtained outside of the United States and Canada. The Council on Medical Education and Hospitals has been able to study, to keep in touch with and to grade the medical schools of the United States and Canada. We have no information concerning the character of education offered students in medical schools in other lands.

In order that there should be some guarantee that candidates who come before these special examining boards, if they present

credentials from other countries, have received adequate training in the fundamentals of medicine, it was suggested that such candidates be required to pass parts 1 and 2 of the National Board of Medical Examiners, which would constitute a uniform requirement for all such candidates coming into this country. The Council has approved of that revision of these essentials, and submits it now to you for your consideration.

SUPPLEMENT B. SURVEY OF MEDICAL SCHOOLS

A survey of medical schools which has been conducted by the Council during the last two or three years is briefly mentioned in the report which you have in your hands, but it was felt that we should give to the House of Delegates at this time a more detailed statement of the procedure, methods, findings and results of this survey, which is being distributed to the House.

SURVEY OF MEDICAL SCHOOLS

Thirty years ago the Council on Medical Education published the first classification of medical schools. Now it has just completed a comprehensive resurvey of the undergraduate medical course in the United States and Canada. The contrast between present conditions and those of a generation ago is too striking to pass over without notice. At the time the Council was created, most of the medical schools in this country were frankly proprietary institutions, and university affiliations, where such existed, were tenuous or merely nominal. Medical sciences, for the most part, were taught by practitioners without special training. Laboratories were inadequately equipped and laboratory work poorly supervised. Bacteriology and biochemistry were just being introduced into the curriculum. Embryology was scarcely recognized and the study of anatomy was purely descriptive, with more emphasis on memorizing the textbook than on careful dissection with correlation of structure and function. Clinical teaching consisted almost exclusively of lectures and demonstration clinics without personal contact between student and patient. At Johns Hopkins, it is true, Dr. Osler had introduced the British system of clinical clerkships, but other schools were slow to comprehend the merit of this method of instruction.

Since the publication of the Carnegie Report in 1910, the improvement of medical teaching in this country has been phenomenal, unparalleled. A hundred low grade schools have merged with others or dropped out of existence. Entrance requirements have been raised to at least two years of college work. Trained teachers have been provided in the laboratory subjects. In the clinical branches, dispensaries and hospitals are recognized as essential teaching facilities, and a clerkship, which is the modern form of apprenticeship, appears in almost every curriculum. Postmortem studies correlated with clinical studies are much more widely employed.

Progress along these lines, however, has been neither uniform nor continuous. Plans for development were interrupted by the war, and after the war there was necessarily a period of readjustment. Because of the creation in 1925 of a "Commission on Medical Education" with ample funds at its disposal, the supervision of the Council was, for a period, somewhat relaxed. It soon became evident that there was need for a thorough-going study of the aims and methods of medical education, and in 1933 the Council addressed itself to this task.

Some features of the survey have already been discussed by Dr. Wilbur (*THE JOURNAL*, March 6, 1937) and Dr. Weiskotten (*THE JOURNAL*, March 27, 1937) but it seems appropriate at this time to make to the House of Delegates a more formal report of the Council's activities in this connection. After all the recognized and two unrecognized schools in the United States and Canada had been visited, the Council analyzed the reports of the schools, the comments of the inspector, and all other available material. For the purpose of comparative study, ninety-six items were chosen and the schools arranged in an order of excellence with respect to each of these criteria. The results were then plotted on a chart in accordance with the procedure recently adopted by the North Central Association of Colleges and Secondary Schools. A pattern map, so constructed, has already been sent to each of the four year medical schools in the United States and a similar report will shortly be furnished to the Canadian schools and the so-called

two year schools. A sample of these maps may be seen at the booth of the Council, No. 649, in the Scientific Exhibit.

During the progress of the survey the Council has discovered in certain institutions conditions so unsatisfactory that it was deemed necessary, in the interests of prospective medical students and of the public, to remove them from the Council's approved list. Others were placed on probation. Still others were warned of deficiencies and were granted a period of grace during which their shortcomings might be corrected. The Council's influence, applied in these several ways, has already produced striking results. A number of schools have completely reorganized and have made fundamental improvements in student and faculty personnel. They have also secured more adequate financial support. If nothing more were to be accomplished by the survey, these changes alone would justify the Association's expenditure of time and money.

Among the defects noted by the Council may be mentioned the lack of a sound type of university control. In some cases the university affiliation is merely nominal and the medical school derives little or no benefit from the relationship. In some instances, on the other hand, the university, in the supposed interest of unity, sets up departments in which the interests of other groups are merged with those of medical students, to the detriment of the latter.

In their organization the medical schools run the gamut from the extreme democracy of faculty control to monarchical control by the dean. It may be said, however, that the schools which have shown the greatest development are those which have an efficient dean who is able to devote himself unreservedly to the upbuilding of his institution.

Probably the most important factor in determining the output of any school is the character of the input. More and more it becomes evident that a poor environment, while it may retard development, cannot ruin a really good intellect, and that, conversely, even the very best school cannot make a successful student or practitioner out of an inferior mentality. The problem of the selection of students is therefore one of the most important, if not the most important responsibility of any medical school. Only 12 per cent of the medical students now admitted have had less than three years of college work but it cannot be too strongly emphasized that, in judging the preliminary education of a candidate, quality is more important than quantity and that uniformly high scholastic attainment is a better guaranty of success than any number of "units" or degrees. The extremely rapid advances now being made in the field of chemical physiology and the rapidity with which these discoveries are finding clinical application may render it desirable to raise the minimum requirement for entrance to three years and to exact a more thorough training in organic and physical chemistry.

The curriculum requires, of course, constant readjustment. In this process of adaptation some schools lag behind, especially in the continued emphasis on didactic teaching, by means of lectures, quiz, and demonstration clinics. Bedside teaching in hospital wards demands more teachers and more time, as well as more ample clinical material, but the superiority of the results cannot be questioned. In arranging courses, some schools follow the block, or concentration, system. In its extreme form the student devotes himself exclusively to one subject until it is finished and then takes up another. Happily, few schools carry it so far. Generally speaking, however, there is a tendency, especially in the larger schools, to split the program into a considerable number of units, following a variable sequence, which are independently accredited. At the opposite pole, the French universities begin clinical teaching in the first year and carry it concurrently with the laboratory courses for several years. Somewhere near the middle is surely the best road. There is difficulty in making room for new subjects in the curriculum. Medical science advances rapidly, and the knowledge and skill required of a practitioner is vastly greater today than it was twenty years ago. The schools seem to feel that four years plus an internship is all the time the student can afford to give to his professional training. Is there any solution of this dilemma? Some schools have already found a way by utilizing a substantial part of the summer vacation. Some of the new subjects clamoring for attention are psychiatry and its broader aspect, mental hygiene; economics and

sociology as applied to the practice of medicine; industrial medicine and surgery; fractures and other traumatisms, the ever increasing concomitants of automobile traffic; physical therapeutics, a field which until the war was left largely to quackery; endocrinology and organotherapy, and medical jurisprudence in its broader aspects. The physician who, in the next two decades, will satisfactorily discharge his obligations to society must have more than a cursory acquaintance with all these phases of medicine. Diagnosis and treatment are being transformed under the influence of such new developments as radiology and immunology.

In determining the quality of the work done in an institution, the qualifications of the faculty are, next to the selection of students, the factors of greatest importance. At the time of the Council's first survey of medical schools the need of trained teachers was emphasized. Unhappily, the phrase "full-time" was used to differentiate those who chose teaching as their profession from the practitioners who engaged in teaching as an avocation. The important distinction, of course, is not in the time element but in the training, ability and interest of those who constitute the faculty. In the laboratories, standards of personnel have been greatly advanced; but in the clinical branches the controversy still rages over the merits and the functions of "full-time" and "part-time" men. The question cannot be answered by a time clock. It concerns the training experience and, above all, the inherent interest of those who teach. Obviously the man who assumes responsibility for directing a clinical department such as medicine or surgery must devote to his academic duties much more than a few hours a week. On the other hand there is an increasing weight of opinion supporting the view that the teacher who completely renounces the experiences of private practice loses something of value to his students as well as to himself. In medicine, as in other departments of the university, the professor should be a teacher by vocation and should share with his colleagues the same academic responsibilities and liberties. Another problem of growing importance concerns the increasing numbers of teachers in the preclinical branches who do not have a medical degree. Individuals may readily be cited who have been conspicuously successful as teachers of anatomy, chemistry and other subjects who have no formal training in medicine. As a general rule, however, it is our conviction that those who have enjoyed a clinical experience as students and interns will make better preclinical teachers than those who have not. In analyzing the training of those who hold responsible teaching positions it is disconcerting to find that some of our best known universities permit candidates for advanced degrees to earn them concurrently—that double credit is allowed for the same period of study. It would seem that, if graduate degrees are to have any worth-while significance, this practice should be abruptly discontinued.

With the best of faculty and the best of students medicine cannot be taught without patients, and one of the most serious problems confronting medical schools today is the securing of clinical material, adequate in kind and amount, under proper university control and readily available for teaching. For the university itself to own and maintain such facilities entails an enormous financial burden. Without such ownership the medical school is dependent on such affiliations as it can negotiate with tax-supported hospitals or those privately endowed. In the Northeastern section of the country, large endowments have accumulated and there are instances of conspicuously satisfactory affiliations between universities and private hospitals. In the Central and Western portions of the country endowed institutions are rare, and greater dependence must therefore be placed on governmental institutions with all the inherent dangers of political intervention. If a school does not own a teaching hospital it should at all events secure the right to nominate the attending staff in those services which are used for purposes of instruction. As to the minimum number of patients needed for satisfactory clinical teaching the Council has as yet no figures, but it is hoped that in a further report some light may be thrown on this subject.

So far as physical facilities and equipment are concerned, the medical schools are well off. During the last decade enormous sums of money have been spent, not always wisely, on building for laboratories and hospitals, so that there are very few schools

which lack an adequate physical plant. In spite of this fact, during the depression some schools yielded to the temptation to enlarge their classes and consequently suffered from overcrowding.

In its first survey the Council discovered that schools which depended exclusively on the income from students' fees were unable to meet the prevailing standard, and from that day to this it has become increasingly evident that financial resources other than from tuition fees are absolutely necessary to maintain a satisfactory level of instruction. Such resources may be either endowments or governmental appropriations. Before the depression it appeared that the private institutions were more generously supported. Their status in the next decade would be difficult to forecast. The budgets of medical schools range from \$1,600,000 to \$93,000, the median being \$231,000. Obviously a large school costs more to operate than a small one, but the costs do not vary directly as the number of students. There is also a wide spread in the amount expended for administration, overhead, and maintenance of plant. The Council believes that the best index of the adequacy of financial support is expenditure per student for instruction, and this figure has been developed in the pattern maps sent to each school. It varies from \$3,600 to \$170. The median, which is most significant, is \$535.

Although the time devoted to anatomy has been materially reduced, the teaching of this subject in the leading schools has been greatly improved; gross and microscopic anatomy, and embryology are more closely correlated. Charts, slides, cross-sections, models and x-rays are employed as teaching aids. In some schools, students are encouraged to construct their own models. Functional anatomy and general principles are being stressed rather than the accumulation of a vast amount of minute detail. All schools, however, have not progressed equally in this direction, and considering the country as a whole, the teaching of anatomy leaves a great deal to be desired.

Among the preclinical sciences biochemistry stands out as the subject which, on the average, has attained the most satisfactory level. Paradoxically, it is the subject in which there are the fewest teachers who have a medical background. This should not be construed as indicating that such a background is not desirable, but may be explained by the fact that chemistry is a popular subject and that there is a vast number of graduate students in this field. From among so many it is not difficult to supply the small number of vacancies in medical schools.

Departments of physiology are for the most part well organized. There is manifest a tendency to reduce the time devoted to simple experiments of the muscle nerve type and introduce more observations on intact animals including the human subject. The place of physiology in the curriculum is not yet entirely clear, especially its temporal relationship to biochemistry. In the selection of teachers of physiology, at least, it would seem that a knowledge of medicine and some clinical experience should be more generally insisted on.

Pharmacology, of all the preclinical subjects, is most generally neglected. Of sixty-six schools, barely half have organized independent departments of pharmacology with a faculty consisting of men who have received special training in this field. Since pharmacology is the foundation of therapeutics, such conditions should be promptly corrected.

Under the influence of the rapidly developing sciences of immunology and serology, bacteriology is undergoing a transformation. Experimental methods are more generally employed and less stress is being placed on the classical descriptive bacteriology of a generation ago. The increasing prevalence of so-called tropical diseases gives a new importance to parasitology, with which, in some schools, bacteriology is being combined.

Pathology is definitely recognized as the subject which ties together the preclinical and the clinical sciences. It extends through all the later years of the course. Rapidly it is outgrowing the older conception of descriptive morbid anatomy, and is being closely integrated with clinical medicine. Increasing emphasis is being placed on the study of fresh material and the correlation of the patient's history with autopsy findings. Experimental methods are more frequently used in teaching.

It is evident that pathology cannot be satisfactorily taught if isolated from the clinical departments of the medical school.

Medicine, so-called internal medicine, is the most broadly inclusive of all the clinical branches. It is responsible for teaching the fundamental methods of examination and diagnosis to which are added later the differentiated technics of the specialties. In a few schools the curriculum has been based on a recognition of this fact and the student is given his practical experience in medicine before he enters on a clerkship in surgery, pediatrics or obstetrics. The medical clerkship is also of longer duration than the others because of the greater scope of the subject and the larger variety of diseases covered, and also in order that sound habits of history taking and of physical and laboratory examination may be developed. Unfortunately, owing to large classes, or limited clinical material, this program has not been widely adopted. Too often the student rotates through his clinical assignments in a sequence determined by chance or the convenience of the registrar's office, and may find himself, without previous clerkship, attached to a service in pediatrics. It is doubtful whether this procedure can be justified, even on the ground of necessity.

The better schools clearly recognize the fact that it is not the function of the undergraduate course to train surgeons. Emphasis is placed on diagnosis, minor surgery, and emergency work, including fractures. Major surgery, and especially operative technic, is largely left for the internship and residency. The day when students spend long hours in the surgical amphitheatre is, or should be, past.

The teaching of obstetrics is at a lower level than that of the other major clinical departments. Comparatively few schools offer to their students an adequate practical experience under competent supervision. This may result from a variety of causes, one of which is, undoubtedly, the failure of administrative authorities to provide access to a sufficient amount of clinical material. Another may be the feeling on the part of teachers that the practice of obstetrics should be reserved for specialists and that therefore the ordinary undergraduate does not need much training along this line. Still another may be the fact that in many schools obstetrics is not an independent department but is combined with gynecology. In these circumstances, if the head of the combined department is a gynecologist, obstetrics may suffer.

Pediatrics is fortunate in that public interest in this subject has provided admirable facilities. Special hospitals, dispensaries, feeding stations and well-baby clinics afford a wealth of material most of which is utilized for teaching. In a few institutions there is a strange reluctance to permit medical students to enter the children's wards. In general this department rates well.

Preventive medicine, although of undoubted importance, has not yet developed a clear cut and generally accepted objective, so far as the teaching of undergraduate medical students is concerned. In some institutions a good deal of time is spent in demonstrating the activities of a state or city department of health. In others, students are required to make and report on a sanitary survey, while still others act on the assumption that for the man in practice the most important thing is that all of his daily contacts should be imbued with a realization of the importance of prevention and that this attitude can only be instilled by clinical teachers who exemplify it in their own practice. Further study of this problem is an obvious need.

Psychiatry is another subject which has not yet found itself in the medical curriculum. The old fashioned demonstration clinic of advanced cases is no longer in great favor. In some quarters efforts are being made to introduce a psychiatric examination generally into the study of all patients even though the present complaint may not seem to involve mental derangement. There is a growing demand for the inclusion in the preclinical curriculum of introductory courses in psychology or psychobiology.

Some years ago there was a widespread feeling that practice in the eye, ear, nose, and throat fields should be reserved for specialists and that therefore they should not be included in the undergraduate curriculum. They were to be "kicked upstairs into the graduate school." This process has been carried so far that many recent graduates do not know how to make an examination sufficient to enable them to determine whether a

not the patient needs to be referred to a specialist. The schools should more clearly define their responsibilities in this field.

Few schools are giving adequate attention to instruction in physical therapy. The great benefits which may be derived from this form of treatment have been clearly demonstrated since the war. Every physician should be familiar with the indications for physical therapy and with the results which may be attained by its use.

Report of the Council on Scientific Assembly

Dr. Irvin Abell, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Report of Committee to Propose Amendments to By-Laws Providing for Fitting Recognition to Fellows Rendering Distinguished Service in Science and Art of Medicine

Dr. H. H. Shoulders, Chairman, presented the following report of the Committee to Propose Amendments to By-Laws Providing for Fitting Recognition to Fellows Rendering Distinguished Service in Science and Art of Medicine, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Pursuant to the provisions of a resolution adopted by the House of Delegates at the Kansas City session in 1936 a committee was appointed by the Speaker of the House, composed of Drs. J. W. Ames, Colorado; Grant C. Madill, New York; J. D. Brook, Michigan; J. F. Hassig, Kansas, and H. H. Shoulders, Tennessee, as chairman.

Your committee submits the following as a report of its activities:

Much of the work of the committee has been done by correspondence. As a result of the exchange of ideas some fairly definite conclusions were arrived at. Final considerations were given the matter in a meeting of the committee held in Atlantic City, Sunday evening, June 6.

Our interpretation of the provisions of the resolution creating the committee is that our duties are twofold: First, to consider the proprieties and wisdom of creating some means by which the distinguished services of Fellows may be recognized in a fitting manner other than by election to office, and, secondly, in the event of affirmative conclusions, to prepare suitable amendments to the By-Laws and present them for the consideration of the House of Delegates.

It is the unanimous opinion of the committee that such amendments should be enacted by the House and your committee has prepared some amendments to the By-Laws and submits them as a part of its report.

In this connection it should be stated that it was the duty of your committee to consider this matter in association with the Judicial Council. By correspondence the Chairman of the Judicial Council has been kept in touch with the activities of the committee and has given it every cooperation in the way of wise counsel and advice. At the meeting held in Atlantic City the evening of June 6, the Judicial Council participated in the deliberations of the committee.

PROPOSED AMENDMENTS TO BY-LAWS

Your committee submits the following resolutions proposing amendments to the By-Laws to create a Committee on Distinguished Service Awards and prescribe its duties and to create a distinguished service award:

Resolved, By the House of Delegates of the American Medical Association that the By-Laws of the Association be amended by the addition of a new chapter, Chapter XI, to follow Chapter X, as follows:

CHAPTER XI.—COMMITTEE ON DISTINGUISHED SERVICE AWARDS

SECTION 1. There is hereby created a special committee to be known as the "Committee on Distinguished Service Awards of the American Medical Association."

This Committee shall consist of five members and shall serve for a period of three years, except the first committee, two of which shall be appointed for three years, two for two years and one for one year.

Nomination for the Award may be made by any Fellow of the Association, provided the nomination is made in a manner prescribed by the Committee and not less than two months in advance of the next regular annual session of the Association.

SEC. 2. DUTIES AND POWERS OF THE COMMITTEE ON AWARDS. The Committee on Awards shall make its own rules of procedure not in con-

flict with these by-laws with respect to the performance of its duties, subject to the approval of the House of Delegates.

It shall consider the eligibility of nominees for the Distinguished Service Award of the American Medical Association on the basis of meritorious services in the science and art of medicine and shall submit its findings and recommendations to the Board of Trustees, annually, within a time limit fixed by the Board of Trustees.

In the event that more than five nominations are received, the Committee shall select therefrom a list of not more than five to be submitted to the Board of Trustees together with a brief statement of its findings with reference to each.

The present chapters XI, XII, XIII, XIV, XV, XVI, XVII, XVIII and XIX shall then become chapters XII, XIII, XIV, XV, XVI, XVII, XVIII, XIX and XX respectively.

Resolved, By the House of Delegates of the American Medical Association, that Chapter VI of the By-Laws be amended by the addition of a new section after section 4 as follows:

SEC. 5. TO ESTABLISH A DISTINGUISHED SERVICE AWARD OF THE AMERICAN MEDICAL ASSOCIATION. The Board of Trustees shall create and establish an award to be known as the Distinguished Service Award of the American Medical Association, which shall consist of a medal and a citation.

One Fellow of the Association shall be eligible to receive the award each year and shall be selected in a manner prescribed in these By-Laws.

The Board of Trustees shall consider the merits of nominees for the award recommended by the Committee on Distinguished Service Awards and shall select from the list not more than three Fellows to be balloted on by the House of Delegates. The Board of Trustees shall submit the list of nominees so selected to the House of Delegates for consideration, together with a brief statement of the findings of the Committee on Awards with respect to each nominee.

The House of Delegates shall select the recipient of the award from the list of nominees submitted by the Board of Trustees. The selection shall be by ballot in the same manner as officers are elected. The vote shall be taken immediately after the nominees are placed before the House by the Board of Trustees.

The Board of Trustees is charged with the duty of having prepared a suitable medal and citation each year, and is further charged with the duty of fixing the time and method of presentation.

Report of Committee to Study Contraceptive Practices and Related Problems

Dr. Carl H. Davis, Chairman, submitted by title the report of the Committee to Study Contraceptive Practices and Related Problems, which the Speaker declared would be discussed at the Tuesday afternoon Executive Session of the House.

Preliminary Report of Committee to Study Problems of Motor Vehicle Accidents

Dr. Herman A. Heise, Chairman, presented the following report of the Committee to Study Problems of Motor Vehicle Accidents, which was referred to the Reference Committee on Miscellaneous Business:

At the annual session of the American Medical Association held at Kansas City in 1936, the appointment of a Committee to Study Problems of Motor Vehicle Accidents was authorized by the House of Delegates, and the Board of Trustees was instructed to appoint the committee as now constituted. The Committee met in the Board of Trustees room in the American Medical Association building in Chicago at 10 a. m., March 19, 1937. Members of the Committee present were Dr. Herman A. Heise, Milwaukee, chairman; Dr. Burt R. Shurly, Detroit; Dr. Thomas A. McGoldrick, Brooklyn, and Dr. C. W. Roberts, Atlanta, Ga. Others in attendance were Mr. Richard Thrush, Assistant Director of First Aid of the American Red Cross in place of Dr. Cary T. Grayson, member of the committee, who was unable to be present; Mr. Sidney Williams of the National Safety Council, who had been invited by Dr. West to attend the meeting; Dr. Austin A. Hayden, Chicago, a member of the Board of Trustees of the American Medical Association; Dr. Morris Fishbein, Editor of THE JOURNAL, and Dr. Olin West, Secretary of the American Medical Association.

Dr. West opened the meeting by reading the following resolution on the appointment of a Committee to Study Problems of Motor Vehicle Accidents:

WHEREAS, The street is a battlefield, and thousands of our citizens are killed and disabled by reckless, incompetent and physically disqualified individuals; and

WHEREAS, The medical profession has stood for centuries past for the safeguarding of life and the prevention of injury; therefore be it

Resolved, That a committee of five be appointed by the President to survey and study the problems of motor vehicle accidents and injuries therefrom, and report to the House of Delegates; and be it

Resolved, That an appropriation sufficient to cover necessary expenses be provided for the study.

IMPORTANCE OF TRAFFIC ACCIDENTS

The committee agreed that we can continuously study the entire problem of traffic safety and give our support both as doctors of medicine and as individuals to every sound effort being made for safer roads, safer automobiles, driver education and better legal regulations and their enforcement. However, our present study should be directed particularly to a consideration of those physical and mental defects which account as contributing factors in unsafe driving. The importance of our problem can be better comprehended when we realize that motor vehicle accidents are the principal cause of fatal accidents in the age group of 5 to 64 and that, if the present rate of slaughter continues, one out of every twenty persons in the United States will be injured or killed in a motor vehicle accident within the next five years. An even more startling prophecy is that unless some drastic means of combating traffic accidents is instituted, two out of every three children now living will be injured in a motor vehicle accident in his lifetime.

DRIVER'S LICENSE LAWS

In most states no provision is made for the furnishing of evidence of physical or mental fitness of motor vehicle drivers. This condition is particularly deplorable since the National Safety Council has made available to all states a model driver's license code.

The importance of adequate driver's license laws is shown by a nine years trial. In this time, states having a standard license law have decreased vehicle death rates by an average of 20 per cent, while all other groups of states have increased their death rates, some more than 30 per cent. The committee recommends the adoption of the uniform driver's license law by all states, since this would be an additional factor in traffic safety and would not only give the states some control over the driver with physical and mental defects but would be of additional value in collecting records of the chronic law violators, the reckless, and the "accident-prone." Persons having bad records would be examined for physical, mental or psychologic abnormalities with a view toward correction or possible compensation for the deficiencies, or if this is not possible licenses may be revoked.

EDUCATION IN TRAFFIC SAFETY

The Committee recommends that the American Medical Association sponsor a campaign of education, keeping before the public the importance of physical and mental factors in accidents, including the influence of fatigue, ill health, disturbed vision or hearing, the effect of drugs, carbon monoxide, alcohol and the like. Incidentally, the almost indefinable subject of courtesy appears to be a factor in motor vehicle accidents. The control of a powerful instrument apparently inflates the ego of some otherwise meek individuals to the extent that they lose their appreciation of the rights of others.

ALCOHOL AND ACCIDENTS

The relationship of alcohol to traffic accidents demands further study. It is a surprising fact that the excess in the number of accidents over the expected number as calculated from traffic volume corresponds to the peaks in alcohol accidents as confirmed by chemical examination.

MEDICOLEGAL APPLICATION OF CHEMICAL
TESTS FOR ALCOHOL

Since it is impossible to diagnose drunkenness adequately—drunkenness from the symptoms alone—it is important that the chemical observation of the blood, urine, saliva or breath for alcohol be used to confirm obvious intoxication. The Committee on the Driver of the National Safety Council has agreed that 0.15 per cent or more of alcohol by weight in body fluids is associated with mental and/or physical inferiority and that this figure is therefore valuable in legal cases. It must be understood, however, that much lower levels of alcohol are associated with definite impairment of judgment and particularly of self criticism. Also the attitude of this committee on the subject of alcohol concerns only traffic safety, and therefore drinking is considered only from the standpoint of time and place.

RED CROSS HIGHWAY FIRST-AID STATIONS

The committee wishes to congratulate the American Red Cross for its establishment of Highway First-Aid Stations. This is not only a life-saving measure but is apparently decreasing the numbers of accidents by making drivers conscious of the danger of carelessness.

RECOMMENDATIONS FOR FURTHER STUDY

It is recommended that hospitals aid in the investigation of accident causes from the medical standpoint and that the American Medical Association sponsor a symposium on the various phases of traffic accidents, the results of investigations to be presented at the 1938 session of the American Medical Association. Recommended subjects for further study are Physical and Mental Defects as Factors in Traffic Accidents and Effect of Drugs, Carbon Monoxide, Alcohol, Fatigue, and the like.

Reports of Special Committees

The reports of the Committee to Study Air Conditioning, the Committee on Asphyxia and the Committees on Scientific and Therapeutic Research, as submitted in the addenda to the Report of the Board of Trustees, were referred by the Speaker to the Reference Committee on Reports of Board of Trustees and Secretary.

Report of the Committee on Medicolegal
Blood Grouping Tests

The following report of the Committee on Medicolegal Blood Grouping Tests was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

To the Members of the House of Delegates of the American Medical Association:

The purpose of this committee was to report on the reliability of blood grouping tests when applied in medicolegal cases for the exclusion of parentage and in criminal cases for the individual identification of blood and other stains, with special reference to further legislation relating to blood grouping tests for excluding parentage. The report now submitted contains the conclusions and recommendations of the committee, based on a review of the literature and experiences of its members.

It was found advisable to consider the application of the tests for the exclusion of parentage and the examination of stains separately. It is also necessary to consider separately the classic four blood groups O, A, B and AB, discovered in 1901-1902, and the three types M, N and MN, found in 1928.

NOMENCLATURE

Before proceeding with the question of the forensic application of the tests, a few statements concerning the nomenclature are in order.

The Four Blood Groups.—Three different methods of designating the four groups are in use; namely, the Moss, the Jansky and the International nomenclatures. The relationship between the various designations of the groups and composition of the blood is given in table 1. The existence of two systems of designation by numbers has resulted in confusion on many occasions and has occasionally been responsible for transfusion accidents. Hence the Health Committee of the League of Nations has recommended the adoption of the International Nomenclature, which is based on the agglutinin content of the red blood cells. Practically all scientific and many medical publications use this nomenclature exclusively, and the committee recommends its general use also in hospitals for blood transfusions and in reporting results of blood grouping tests to courts in forensic cases.

The M-N Types.—Depending on the presence or absence of the properties M and N in the red blood cells, three types of human individuals have been identified; namely, type M (individuals possessing agglutinin M but not agglutinin N), type N (individuals possessing agglutinin N only), and type MN (individuals possessing both agglutinin M and N). Individuals lacking both agglutinins M and N do not exist.

To avoid confusion between the types M, N and MN and the blood groups O, A, B and AB the committee recommends that the term "group" be used only when referring to the latter and that the term "type" be used when referring to the more recently discovered properties M and N.

APPLICATION TO THE BLOOD GROUPING TESTS FOR
EXCLUSION OF PARENTAGE

The development of the particular aspect of blood grouping tests as used for the exclusion of parentage falls naturally into two periods, namely, that from 1910 to 1930, in which interest was focused exclusively on the four blood groups, and that from 1930 to date, which has witnessed the application of the three M-N types.

TABLE 1.—Classification and Composition of the Blood Groups

International Nomenclature	Jansky Numbering	Moss Numbering	Cells (Agglutinogens)	Serum (Agglutinins)
O	I	IV	—	α and β
A	II	II	A	β
B	III	III	B	α
AB	IV	I	A and B	—

Application of the Four Blood Groups.—Ottenberg and Epstein in 1908 first suggested the hereditary nature of the blood groups, but their studies were limited to a few families. To von Dungern and Hirsfeld, who made the first extensive study of the heredity of the blood groups in 1910, and to Bernstein, who in 1925 evolved the theory of heredity now accepted by the investigators in the field, belongs the credit for the discovery of the mechanism of the inheritance of the blood groups.

According to Bernstein's theory, the blood groups are inherited by means of three allelomorphous genes, A, B and O. Accordingly, there exist six genotypes, corresponding to the four blood groups, as is shown in table 2. From this theory it can be readily deduced to what groups the children may belong when the groups of the parents are known. Table 3 presents the inheritance of the blood groups under the Bernstein theory.

Table 3 may be summarized in two laws of heredity: 1. The agglutinogens A and B cannot appear in the blood of a child unless present in the blood of one or both parents (matings 1-6 in table 3). This is also known as the law of von Dungern and Hirsfeld. 2. Individuals of groups AB cannot have chil-

TABLE 2.—Bernstein's Theory of the Heredity of the Blood Groups

Phenotype*	Genotype*
Group O	OO
Group A	AA, AO
Group B	BB, BO
Group AB	AB

* Genotype refers to the genetic constitution; this depends chiefly on the genes. Phenotype refers to the actual makeup of the individual; it is determined by the interaction of heredity and environment. In the case of the blood groups, there is no serologic difference between individuals of genotypes AO and AA or genotypes BB and BO, since genes A and B are dominant over gene O.

dren of group O, and group O individuals cannot have group AB children (matings 7-10). This is known as the Bernstein law, since it is the direct result of his theory of the inheritance of the blood groups.

A survey of the literature shows that, in a series of more than 10,000 families with 20,000 children which were studied by a number of investigators from 1910 up to present time, no exceptions to the first law of heredity have been established. Hence the committee feels safe in recommending the application of this rule without reservation.

With regard to Bernstein's law, a series of 4,000 group O mothers with their 5,000 children have been examined, and not one of the children was found to belong to group AB. In addition, more than 600 group AB mothers with almost 1,000 children have been examined and in only one case has there been what seems to be a real exception to Bernstein's theory. In this particular case, reported by Haselhorst and Lauer, the mother belonged to group AB and the child to group O. Therefore the committee recommends that Bernstein's law be applied in paternity proceedings and other cases of disputed parentage

1. Allelomorphous genes determine differences in particular characteristics and are situated on corresponding loci of a homologous pair of chromosomes.

with the following reservation: In cases in which the supposed parent belongs to group AB and the child to group O, or vice versa, it should be stated merely that parentage is extremely unlikely or that parentage is excluded with a high probability, bordering on certainty.

A number of suggestions have been offered to account for the exception reported by Haselhorst and Lauer. Levine attempted to explain it on a genetic basis, attributing the phenomenon to nondisjunction.² Another possible explanation, perhaps, is a serologic one. Thus, Lauer reports that the mother in his case belonged to subgroup A₂B. Hence the child, if it belonged to group A, would have to belong to the more weakly reacting subgroup A₂, unless the father belonged to subgroup A₁ or A₂B.

Application of the Properties M and N in Cases of Disputed Parentage.—As Landsteiner and Levine have demonstrated, the three M-N types are transmitted by means of two allelomorphous genes, M and N (table 4). Under this theory it is evident that bloods lacking both properties M and N should not exist. The fact that, in tests performed up to the present time on almost 50,000 specimens of blood by various workers in the

Groups of Parents	Groups of Children Possible	Groups of Children Not Possible
1. O × O	O	A, B, AB
2. O × A	O, A	B, AB
3. O × B	O, B	A, AB
4. A × A	O, A	B, AB
5. A × B	O, A, B, AB	None
6. B × B	O, B	A, AB
7. O × AB	A, B	O, AB
8. A × AB	A, B, AB	O
9. B × AB	A, B, AB	O
10. AB × AB	A, B, AB	O

TABLE 4.—Mechanism of Transmission of the M-N Types

Phenotype	Genotype
Type M	MM
Type N	NN
Type MN	MN

field, not one individual was found lacking both M and N is strong evidence in support of this theory.

From this theory it can easily be predicted to what types the children must belong if the types of the parents are known (table 5). Table 5 can be summarized in two laws of heredity: 1. The agglutinogens M and N cannot appear in the blood of a child unless present in the blood of one or both parents. 2. A type M parent cannot have a type N child, and a type N parent cannot have a type M child, regardless of the type of the second parent.

These two laws of heredity have been tested by a number of independent investigators. In a series of well over 1,000 families with almost 3,000 children only eight apparent exceptions were found, each of which can be explained by illegitimacy. In addition, to rule out the possibility of illegitimacy, special studies

TABLE 5.—Heredity of the Agglutinogens M and N

Types of Parents	Per Cent of Children of Types		
	MN	M	N
MN × MN	50	25	25
MN × N	50	0	50
MN × M	50	50	0
M × N	100	0	0
M × M	0	100	0
N × N	0	0	100

on mothers and children have been made, and in a series of more than 7,000 such combinations examined up to the year 1935 not a single exception to the second law of heredity was found. Therefore the committee believes that the application of the M-N types in cases of disputed parentage can be recommended without qualification.

The subgroups of groups A and AB have also been found to be hereditary and a plausible theory to explain the method of transmission has been proposed. However, there have been apparent exceptions to

2. When in the reduction division any pair of homologous chromosomes fails to separate, this is known as "nondisjunction."

the theory in the few reports published up to now. Moreover, the technic of determining the subgroups offers certain difficulties. Therefore the committee feels that the application of the subgroups of A and AB in cases of disputed parentage is not established well enough to be used at the present time as a routine procedure.

THE BLOOD TESTS IN THE COURTS

The classic blood group tests have been applied in European countries since 1924 in cases of disputed parentage, and as early as 1929 Schiff was able to compile a series of more than 6,000 cases in which the tests had been used in paternity proceedings (table 6). Incidentally, it is of interest to point out that when

* Am. J. Police Sc. 3:157, 1932 (modified after F. Schiff).

the Bernstein theory is applied in paternity disputes, the chance of excluding an innocent man is approximately one out of six. Since 8.2 per cent of exclusions were obtained on the average (table 6), 8.2×6 , or 49.2 per cent, that is, almost half of the men who denied the charge of parentage, were actually innocent of it.

In countries other than those listed in the table, blood group tests were applied only sporadically until recently. In 1930 the subject received considerable publicity in the United States, when the tests served to solve a hospital case in which two infants were accidentally interchanged before being taken home from a maternity hospital in Chicago. In 1933 the tests came to the fore again in this country, when a falsely accused man was exonerated in Connecticut. In 1934 a similar case occurred in Pennsylvania. In that year impetus was given to the subject in this country by a decision rendered by Justice Meier Steinbrink of the Supreme Court of New York State granting an application for a blood grouping test in a case of disputed paternity. His enlightened decision was reversed, however, by the Appellate Division on the ground that there was no statutory authority for the order. This defect was almost immediately remedied, when laws were enacted in 1935 authorizing courts in New York State to order blood grouping tests in cases of disputed parentage and in civil suits where relevant to issues, and to receive the results in evidence. Shortly thereafter similar laws were enacted in Wisconsin, and there are now bills pending before the legislatures of Montana, California and New Jersey.

It is common knowledge that the tests are of value only to exclude and not to prove parentage. Objection has been raised that if the tests failed to exclude an accused man they might serve unduly to prejudice the judge and more particularly the jury against him. With that in mind, the drafters of the Wisconsin law inserted a provision which prohibits the introduction of the results of the blood tests in evidence except when they exclude the man accused. In 1936 the New York State laws were amended by the inclusion of similar provisions.

It has been impossible to obtain accurate statistics of the number of cases in which blood group tests have been performed for courts here and abroad. All that can be done is to summarize the reports that have appeared in the medical literature. In table 6 is presented a survey of the tests performed up to 1930, and in table 7 is given a summary of the reports that have appeared since the application of the properties M and N has been introduced in paternity proceedings. It will be seen that the chance of excluding paternity has almost been doubled by the M-N tests.

The data given in tables 6 and 7 concerning blood tests in Austria may be supplemented by the following information,

which was forwarded to us by Dr. Josef Franz Holzer in response to a questionnaire sent to him. Dr. Holzer informs us that blood grouping was first introduced in civil and criminal courts of Austria in cases of disputed parentage as early as 1926 in Vienna and Graz, and in 1927 in Innsbruck also. The M-N tests were introduced in Innsbruck in 1932 and in Vienna in November 1933. Since 1930 the blood tests have been used in almost every paternity case at least in Vienna, and there the number of tests performed number many thousands. In Graz during the period 1926-1936 there were 1,250 paternity cases in which the tests for A and B were used, in 418 of which typing for M and N was also performed. In Innsbruck the cases number from forty to fifty every year.

It may be of interest to note that in certain countries the tests are rarely if ever used, no legal provisions having been made for their application. In Italy, for example, paternity research is forbidden except in cases of rape. In a personal communication for Leone Lattes, the most prominent authority on the subject in that country, he states that his experience includes only a few private cases and that he does not know of any case before their courts in which the M-N tests have been used.

In this country the majority of the tests performed for the courts have been done in New York State, as a result of the legislation adopted there. In table 8 is given a list of cases in which blood tests have been made in this country based on the experience of one of the writers (W.) and such reports as could be collected from the literature and by questionnaires. In every case, except the two given below in which the blood tests excluded a certain individual as the parent of a child, the courts accepted the conclusions as final. In one case (reported by Heise), which was tried before a jury, the man was found guilty despite the results of the blood test, because of fancied resemblance between the father of the accused man and the infant. The judge, however, set the verdict aside as being against the weight of evidence and granted a new trial. It is significant that the woman never proceeded with the new trial for the reason that, despite the fact that she and the accused man were both white, the child's features took on definite negroid characteristics as it grew older. In the second case,

* Figures in this column are less than the sum of the two preceding columns since, naturally, there are cases of exclusions made by both methods.

now pending on appeal before the District Court of Appeals of California, the trial court decided against the accused man, 70 years old and impotent, despite the fact that the blood tests exonerated him. On the other hand, several courts in the United States have rendered rather exhaustive and learned opinions favoring the blood tests, of which a few may be cited:

Buschel v. Manowitz 271 N. Y. Supp., 277.
Matter of Swahn 285 N. Y. Supp., 234.
State v. Damm 266 N. W. 667, 104 A. L. R. 430.
State v. Willing 6 Ohio Opinions 371.

In a number of jurisdictions the courts have ordered blood grouping tests even though there was no statute authorizing them to do so. In other jurisdictions the courts require statutory authority to order blood tests or to receive them in evidence, and the lack of proper legislation has hindered a more widespread application of the blood tests.

The committee is of the opinion that such laws should be passed in those states in which they are still required to promote the use of the tests. That such laws should be properly worded and sufficiently explicit is of considerable importance, and hence the following bill now pending before the legislature of California is cited as a model:

An act to add section 1872 to Code of Civil Procedure, relating to blood grouping tests.

The people of the State of California do enact as follows:

SECTION 1. Section 1872 is hereby added to the Code of Civil Procedure to read as follows:

1872. Wherever it shall be relevant to the prosecution or defense of an action, the court, by order, shall direct any party to the action and the child of any such party and the person involved in the controversy to submit to one or more blood grouping tests, the specimens for the purpose to be collected and the tests to be made by duly qualified physicians and under restrictions and directions, as to the court or judge shall seem proper. Whenever such test is ordered and made, the results thereof shall be receivable in evidence only where definite

blood cells alone. In cases in which there is any doubt in the mind of the examiner, the child should be reexamined at a later date when the agglutinins have appeared in the plasma. In general it may be advised that infants should not be examined until they are at least 1 month old.

With regard to the M-N tests, attention should be given to using only the most potent testing fluids, especially for property N, because of the existence of weakly reacting bloods. In general, the testing fluids used should have a minimum titer of 10 to 20. Control blood suspensions of known types M, N and MN must always be included when performing the tests. At least two, preferably three, different testing fluids of each kind should be used.

If the reactions are not clean cut, the tests should be repeated on fresh specimens of blood. If doubt continues to exist, it is essential to state that no definite conclusion can be reached.

Proper identification must be made of the individuals who present themselves for the examinations by their finger prints, signatures or photographs, or by the plaintiff. These precautions are necessary, as is evidenced by the case reported in Europe in which a man sent one of his friends as his substitute; fortunately the attempted fraud was discovered in time.

Although it may seem from the foregoing that the blood grouping tests for determining parentage are complicated and

exclusion shall be established. The order for such blood grouping tests may also direct that the testimony of such experts and of the persons so examined may be taken by deposition.

TECHNIC

The persons who perform blood tests for the courts, if properly qualified, will be fully aware of the pitfalls in the technic and able to avoid them. However, it is deemed advisable to set down certain minimum requirements for the purpose of guiding the expert in rendering his report. The report to the court should consist not only of the statement of the expert's observations and interpretation but also of a brief outline of the method that has been used.

With regard to the four blood group tests, it is important to make an allowance for individual variations in the sensitivity of the red blood cells, particularly in group A and AB, in which there are two or possibly even three sorts of A agglutinogens. The receptor A₂ may be very weak in the new-born, and in subgroup A₂B may be somewhat difficult to detect even in adults. Hence it is important to be certain that the testing serums used are of highest titer. The potency of the serums should be controlled not only when they are put up in vials to be stored but also at the time of the actual test. Furthermore, controls should be made with known blood suspensions of group O and B and subgroups A₁ and A₂ in the tests. As an additional check on the results, the serum of the individuals examined must be tested against blood suspensions of known groups O, A₁, A₂ and B. This is necessary especially in order to detect rare instances of blood A₂Ba₁ which might be taken for blood of group Ba.

Control tests with serum are of little value in infants, but the group can almost invariably be determined by testing the

fraught with difficulty, one should not obtain the impression that with proper organization the method cannot be used safely. This is shown by the experience in European courts, where the method is now firmly established.

QUALIFICATION OF EXPERTS

The qualification of experts may be said to be the most important problem not only as far as blood group tests are concerned but with regard to experts in general. At the present time the expert states his qualifications to the court, which passes judgment on them. But cognizance ought to be taken of the fact that a man who is a preeminent authority in toxicology does not necessarily qualify as a serologist. Since courts may not be in a position to evaluate the special equipment of experts, the committee believes that this entire question should be reviewed and that the authority to qualify medical witnesses should not rest with the court but with some authorized medical body such as the American Medical Association.

It has often been stated, not without some justification, that one can obtain as many experts on one side of the question as on the other. This should be possible only when a question of opinion is involved. When there is a question of fact, as with the results of the blood grouping tests in a case of disputed parentage, there can be only one conclusion rendered by any number of experts in any one case, unless they are not properly qualified and have committed an error in technic, as has actually occurred in Europe (Lauer).

What can happen when untrained persons perform blood group tests for the court was recently demonstrated by two cases in a court in New York City, in which erroneous reports were submitted. In one, the expert stated that the accused man

could not be the father, since he belonged to group O and the child to group A. When the absurdity of his conclusion was pointed out to him, he excused himself by saying that he had "forgotten" to test the mother's blood. In the second case the expert stated that a certain man had been falsely accused, since he belonged to group B, the mother to group O, and the child to group A. Reexamination of the blood specimen by one of us (W.) revealed that the accused man actually belonged to group AB (subgroup A₂B with an atypical α_1 agglutinin).

EXAMINATION OF BLOOD STAINS IN FORENSIC CASES

As the examination of blood stains in forensic cases is a more difficult problem, it will not be gone into in detail in the present report. With very fresh blood, from which suspensions can be prepared, the tests for all groups and types can be done in the usual manner, which makes possible, in all, the differentiation of eighteen distinct classes of human blood. With dried blood stains, a much more difficult technic is required, and the investigator is restricted to the determination only of the four blood groups and the presence or absence of M, since with dried blood the determination of the property N and of the subgroups of A and AB is as yet unreliable. In performing absorption tests on blood stains for the agglutinogens A and B, a point to be stressed is the inclusion of tests of unstained material as a control.

In practice, group determination of old blood stains has proved of only limited value. Putrefied or decomposed blood does not yield reliable results, and even with well preserved stains the material is often insufficient. The qualified investigator, however, will refrain from making any report at all unless the reactions he obtains are absolutely clear and decisive. For the examination of blood stains, particularly, it is essential to have well trained workers, since those not thoroughly familiar with the field seem to have a tendency to offer an opinion in every case although the results may not be conclusive.

To increase the value of group determination in criminal cases, the committee recommends that the proper authorities be advised that all blood stains, whether or not they seem to be of importance, be sent to the laboratory for examination at once, while they are still fresh, and that the results be filed for future reference. Moreover, since the determination of the group rapidly becomes more difficult after death, it is recommended that the determination of the group and M-N type should be made a routine part of the postmortem examination in all cases of violent or unexplained death, whether or not there is suspicion of murder at the time.

With regard to other stains, such as semen and saliva, the same general principles apply, but here the tests are limited to the determination of the four blood groups alone.

RECOMMENDATION

On the basis of the foregoing considerations, the committee recommends that, where necessary, laws should be passed which would authorize courts to order blood grouping tests in cases of disputed paternity, and to receive the results thereof in evidence. Such laws could be modeled after those which have been passed in New York State and Wisconsin and the laws now pending before the legislatures in California and New Jersey. It is also recommended that the question of the qualification of medical experts should be reviewed.

Respectfully submitted.

LUDVIG HEKTOEN, Chairman,
KARL LANDSTEINER.
ALEXANDER S. WIENER.

NEW BUSINESS

Resolutions on the Development of a National Health Program

Dr. Samuel J. Kopetzky, New York, presented the following resolutions, which were referred to the Reference Committee on Executive Session:

WHEREAS, The house of delegates of the Medical Society of the State of New York in annual session at Rochester, 1937, adopted certain resolutions which carried instruction to its delegation to the House of Delegates of the American Medical Association; and

WHEREAS, These resolutions concern the following principles and proposals aimed the development of a national health program and the

special circumstances under which the delivery of a high quality medical care to the American people may be evolved under conditions within the framework of adopted policy of the American Medical Association; and

WHEREAS, These principles and proposals are as follows:

PRINCIPLES

1. That the health of the people is a direct concern of government, and a national public health policy directed toward all groups of the population should be formulated.

(a) In the formulation of such policy the opinions and suggestions of organized medicine should be given preference.

(b) That the House of Delegates of the American Medical Association create a group which shall formulate the principles and proposals of a national health policy to be submitted to the government.

2. That adequate medical care is an essential element of public health and local, state and federal governments need to supplement present efforts of the medical profession to provide it.

(a) That the House of Delegates of the American Medical Association establish a working definition of the term "adequate medical care" suitable for the purpose of discussing national legislation and social legislation.

3. That the problem of economic need and the problem of providing adequate medical care are not identical and may require different approaches for their solution.

(a) Principle 3 implies that the problem of providing the individual with the means of securing medical care—that is, the economic needs—and the problem of distributing medical services are not identical; that these problems of economic needs should be approached separately from those of distributing medical services to the people.

PROPOSALS

1. That the first necessary step toward the realization of the above principles is to minimize the risk of illness by increasing preventive efforts through extension of public health services, federal, state and local.

(a) That the extension of federal, state and local preventive health measures is approved, provided it meets the needs of a given situation in the opinion of the medical profession in the locality affected and provided it integrates to the greatest possible extent the private practitioner of medicine in the development of preventive health services.

2. That the immediate problem is provision of adequate medical care for the medical indigent, the costs to be met from public funds.

3. That public funds should be made available for the support of medical education and for studies, investigations and procedures for maintaining the present high standards of medical practice. This support shall have the majority opinion of organized medicine to recommend it. If this is not provided for, the provision of adequate medical care may prove impossible.

4. That public funds should be available for medical research as essential for high standards of practice in both preventive and curative medicine.

5. That public funds should be made available to hospitals that render service to the medically indigent and for laboratory diagnostic and consultative services.

(a) With the provision that these consultative and laboratory diagnostic services shall be established only in regions where the medical profession approves the need for same and after consultation with the local medical profession in the area affected.

6. That in the allocation of public funds existing private institutions should be utilized to the largest possible extent and receive support as long as their service is in accord with the above proposals.

(a) That insofar as the allocation of funds is concerned for these institutions, they should not be made on a pro rata population basis but should be limited strictly by the needs of given institutions in specified localities and the allocation should have the approval of the medical profession in the locality in which the institutions are located.

(b) That in the selection of existing institutions to which public funds may be allocated their rating and their needs shall be measured by the standards of the Council on Medical Education and Hospitals of the American Medical Association; and that no public funds should be made available to existing institutions against and contrary to the majority opinion of the medical profession in the locality in which they exist.

7. That the investigation and planning of the measures proposed and their ultimate direction should be assigned to experts.

(a) It being recommended that the various subdivisions of the American Medical Association, namely, its national, state and county components, furnish to the government on request lists of experts in their communities to carry out these principles and proposals.

(b) That the word "expert" is taken to mean a man especially qualified by experience in his specific field. Nominations of these "experts" should be by units of organized medicine. The nominations and recommendations by organized medicine should be given preferential consideration by government in making its selection.

8. That the adequate administration and supervision of the health functions of the government, as implied in the above proposals necessitates, in our opinion, a functional consolidation of all federal health and medical activities under a separate department.

9. That we who subscribe to the above principles, proposals and recommendations hold the view that compulsory health insurance does not offer a satisfactory solution on the basis of these principles and proposals and repeat our objections to its enactment in this country; therefore be it

Resolved, That the House of Delegates of the American Medical Association endorses the principles, proposals and recommendations just cited; and be it further

Resolved, That the House of Delegates authorize the formation of a committee which shall, in conformity to the above, formulate a national health policy for submission to the government, and further be empowered to confer with government agencies and also with any other medical groups so that differences in conception, definition of terms and applicability of principles and procedures may be ironed out in conference regarding those matters in the above principles and proposals which are of national scope and to the end that they may be enacted.

Resolution on Socialization of Medicine

Dr. Harold T. Low, Colorado, announced the introduction of a resolution dealing with socialization of medicine, which was referred to the Reference Committee on Executive Session.

Resolutions on the Family Physician and the School Child

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The family physician has labored for these many years without full recognition of his valuable services; and

WHEREAS, The various school systems of the United States depend on the family doctor for the prevention and diagnosis of disease and the protection of the public; therefore be it

Resolved, That the school boards and authorities in charge of the school systems all over our country be respectfully requested to enter and file on the index card of every school child the name and address of the chosen family doctor; and be it further

Resolved, That the designated family doctor, together with the parents or guardians of the child, be informed by the proper school authorities of any accident or illness that may befall the child in the schools of this country.

Resolution Requiring Physicians on Staffs of Accredited Hospitals to Be Members of the American Medical Association

Dr. John Z. Brown Sr., Utah, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, It has been forcibly brought to our attention that some of the celebrated hospitals of the country have on their staffs doctors of medicine who are not members of their county medical societies; and

WHEREAS, This fact is not healthful to organized medicine and is detrimental to the doctor's reputation among his colleagues, and further that such nonaffiliation may interfere with a physician's application for license by reciprocity in another state; therefore be it

Resolved, That the Utah State Medical Association disapproves such condition and, through its house of delegates, requests the House of Delegates of the American Medical Association to take similar action and urge the Council on Medical Education and Hospitals to add to its requirements for approval that doctors on the staffs of accredited hospitals should be members of the American Medical Association.

Resolutions Recommending Establishment of Council on Medical Ethics and Economics

Dr. Carl F. Vohs, Missouri, presented the following resolutions from the Missouri State Medical Association, which were referred to the Board of Trustees:

WHEREAS, There are unmistakable indications that compulsory health insurance and other phases of state medicine are among the plans of our federal government; and

WHEREAS, The public and some members of the medical profession have not sufficient knowledge of the consequences of such services; and

WHEREAS, Adequate scientific medical treatment of the sick and afflicted is our first consideration; and

WHEREAS, Such projects involve the appointment of physicians and surgeons, which should be done in accordance with the recommendations of the American Medical Association; and

WHEREAS, The state association and ultimate county unit societies have demonstrated their inability properly to discipline their members; therefore be it

Resolved, That the American Medical Association shall establish a Council on Medical Ethics and Economics for a thorough study of the entire situation and everything which it might entail and give widespread publicity to all the phases of its activities; and be it further

Resolved, That the By-Laws and regulations of the American Medical Association be so amended that this Council on Medical Ethics and Economics may also investigate alleged unethical conduct which may be brought to its attention and prosecute the apparent violations before the Judicial Council of the Association for ultimate disposition as to innocence or guilt, with either exonerations or punishment; and be it also

Resolved, That our delegates be instructed to present this action to the House of Delegates of the American Medical Association at the Atlantic City session in June 1937.

Resolutions Requesting Change of Name of Section on Obstetrics, Gynecology and Abdominal Surgery

Dr. George Gray Ward, Section on Obstetrics, Gynecology and Abdominal Surgery, presented the following resolutions, which were referred to the Reference Committee on Sections and Section Work:

WHEREAS, The Council on Medical Education and Hospitals has recently recognized Obstetrics and Gynecology as a specialty; and

WHEREAS, The Scientific Assembly provides adequately for the discussion of problems of abdominal surgery within the Section on Surgery, General and Abdominal; therefore be it

Resolved, That the Section on Obstetrics, Gynecology and Abdominal Surgery request the House of Delegates to change the name of the section to the Section on Obstetrics and Gynecology; and be it further

Resolved, That the Section on Obstetrics, Gynecology and Abdominal Surgery instruct its delegate to present this resolution to the House of Delegates at its regular meeting in 1937.

Resolution on Review of Motion Picture Films

Dr. Thomas P. Farmer, New York, presented the following resolution, which was referred to the Board of Trustees:

WHEREAS, Motion picture films are being publicly offered gratis or on a rental basis, by organizations, commercial and noncommercial, for inclusion in programs of county medical societies, accompanied in some instances by speakers; and

WHEREAS, Some of these films carry advertising matter or objectionable propaganda; and

WHEREAS, These matters have been brought to the house of delegates of the Medical Society of the State of New York and there approved and the New York delegation instructed to present the following; therefore be it

Resolved, That the House of Delegates of the American Medical Association make provision through some suitable bureau or department of its central office to review these films, classify them and through THE JOURNAL publish information anent them to the end that members and officials of component organized units of the American Medical Association be fully informed regarding such films and have some measure of guidance in selecting them for inclusion on their local programs.

Resolution on Production of Educational Films

Dr. C. A. Dukes, California, presented the following resolution, which was referred to the Board of Trustees:

WHEREAS, The public today is seeking and demanding dependable health information and knowledge; and

WHEREAS, This demand is being partly met by self-seeking, non-authentic and nonscientific sources, namely, the advertisers and venders of remedies, and self-constituted, inadequately educated cults and charlatans; and

WHEREAS, Misleading and false information is being transmitted to the public through the various avenues of publicity which constitute a very definite menace to the health welfare of the public of this nation, and, therefore, demands the concerted action of organized medicine to aid and support the physician in fulfilling his duty to the public as expressed in sections 1 and 3, Chapter IV of the Principles of Medical Ethics of the American Medical Association; and

WHEREAS, Methods and channels through which educational information is being imparted have materially changed in the past twenty-five years from the written page to the radio, and now to the motion pictures with sound effect; and

WHEREAS, Motion pictures bringing the story of medicine to the public have been used in a very limited way by the profession and by organized medicine; and

WHEREAS, The visual story of medicine in film lends itself to dramatization of great general interest and offers effective means for desirable educational work in the public's behalf, and will create an appreciation of science of medicine and of those who represent it; and

WHEREAS, Motion picture films must be of understandable, pictorial and dramatic quality that calls for the expenditure of money for scenarial writing of scripts and dialogue; and

WHEREAS, Such monies cannot be expended by individual physicians or by component medical units; and

WHEREAS, Motion picture films of a character contemplated in this resolution should be used nationally to the benefit of the public; therefore be it

Resolved, That this House of Delegates requests the Board of Trustees to give serious and immediate consideration to the production of educational films, with and without sound track, and that such films be made available for the various component state and county medical societies throughout the country for these educational purposes.

Resolution on Importance of Preventive Medicine

Dr. Terry M. Townsend, New York, presented the following resolution from the Medical Society of the State of New York, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The Medical Society of the State of New York in annual meeting assembled at Rochester, 1937, adopted recommendations made by its president and also resolutions originating in the Medical Society of the County of New York that during the ensuing year preventive

medicine be stressed by giving it a place on county and district branch programs and by featuring it in the *New York State Journal of Medicine* and also in addresses before lay groups wherever possible; and

WHEREAS, These recommendations were endorsed and approved by the house of delegates of the Medical Society of the State of New York and their presentation to the House of Delegates of the American Medical Association directed; therefore be it

Resolved, That the American Medical Association reiterates its stand on the importance of preventive medicine and urges on all component bodies that every effort be made to promote all features of preventive medicine, to make the same available to the public and so to feature the achievements of preventive medicine as to create a larger demand for it by the public.

Resolution on Program of Public Education

Dr. Fred Moore, Iowa, presented the following resolution from the Iowa State Medical Society, which was referred to the Board of Trustees:

WHEREAS, There is and will be continued interest on the part of the public in medical news and in various plans for provision for medical services to groups of people; and

WHEREAS, Much of the publicity of the past conveys little truth in the field of discovery and much that is misleading in the field of economics; and

WHEREAS, Much of the reaction and the attitude of the medical profession to said publicity is misunderstood by the public; and

WHEREAS, Education by publicity requires special experience and technics largely foreign to our profession; and

WHEREAS, The medical profession of this nation needs more adequate publicity and guidance in these respects; therefore be it

Resolved, By the House of Delegates of the American Medical Association that the Board of Trustees should employ additional and competent personnel to develop on a national scale a program of public education that will be designed to foster better understanding by the laity in the field of medical science and particularly better understanding by the public of its interests and the interests of the medical profession in the various sociologic and economic schemes and plans which involve provision of medical services.

Resolutions to Be Brought Up in Executive Session

Dr. W. Albert Cook, Oklahoma, submitted resolutions to be brought up in Executive Session, which were referred to the Reference Committee on Executive Session.

Resolutions from Medical Society of New Jersey

Dr. Walt P. Conaway, New Jersey, presented the following resolutions:

At the regular annual meeting of the house of delegates of the Medical Society of New Jersey on Wednesday afternoon, April 28, 1937, the following resolutions were introduced at the direction of the welfare committee and passed by the house:

RESOLUTION ON INVESTIGATION INTO CONDUCT OF MAGAZINE "HYGEIA"

The following resolution was referred to the Board of Trustees:

Resolved, That our delegates to the American Medical Association be instructed to introduce a resolution into the House of Delegates of the American Medical Association calling for an investigation into the conduct of the magazine *Hygeia*, particularly as to articles that prescribe for the laity, and into the methods employed by the business manager in circularizing the laity with literature designed at least to imply that *Hygeia* magazine will take the place of a medical adviser.

RESOLUTION ON OPPOSITION TO COPELAND FOOD AND DRUG BILL

The following resolution was referred to the Reference Committee on Legislation and Public Relations:

Resolved, That the Medical Society of New Jersey reaffirms the actions of this body of the past three years in opposition to the permissive and pernicious provisions of the Copeland Food and Drug Bill, and instructs its delegates to the approaching session of the American Medical Association to bend their efforts to develop a constructive program in the American Medical Association toward preservation of the Mandatory provisions and the distribution of responsibility of the Food and Drugs Law of 1906.

Resolutions on Clarifying Policy of the American Medical Association on Question of Group Hospitalization

Dr. C. W. Stone, Ohio, presented the following resolutions adopted by the house of delegates of the Ohio State Medical Association on April 29, 1937, which were referred to the Reference Committee on Medical Education:

WHEREAS, An increasing interest in group hospital payment plans has been demonstrated in recent months in several metropolitan centers of Ohio; and

WHEREAS, There are definite problems of direct interest to the medical profession involved in such projects; and

WHEREAS, The present policy of the Ohio State Medical Association, as established by official action of the council on Oct. 29, 1933, declares that medical service should not be included among services furnished under group hospitalization contracts; and

WHEREAS, Confusion and controversy exist with respect to a differentiation between medical services and hospital services in many group hospitalization programs; be it

Resolved, That the house of delegates of the Ohio State Medical Association this 29th day of April 1937, reaffirms the policy adopted by the council of this association on Oct. 29, 1933; and be it further

Resolved, That the house of delegates of this association respectfully requests the officials and House of Delegates of the American Medical Association to consider, at the forthcoming session of the American Medical Association at Atlantic City, the advisability of clarifying its policy on the question of group hospitalization, especially on the matter of defining and enumerating the services which should not be included because they are definitely medical services.

Resolutions on Presentation of Exhibit of the American Medical Association at San Francisco International Exposition

Dr. Elbridge J. Best, California, presented the following resolutions, which were referred to the Board of Trustees:

WHEREAS, The San Francisco International Exposition will be opened in February of 1939; and

WHEREAS, A special building will be constructed for education and science; and

WHEREAS, The Exposition management has requested the California Medical Association to appoint an advisory committee and to exercise censorship over all exhibits relating to medicine and public health; therefore be it

Resolved, That the Board of Trustees be requested to prepare a suitable exhibit representative of the American Medical Association; and be it

Resolved, That the Board of Trustees direct the Association's Director of Exhibits to cooperate with the advisory committee of the California Medical Association.

Proposed Amendments to the Principles of Medical Ethics

Dr. George Edward Follansbee, Chairman, Judicial Council, presented the following proposed amendments to the Principles of Medical Ethics, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Amend section 2 of article 6 of chapter III of the Principles of Medical Ethics so that only the first paragraph shall be included in that section under the heading "Conditions of Medical Practice," and that the remaining three paragraphs of that section shall be included under a section 3 with the heading "Contract Practice."

Amend the first paragraph of the new section 3 to read as follows:

SEC. 3.—By the term "contract practice" as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization or individual, to furnish partial or full medical services to a group or class of individuals on the basis of a fee schedule, or for a salary or a fixed rate per capita.

In accordance with the above proposed amendments, the present section 3, article VI, under the heading "Commissions," becomes section 4, and the present section 4 under the heading "Direct Profit to Lay Groups," becomes section 5.

Proposed Amendments to the By-Laws

Dr. George Edward Follansbee, Chairman, Judicial Council, presented the following proposed amendments to the By-Laws, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws:

PROPOSED AMENDMENT TO CHAPTER XI, SECTION 1

WHEREAS, It is undesirable to carry on the membership roll and in the directory of physicians the names of members convicted of felonies; be it

Resolved, That the By-Laws, chapter XI, section 1, be amended by adding after the first sentence: "Conviction of a felony shall automatically remove a member's name from the membership roll for a period of not less than one year after the termination of punishment for the offense."

PROPOSED AMENDMENT TO CHAPTER IX, SECTION 1

Amend chapter IX, section 1, of the By-Laws by adding to the second paragraph the following sentence: "The period of time within which appeal to the Judicial Council may be taken shall be limited to the six months following the date of decision by the constituted authority of a constituent association."

PROPOSED AMENDMENTS TO CHAPTER IV, SECTIONS 1 AND 8

Amend chapter IV, section 1, last sentence to read "No member of the House of Delegates nor general officer of the Association shall be eligible for election to the office of President-Elect or Vice President."

Amend chapter IV, section 8, to read, "INSTALLATION AS PRESIDENT.—The President-Elect shall be installed as and assume the duties of President at the opening general meeting of the Scientific Assembly of the annual session following that at which he was elected."

Proposed Amendment to the Constitution

Dr. George Edward Follansbee, Chairman, Judicial Council, presented the following resolution proposing an amendment to the Constitution, article 6, section 2, which the Speaker declared may be acted on at the next annual session:

WHEREAS, The Constitution and the By-Laws refer to the election annually of a president and president-elect when in fact only a president-elect is elected; and

WHEREAS, No provision is made in the Constitution and By-Laws for a succession in office in case of death or disability of the President-Elect; be it

Resolved, That article 6, section 2, of the Constitution be amended to read, "(a) The President-Elect shall be elected annually. He shall serve as President-Elect until the annual session of the Association next ensuing after his election and shall become President on his installation in the course of that session, serving thereafter as President until the next following annual session and the installation of his successor. If the President-Elect dies, resigns, or in the judgment of the Board of Trustees confirmed by the House of Delegates is permanently disqualified for the performance of the duties of his office by any just cause, the Vice President shall become President-Elect and in due course succeed to the presidency, with all of the prerogatives and duties pertaining to that office, as fully as if elected to it in the first instance: Provided, however, that the President-Elect who is elected at the annual session of the Association in 1937 shall, notwithstanding his election as such for the period of one year only, be installed as President in the course of the session in 1938 and continue as such until the session in 1939 and the installation of his successor.

(b) A Vice President, a Secretary, a Treasurer, and a Speaker and a Vice Speaker of the House of Delegates shall be elected, each to serve for one year and until his successor is elected and installed: Provided, however, that in event of the death, resignation or removal, or of the permanent disability of the President-Elect as determined by the Board of Trustees, the Vice President shall succeed to the office of President-Elect and in due course to the office of President, notwithstanding the fact that he was in the first instance elected as Vice President for one year only."

Resolution Requesting the North Central Association of Colleges to Amend Its Manual

Dr. T. R. K. Gruber, Michigan, on behalf of the Michigan State Medical Society, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, It appears from perusal of the manual of the North Central Association of Colleges and Secondary Schools, which manual sets forth the requirements for approval under section 48 of the manual, Health Service; and

WHEREAS, The requirements mentioned above are broad and far reaching, and, in fact, set up for the use of the student body what is closely akin to state medicine; and

WHEREAS, The student body being in their formative years are being taught to utilize this type of service; and

WHEREAS, This service destroys the patient-physician relationship; and

WHEREAS, The principles set forth are already in variance with the ideas of the proper practice of medicine as set forth by the American Medical Association; be it therefore

Resolved, That the North Central Association of Colleges and Secondary Schools be requested to delete this requirement from their manual and allow each school to set up an individual service for the school, said service to be planned and executed in conjunction and with the approval of the local county medical society.

Resolution on Establishment of a Department of Public Relations

Dr. L. J. Hirschman, Michigan, in behalf of the Michigan State Medical Society, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The Congress of the United States and many state legislatures throughout the country are being prevailed on to enact systems of compulsory health insurance; and

WHEREAS, The general public is not fully aware of the deleterious effects such experiments would have on the quality of medical care, nor of the resulting economic burdens; and

WHEREAS, It is of vital concern to all persons that a complete and correct picture of the situation be immediately and universally publicized; therefore be it

Resolved, That the Michigan State Medical Society recommends that the American Medical Association consider the establishment of a Department of Public Relations whose function it shall be to engage the most expert and talented professional public relations counsel available, this Department of Public Relations to be equipped with adequate financial resources to carry on a permanent campaign of publicity and educational announcements through the most effective mediums to reach the masses of public opinion and set forth dramatically and accurately the story of medical progress and service in the United States.

Resolution on Administration of Anesthesia

Dr. Walter A. Lane, Massachusetts, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Resolved, That the employment of nurses, technicians and lay individuals, excepting those registered in the active pursuit of a medical degree, as anesthetists or for the parenteral administration of drugs or serums is an encroachment on the field of medical practice, is basically illegal, unethical and should not be tolerated in the best interests of the patient.

Amendments to Constitution and By-Laws

Dr. George Edward Follansbee, Chairman, Judicial Council, resubmitted proposed amendments to the Constitution and By-Laws, approved but not adopted by the House of Delegates at the Kansas City session in 1936, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws.

The meeting recessed at 1:50 p. m. to reconvene Tuesday morning, June 8, at 9:30.

(To be continued)

REGISTRATION AT ATLANTIC CITY

The total registration at the Atlantic City session was 9,764. Below are given two summaries—one by sections and one by states:

Registration by Sections

Practice of Medicine.....	3,156
Surgery, General and Abdominal.....	1,325
Obstetrics, Gynecology and Abdominal Surgery.....	666
Ophthalmology	475
Laryngology, Otology and Rhinology.....	414
Pediatrics	536
Pharmacology and Therapeutics.....	52
Pathology and Physiology.....	275

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Changes in the Faculty at Yale.—Dr. Leonard Greenburg, New York, executive director of the department of industrial hygiene, New York State Department of Labor, and associate clinical professor of public health, Yale University School of Medicine, New Haven, has been promoted to professor of public health. Other promotions include:

Dr. Daniel C. Darrow, associate professor of pediatrics.
Dr. Edwin F. Gildea, associate professor of psychiatry.
Dr. Howard S. Colwell, associate professor of medicine.
Dr. Hugh M. Wilson, associate professor of radiology.
Dr. Ralph H. Jenkins, associate professor of urology.
Dr. John H. Bumstead, assistant professor of medicine.
Dr. Harry E. Klebanoff, assistant professor of medicine.
Dr. Bernhard A. Rogowski, assistant professor of neurology.
Dr. Louis S. Goodman, assistant professor of pharmacology and toxicology.
Dr. Paul H. Lavietes, assistant professor of medicine.
Ralph G. Meader, Ph.D., assistant professor of anatomy.
Dr. Herman Yarnet, assistant professor of pediatrics.

DISTRICT OF COLUMBIA

New Prize Awarded to Dr. Dowling.—The Washington Medical and Surgical Society awarded its newly established merit prize in medicine, May 22, to Dr. Harry F. Dowling, director of laboratories, George Washington University Hospital, for research on pneumonia, it is reported. The prize was established in honor of Dr. Frank E. Gibson, permanent treasurer of the society, and will be presented each year to "an outstanding figure in medicine in the city." Dr. Dowling is 32 years of age and a graduate of the George Washington University School of Medicine, class of 1931. Dr. Gibson also graduated from George Washington. He is 64 years of age. The award was presented to Dr. Dowling by Dr. Tomas Cajigas, formerly president of the society.

Society News.—At a meeting of the section on ophthalmology and otolaryngology of the Medical Society of the District of Columbia, April 16, the speakers were Drs. Eldridge S. Adams on "Present Status of Aviation Medicine in China"; Mervin C. Myerson, New York, "Petrositis," and Earle G. Breeding and Herbert H. Schoenfeld, "Report of Case of Petrositis with Recovery." In the afternoon, Dr. Myerson gave cadaver demonstrations of various operations for petrositis at Georgetown University School of Medicine. A symposium on cataract was presented before the Washington Ophthalmological Society, May 31, by Drs. Clyde A. Clapp, Baltimore; Edmund B. Spaeth, Philadelphia; Conrad Berens, New York; Robert Von der Heydt, Chicago, and Lieut. Col. James E. Ash, of the Army Medical Museum.

GEORGIA

University News.—Dr. George W. McCoy, medical director, U. S. Public Health Service, Washington, D. C., addressed the Dugas Journal Club of the University of Georgia School of Medicine, May 17, on "Relationship of Epidemiology to Public Health."

Health Department Activities.—A silver goblet was presented to Dr. Hugo Robinson, who recently retired as health commissioner of Dougherty County, at a meeting of the board of health in Albany, May 6. He had held the office since 1920. The new health officer is Dr. Thomas W. Collier, College Park. Dr. William C. Humphries has resigned as health officer of the city of Griffin and Spalding County and will return to his home in Acworth, it is reported.

ILLINOIS

Hospital News.—The new wing of the Moline Public Hospital was dedicated recently. The Rock Island County Medical Society held its meeting in the new building May 11, and Dr. Frederick M. F. Meixner, Peoria, spoke on "Treatment of Pneumonia."

Memorial Services for Dr. Gahagan.—An oil portrait of the late Dr. Henry J. Gahagan was presented to the Mercyville Sanatorium, Aurora, during memorial services in his honor May 2. Dr. Gahagan was director of the sanatorium from 1917 until his accidental death Nov. 9, 1936.

Chicago

Campaign Against Illegal Practitioners.—The Illinois State Department of Registration, in its current campaign against illegal practitioners, reports the following disposition of cases:

Louis Marinakos, 1209 South Cicero Avenue, Cicero, Ill., pleaded guilty, May 14, and was fined \$100 and costs.
M. Koltunski, 1032 North Ashland Avenue, found guilty, May 19, and fined \$100 and costs and placed on six months probation.
F. W. Ackerman, 4026 North Kimball Avenue and 4009 Bernard Street, acquitted by a jury May 17.
Otto C. Mollnhauer, 3440 West Fullerton Avenue, found guilty, June 2, and fined \$100 and costs and placed on one year's probation.
J. E. Bradley, Aero Laboratories, 1549 North Western Avenue, found guilty, May 24, and sentenced to thirty days in the county jail.

IOWA

Society News.—At a meeting of the Des Moines Academy of Medicine and the Polk County Medical Society in Des Moines, recently, Dr. Lewis M. Overton spoke on "Chronic Low Back Pain from the Orthopedic Viewpoint" and Dr. Charles Harlan Johnston, "Combined Ligation and Injection Treatment of the Varicose Great Saphenous Vein." Drs. Harold C. Black and Lester D. Powell addressed the meeting, May 25, on arthritis and regional ileitis, respectively. Dr. Harris P. Mosher, Boston, will discuss "Modern Views of the Esophagus" before the Linn County Medical Society, June 29, in Cedar Rapids.

Public Health Meeting.—The Iowa Public Health Association held its eleventh annual meeting in Des Moines, May 20-21. The speakers included Drs. Walter L. Biering, Des Moines, state health commissioner, "Extension of Health Services Through State, Local and Federal Resources"; Everett D. Plass, Iowa City, "Syphilis in Relation to Pregnancy," and Philip C. Jeans, Iowa City, "Management of Congenital Syphilis." A symposium on convalescent serum was presented by Drs. Carl F. Jordan, Paul Stephen and Lee F. Hill, all of Des Moines, and Jack V. Treynor, Council Bluffs. Dr. William Woodburn, health officer of Boone, was chosen president of the society.

LOUISIANA

State Pediatric Meeting.—Dr. Clarence H. Webb, Shreveport, was elected president of the Louisiana State Pediatric Society at its annual meeting in Monroe, April 26. Dr. Ralph J. Talbot, Monroe, was elected vice president and Dr. Ruth G. Aleman, New Orleans, reelected secretary-treasurer. At the banquet Dr. Edwin A. Socola, New Orleans, retiring president, gave an address on "The Peril of School Children from Moral Degenerates"; other speakers were Drs. Charles J. Bloom, New Orleans, on "Evaluation of Teeth in Their Relation to Pediatrics" and Stanley George Wolfe, Shreveport, "Vaccination Against Smallpox with Rivers' Cultured Virus."

New Professors in the Graduate School of Medicine.—Dr. Valentine H. Fuchs, New Orleans, has been appointed professor of otorhinolaryngology and director of the department in the Graduate School of Medicine of the Louisiana State University Medical Center, according to the Orleans Parish Medical Society Bulletin. The appointment of Dr. Henry W. E. Walther, New Orleans, as professor and head of the department of urology was also announced. Dr. Fuchs is 42 years of age. He graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1917. Dr. Walther, who is 49 years of age, graduated from the same school in 1910.

MARYLAND

University News.—Dr. Madge Thurlow Macklin, professor of histology and embryology, University of Western Ontario Medical School, London, gave the Catherine Milligan McLane Lecture at Goucher College, Baltimore, April 15; her subject was "The Inheritance of Disease and Its Relation to the Practice of Medicine."

Portrait of Dr. Winslow.—A portrait of the late Dr. Randolph Winslow, Baltimore, was presented by the Winslow family to the Medical and Chirurgical Faculty of Maryland during its recent annual meeting in Baltimore. Dr. Thomas S. Cullen made the presentation on behalf of the family. Dr. Winslow was president of the faculty in 1914. He served as a member of the House of Delegates of the American Medical Association in 1905-1906, 1911, 1913, 1916-1923, 1927-1934, and of the Judicial Council from 1915 to 1922. He was a founder of the American College of Surgeons and served at one time as president of the Baltimore City Medical Society and the Southern Surgical Association. He graduated from the University of Maryland School of Medicine and was for many years a mem-

ber of its faculty, where at the time of his death, February 27, he was emeritus professor of surgery. He once taught at the Woman's Medical College, Baltimore.

MASSACHUSETTS

Dr. Anderson Goes to University of Minnesota.—Dr. Gaylord W. Anderson, director of the division of communicable diseases, Boston, has been appointed professor and head of the department of preventive medicine and public health of the University of Minnesota School of Medicine, Minneapolis. He succeeds Dr. Kenneth F. Maxcy, who resigned to become professor of bacteriology at Johns Hopkins University School of Medicine, Baltimore. Dr. Anderson graduated from Harvard University Medical School in 1928.

MICHIGAN

Society News.—The Jackson County Medical Society was addressed in Jackson, May 18, by Dr. Raymond W. Waggoner, Ann Arbor, on epilepsy. At a meeting of the Ingham County Medical Society, Lansing, May 18, Dr. Louis M. Warfield, Milwaukee, spoke on "Nature and Treatment of Peripheral Circulatory Collapse." Dr. Frederick G. Novy, Ann Arbor, addressed the Wayne County Medical Society, Detroit, May 17, on "Fifty Years in Retrospect." He was presented with a certificate of honorary membership during the meeting. Dr. Clifford H. Keene discussed "Experiences with Prontosil and Prontylin at the University Hospital, Ann Arbor" before the Oakland County Medical Society, June 2.

Principal Causes of Death.—Ten major causes of deaths accounted for 70 per cent of the 54,777 deaths recorded in Michigan in 1936, it is reported. Heart disease led the list with a total of 10,010 deaths, an increase over the 9,606 deaths reported in 1935. Cancer occupied second place with a total of 5,543 deaths in 1936 as compared with 5,191 in 1935. Deaths by violence moved into third place, the report stated, 5,246 deaths being attributed to this cause. This total includes 1,009 deaths ascribed to heat prostration and 1,913 deaths to automobile accidents. Other leading causes of death, as they appear in the state department of health's report, are as follows: Cerebral hemorrhage, with a total of 4,175 deaths, the only major cause of death to show a decrease from 1935 figures; pneumonia, 4,096 as compared with 3,802 in 1935; nephritis, 3,038; angina and coronary disease, 2,888; tuberculosis, 2,102 deaths, an increase of fifty-eight over 1935; premature birth, 1,395, and diabetes, 1,266.

MINNESOTA

Warning Against Unlawfully Prescribing Liquor.—The Liquor Control Commissioner of Minnesota called the attention of the Minnesota State Board of Medical Examiners to violations of the state liquor control act by physicians, particularly in the twenty-eight dry counties of the state. An investigation, conducted jointly by the commissioner and the medical board, disclosed a practice among certain physicians and druggists whereby the physicians issued, with or without remuneration, hundreds of prescriptions to be used at the convenience of druggists in the sale of alcoholic liquor. Some of the prescriptions were written in blank and merely signed by the physician. Others, although calling for whisky, failed to specify the name of the person for whom they were intended. February 6, as a result of the investigation, four Minnesota physicians were reprimanded by the medical board after a hearing before that body. The medical board has issued a warning to the medical profession of Minnesota that further violations of the state liquor control act by physicians will result in prosecution and disciplinary action by the board.

MISSOURI

New Dean at Washington.—Philip A. Shaffer, Ph.D., professor of biologic chemistry and head of the department, Washington University School of Medicine, St. Louis, has been appointed dean succeeding the late Dr. W. McKim Marriott, who had resigned to take over a similar position at the University of California Medical School, San Francisco. Dr. Shaffer had been a member of the administrative committee which had been appointed following Dr. Marriott's resignation pending the selection of a new dean. Dr. Shaffer received his degree of doctor of philosophy at Harvard in 1904 and in the same year joined the faculty at Cornell University Medical College. In 1910 he became professor of biologic chemistry and head of the department at Washington and from 1915 to 1919 served as dean of the school.

Dr. Dean Receives Gold Medal.—Dr. Lee Wallace Dean, professor of otolaryngology, Washington University School of Medicine, St. Louis, was presented with the gold medal of the American Laryngological Association at its annual meeting in Atlantic City, June 1. The medal was established by the wife of the late Dr. Arthur W. De Roaldes, New Orleans, to serve as a memorial to him and is presented from time to time through the association. Dr. Dean, a former president of the association, is the fourth recipient to receive the award in about twenty-five years, it was stated. Others were Drs. D. Bryson Delavan, New York, Chevalier Jackson, Philadelphia, and Harris P. Mosher, Boston. Dr. Dean graduated from the State University of Iowa College of Medicine in 1896. He served for many years at his alma mater as professor and head of the department of otolaryngology and oral surgery and as dean of the college of medicine. In 1927 he resigned from the faculty to become associated with Washington University. He is 64 years of age.

MONTANA

Pacific Northwest Medical Meeting.—The sixteenth annual session of the Pacific Northwest Medical Association will be held at Great Falls, July 15-17, with the following guest speakers:

Dr. Anton J. Carlson, professor of physiology, University of Chicago.
Dr. Frederick C. Rodda, associate professor of pediatrics, University of Minnesota Medical School, Minneapolis, and the graduate school.
Dr. ... professor of clinical investigation in internal medicine, Medical School, Ann Arbor.
Dr. ... University of ...
Dr. ... University of Minnesota, Grad ...
Dr. Norman F. Miller, professor of obstetrics and gynecology, University of Michigan Medical School, Ann Arbor.

Further information may be obtained from the secretary, Dr. Clyde W. Countryman, 262 Paulsen Medical and Dental Building, Spokane, Wash.

NEW YORK

Personal.—Dr. Arthur W. Johnson, Mechanicville, was guest of honor at a testimonial dinner, April 7, given by the Saratoga County Medical Society to celebrate his completion of twenty years as coroner of the county. Speakers included Drs. William Van Doren, Mechanicville, who presided, and Walter S. McClellan, Saratoga Springs, and Edwin MacDonald Stanton, Schenectady.

Society News.—Dr. John E. Jennings, Brooklyn, addressed the Medical Society of the County of Nassau, April 27, on "Surgical Complications of Influenza." Dr. Elliott P. Joslin, Boston, addressed the Broome County Medical Society, Binghamton, April 14, on "The Treatment of Diabetes and Especially the Use of Protamine Insulin." Dr. Donald Guthrie, Sayre, Pa., discussed "Diagnosis and Treatment of Malignant Diseases of the Breast" before the Medical Society of the County of Cortland, April 16.

New York City

Personal.—Dr. Herbert S. Gasser, director of the Rockefeller Institute for Medical Research, has been elected a trustee of the Rockefeller Foundation. Dr. Willis G. Nealley was presented with a gold watch in appreciation of his twenty-five years service as medical director of Brooklyn Hospital. Dr. Joseph Jordan Eller has been made an honorary member of the Argentine Society of Dermatology.

Society News.—A symposium on pituitary basophilism was presented before the New York Endocrinological Society, May 26, by Drs. Bernard S. Oppenheimer, Solomon Silver, Irving H. Pardee and Aaron S. Blumgarten. The Medical Society of the County of Queens held a joint meeting with the Queens County Bar Association, April 27, with the following speakers: Justice Meier Steinbrink of the state supreme court on "Medical Jurisprudence as It Affects the Medical Profession"; Dr. Manel E. Marten, "Science in Crime Detection," and Max D. Steuer, New York attorney, "The Supreme Court and the President." Dr. Raphael Kurzrok discussed "Recent Advances in the Physiology of Sex and Reproduction" before the Bronx Gynecological and Obstetrical Society, May 17.

University News.—Dr. C. U. Ariens Kappers, professor of comparative neurology at the University of Amsterdam, gave an address at Long Island College of Medicine, April 7, on "The Autonomic Center of the Hypothalamus." Dr. Charles G. Kerley, emeritus professor of pediatrics, New York Polyclinic Medical School and Hospital, gave a lecture at the school, April 14, on "Making Milk Safe for Babies." A department of nursing has been established at Columbia University with full university rating and under

the direction of the faculty of medicine. Nursing education has hitherto been administered by the school of nursing of Presbyterian Hospital, with the instruction in medical and surgical subjects. Graduates will receive the degree of bachelor of science.

NORTH CAROLINA

State Medical Election.—Dr. James B. Sidbury, Wilmington, was chosen president-elect of the Medical Society of the State of North Carolina at its annual meeting in Winston-Salem, May 5, and Dr. Wingate M. Johnson, Winston-Salem, was inducted into the presidency. Dr. Thomas W. M. Long, Roanoke Rapids, is the new secretary to succeed Dr. Louis B. McBrayer, Southern Pines, who retired after many years' service. The next annual session will be held in Pinchurst, May 2-4, 1938.

Dr. Mangum Resigns as Dean.—Dr. Charles S. Mangum, dean of the University of North Carolina Medical School, Chapel Hill, has asked to be relieved of his duties, according to newspaper reports, May 28. He has held the position since 1933. Dr. Mangum, who is 66 years of age, graduated from Jefferson Medical College in 1894. Two years later he joined the faculty at North Carolina as professor of physiology and materia medica. From 1900 to 1905 he served as professor of pharmacology and demonstrator of anatomy, and since 1905 as professor of anatomy.

OHIO

Outbreak of Spinal Meningitis.—Four deaths in four days were reported in an outbreak of spinal meningitis in Kent, according to the newspapers, May 19. The first death occurred in a youth 20 years of age, a student at the Kent State College, who became ill while working in a restaurant. The other victims were a 5 months old girl, a boy of 12 and a youth of 19, who died after becoming ill in the county jail.

OKLAHOMA

State Medical Election.—Dr. Henry K. Speed, Sayre, was named president-elect of the Oklahoma State Medical Association at its annual meeting in Tulsa, May 11, and Dr. Samuel A. McKeel, Ada, was installed as president. The next annual meeting will be held in Muskogee.

New Superintendents of Health.—Dr. James L. Adams, Hobart, has been appointed health superintendent of Kiowa County, and Dr. Harry B. Hall, Boise City, of Cimarron County. Dr. Robert M. Church, Stilwell, has been appointed to a similar position in Adair County.

PENNSYLVANIA

Hospital News.—Ground was broken for a new surgical unit to be constructed at the state tuberculosis sanatorium, Hamburg, April 27. The unit will be devoted to chest surgery and have accommodations for thirty-eight patients. The 1936 legislature appropriated \$150,000 for its erection.

Philadelphia

Memorial to Texas Physician.—A bronze tablet was placed in the interns' quarters of the Philadelphia General Hospital recently in memory of the late Dr. George E. Bethel, Galveston, Texas. The funds for the memorial were subscribed to by Texas physicians who have served as interns in the hospital, former classmates and friends. Dr. Bethel was intern and assistant chief resident from 1924 to 1926 and served as dean and professor of tropical medicine in the University of Texas School of Medicine from 1928 to 1935. He died April 17, 1935.

Dr. Bland Made Professor Emeritus.—Dr. Pascal Brooke Bland, professor of obstetrics at Jefferson Medical College, has been made professor emeritus and Dr. Norris W. Vaux, clinical professor of obstetrics, has been appointed to succeed him. Dr. Bland was born in Monocacy, Pa., in 1875 and graduated from Jefferson in 1901. The following year he joined the teaching staff of the school and, in 1925, became professor. He was formerly president of the Obstetrical Society of Philadelphia. Dr. Vaux, who is 56 years of age, graduated from the University of Pennsylvania School of Medicine in 1905.

Pittsburgh

Graduate Course.—The committee on graduate education of the Allegheny County Medical Society will offer a course on the diagnosis and treatment of syphilis, July 14, 21 and 28, under the direction of Dr. Lawrence G. Beinhauer. Instruction will be given in the technic of darkfield examination; differential diagnosis from common skin diseases; serologic

and spinal fluid evaluation and Wassermann-fastness. Lectures will outline the treatment of primary, secondary, tertiary, maternal and congenital syphilis, with instruction in the preparation and administration of all drugs currently used in treatment. Additional information may be obtained from the society, 5088 Jenkins Arcade.

WASHINGTON

Graduate Lectures.—The twenty-first annual course of medical lectures and clinics of the University of Washington will be presented July 19-23. Speakers will include:

Dr. Anton J. Carlson, professor of physiology, University of Chicago.
Dr. Hans Lissner, clinical professor of medicine, University of California Medical School, San Francisco.
Dr. William S. Middleton, professor of medicine, University of Wisconsin Medical School, Madison.
Dr. Waltman Walters, associate professor of surgery, Graduate School, University of Minnesota, Rochester-Minneapolis.

A fee of \$10 will be charged for the course. Additional information may be obtained from the extension service of the university at Seattle.

Society News.—At a meeting of the Spokane County Medical Society, May 13, in Spokane, Drs. Frederick LeMere, Medical Lake, discussed "Experiences with Insulin Shock" and George W. Pierce, San Francisco, "Reconstruction Surgery After Trauma."—The Washington State Obstetrical Association held its first semiannual meeting in Tacoma, April 13; the program was devoted to round table discussions on treatment of puerperal sepsis, contraction rings, anatomy of the bony pelvis and prenatal and postnatal care. The society was organized January 30 with Dr. Henry H. Skinner, Yakima, as president. The next meeting will be in October.—"Surgery of Congenital Defects" was the theme of the eighth annual meeting of the Tacoma Surgical Club, April 3; guest speakers were Drs. George C. Crile, Cleveland, Paul B. Magnuson, Chicago, and Gordon B. New, Rochester, Minn. Dr. Millard T. Nelsen, Tacoma, conducted a clinic on developmental anomalies of the face and neck.

WEST VIRGINIA

Dr. Van Liere Named Dean at West Virginia.—Dr. Edward J. Van Liere, since 1935 acting dean of the West Virginia University School of Medicine, Morgantown, has been appointed dean. A graduate of Harvard Medical School, class of 1920, Dr. Van Liere has been associated with West Virginia since 1922 as professor of physiology.

WYOMING

District Meeting.—The Natrona County Medical Society sponsored a district meeting in Casper, April 24-25. The house of delegates of the state medical society met during the session, since it voted in 1936 to forego its annual meeting this year to participate in the Rocky Mountain Medical Conference to be held in Denver, July 19-21. Addresses were delivered by Drs. Marshall C. Keith, Casper, secretary of the state medical society; William O. McDermott, Casper, president of the county medical society, and George P. Johnston, Cheyenne. Other speakers included:

Dr. Joseph C. Buntin, Cheyenne, Tumors of the Kidney.
Dr. Oliver E. Torkelson, Casper, Etiology of Cancer.
Dr. John R. Nilsson, Omaha, Neb., A Series of Hernia Cases.
Dr. Joseph F. Replogle, Lander, Legislative Experiences.
Dr. Joseph J. McGill, Casper, Schilling Hemogram as a Laboratory Aid in Diagnosis and Prognosis.
Dr. William Andrew Buntin, Cheyenne, Diseases of the Pituitary Gland from the Surgical Standpoint.
Dr. George M. Anderson, Cheyenne, Federal and State Endeavor in Relation to Eradication of Syphilis.

GENERAL

Examinations in Pediatrics.—The American Board of Pediatrics announces examinations will be held in the following cities:

Los Angeles, during a meeting of region IV of the American Academy of Pediatrics, in October.
Chicago, during a meeting of region III of the American Academy of Pediatrics, November 4-6.
Boston, during a meeting of region I of the American Academy of Pediatrics, November 12-13.
New Orleans, during a joint meeting of region II of the American Academy of Pediatrics and the Southern Medical Association, December 1-3.

Definite dates for these examinations will be published later.

National Health Meeting.—During the annual meeting of the National Education Association in Detroit, June 28-30, the department of school health and physical education will present a special program. Subjects to be discussed include "The Relationship of Extra-Curricular Activities to Health," "Training School Health Personnel" and "Urgent Problems in School Health Education—Venereal Disease, Alcohol and Narcotics, Traffic Safety and Sex Education." Dr. Isaac A.

Abt, professor of pediatrics, Northwestern University Medical School, Chicago, will address the dinner session Wednesday evening on "The Physician and the School Child."

International Health Congress.—The National Health Council and the World's Fair Advisory Committee on Medicine and Public Health are perfecting plans to hold an international congress on health during the New York World's Fair in 1939. The program will be related, as much as possible, to the exhibits on medicine and public health that will be on display at the fair and it is hoped that a permanent American Museum of Hygiene, similar to the German Hygiene Museum in Dresden, will be established in New York subsequently. According to the announcement, American and foreign specialists will be asked to deliver addresses on subjects of interest not only to professional groups but to the general public as well.

Airplane Company Institutes Control Measures Against Yellow Fever.—The vaccination against yellow fever of all flying personnel, not already vaccinated, of the Pan American Airways, Inc., was begun in April at the Rockefeller laboratory in Rio de Janeiro, as a control measure. Beginning May 1, the company also requires cards to be filled out for all passengers showing where they have been or have resided for the six days just prior to embarking en route to the United States. These cards are attached to the passenger list of the airplane and will be available to the quarantine officer on arrival at its destination. A recent investigation of the U. S. Public Health Service, when fifty-three insects were captured and one escaped in twenty-four of sixty-nine inspections, proved that airplanes may be considered a health hazard so far as the importation of yellow fever is concerned unless adequate control measures are instituted.

Association of Medical Women Change Name.—The Medical Women's National Association will in the future be known as the American Medical Women's Association in accordance with action taken at its annual meeting in Atlantic City, June 7. It was stated that this was in line with the policy being adopted by the organizations affiliated with the International Medical Women's Association. Dr. Mabel M. Akin, Portland, Ore., was elected president of the association. Other officers are Drs. Kate B. B. Karpeles, Washington, D. C.; Helen G. Dennis, Portland, Ore.; Florence R. Gilpin, New Orleans, vice presidents; Helen I. A. Cary, Portland, secretary, and Mary Riggs Noble, Philadelphia, treasurer. At this meeting announcement was made of a gift to the association of a large residence in Long Beach, Calif., for use of members who are suffering poor health or economic difficulties. Dr. Alice Barker-Ellsworth, Long Beach, was the donor.

Another Foundation for Medical Research.—The Dazian Foundation for Medical Research will be created and receive the bulk of his estate under the will of the late Henry Dazian, New York, it is reported. To be used for the advancement of medical or allied scientific knowledge and the establishment of fellowships, the will stipulated that the funds were to be awarded for the further education of individuals and for research and investigation by individuals or institutions not engaged for private gain or profit. The foundation is to be managed by nine members, five of whom shall be physicians: Drs. Emanuel Libman, Israel Strauss, Alexis Carrel, Philip Finkle, New York, and Harrison S. Martland, Newark, N. J. The four lay members are Alfred L. Rose, Harold Williams, Emil Friedlander and Mr. Dazian's nephew, William W. Cohen. The will directs that twenty-five years after his death the principal of the trust be distributed to such hospitals, sanatoriums or similar institutions as the board shall determine.

Society News.—The Biological Photographic Association will hold its annual meeting in Rochester, N. Y., September 23-25.—Dr. Russel H. Patterson, New York, was chosen president of the American Society of Regional Anesthesia at its meeting in New York, April 20; vice presidents are Drs. Hyman Lieber, New York; Henry S. Ruth, Philadelphia, and Brian C. Sword, New Haven, Conn., and Dr. Paul M. Wood, New York, was reelected secretary. They will assume office July 1.—Dr. John Hamilton Crawford, Brooklyn, has resigned as editor of the *Bulletin* of the American Heart Association and has been succeeded by Dr. Lucy Du Bois Porter Sutton, New York.—Dr. Isidore Friesner, New York City, was chosen president-elect of the American Otolological Society at its annual meeting, May 8, and Dr. Harris P. Mosher, Boston, was installed as president. Dr. Thomas J. Harris, New York City, was reelected secretary. The next annual meeting will be in Atlantic City.—At a meeting of the American Gynecological Society in May, Dr. Noble Sproat Heaney, Chicago, was elected president, and Dr. Richard W.

TeLinde, Baltimore, was reelected secretary.—Dr. Harold Brunn, San Francisco, was chosen president-elect of the American Association for Thoracic Surgery at its annual meeting, June 1, and Dr. Stuart W. Harrington, Rochester, Minn., was installed as president. Dr. Richard H. Meade Jr., Philadelphia, was reelected secretary. The next annual session will be held in Atlanta, Ga., the date to be determined later.—Dr. John F. Barnhill, Miami Beach, was elected president of the American Laryngological Association at its annual meeting, May 31, and Dr. James A. Babbitt, Philadelphia, was reelected secretary.—At the annual meeting of the National Tuberculosis Association, June 2, Dr. Jay A. Myers, Minneapolis, was elected president, and Dr. Charles J. Hatfield, Philadelphia, reelected secretary. The next annual meeting will be in Los Angeles, June 20-23, 1938.—Mr. James F. Ballard, Boston, was chosen president of the Medical Library Association at its annual meeting, May 24, and Miss Janet Doe, New York, was reelected secretary. The next annual session will be in Boston.—At the annual meeting of the American Academy of Pediatrics in New York, June 4, Dr. Henry F. Helmholz, Rochester, Minn., was named president-elect and Dr. Philip Van Ingen, New York, was inducted into the presidency. Dr. Clifford G. Grulee, Evanston, Ill., is secretary.—Dr. Walter R. Steiner, Hartford, Conn., was elected president of the American Association of the History of Medicine at its annual meeting in Atlantic City, May 3; Dr. Esmond R. Long, Philadelphia, vice president, and Dr. Edward J. G. Beardsley, Philadelphia, secretary, reelected. The next annual session will also be held in Atlantic City in May.—Dr. Richard H. Hutchings, Utica, N. Y., was chosen president-elect of the American Psychiatric Association at its annual meeting in Pittsburgh, May 10-14, and Dr. Ross M. Chapman, Towson, Md., was installed as president. Dr. William C. Sandy, Harrisburg, Pa., was reelected secretary.

Monument to X-Ray Martyrs.—A recent issue of *Radiography and Clinical Photography* lists the names of American x-ray martyrs that appear on a monument erected last year by the German Roentgen Society before the Roentgen Institute of St. George's Hospital, Hamburg, Germany. The monument is a four sided shaft of stone bearing on one side the following epitaph:

To the Roentgenologists, and Radiologists of all nations—doctors, physicians, chemists, technicians, laboratorians and nurses—who sacrificed their lives in the struggle against the diseases of mankind. They were heroic pioneers who made possible the successful and safe use of roentgen and radium rays in medicine.

Immortal is the Glory of the Work of These Dead.

Following is the list of Americans included in the 160 names on the monument:

Robert Abbe, New York
Frederick H. Baetjer, Baltimore
Burton E. Baker, Hartford, Conn.
John Bauer, Hartford, Conn.
Thomas J. Buchanan, Philadelphia
Eugene W. Caldwell, New York
Clarence Dally, East Orange, N. J.
Walter J. Dodd, Cambridge, Mass.
Lewis M. Early, Columbus, Ohio
William C. Egelhoff, Chicago
Elizabeth Fleischman, San Francisco
Robert Friedlander, Chicago
Wolfram C. Fuchs, Chicago
Stephen C. Glidden, Danville, Ill.
Henry Green, Hartford, Conn.
Judge Hough, New York
Mihran H. Kassabian, Philadelphia
Edmund C. Kells, New Orleans
William Krauss, Memphis, Tenn.
Louis A. Weigel, Rochester, N. Y.

John A. Lee, Brooklyn
Charles L. Leonard, Philadelphia
William C. Lyle, Lynchburg, Va.
Robert H. Machlett, New York
John McIntosh, Chicago
S. H. Monell, New York
James T. Morehouse, Newark, N. J.
Lawrie B. Morrison, Boston
Gardner Parker, Pocatontos, Iowa
John Pitkin, Buffalo
Heber Roberts, Belleville, Ill.
F. L. R. Satterlee, New York
Ira Simms, New York
William B. Snow, New York
Frank H. Sweet, Boston
Benjamin F. Thomas, Columbus, O.
Charles H. Viol, Pittsburgh
Rome V. Wagner, Chicago
Thurman Wagner, Chicago

FOREIGN

Harben Gold Medal Awarded.—The council of the British Royal Institute of Public Health has awarded the Harben Gold Medal to Sir Frederick Edward Gowland Hopkins, professor of biochemistry, University of Cambridge, according to *Science*. The medal is awarded triennially under a trust created by the late Sir Henry Harben "to the person, irrespective of nationality, who, in the opinion of the council, has rendered the most eminent services to public health."

No Yellow Fever in Hongkong.—THE JOURNAL, May 29, printed a news item reporting two cases of yellow fever in Hongkong, which was credited to the *Chicago Tribune*. We are informed by the U. S. Public Health Service that these two cases of yellow fever were incorrectly diagnosed as such by Hongkong health authorities. A postmortem examination of one of the cases which proved fatal showed the disease to be leptospirosis, an infectious jaundice which is stated to be common in the Orient. The similarity in the symptoms between leptospirosis and yellow fever was the reason for the error. The original story in the *Tribune* was an Associated Press dispatch.

The British Medical Association and the Nostrum Evil

In a memorandum submitted to the select committee of the House of Commons on Medicine Stamp Duties, the British Medical Association has reviewed its endeavors to combat the danger to public health from the unrestricted advertisement and sale of patent medicines. In the early years of the present century the association published a series of analyses of popular remedies with the object of showing their worthless nature and the trivial cost of preparations for which the makers made exaggerated claims and which they sold at exorbitant prices. In evidence submitted to the Select Committee on Patent Medicines appointed in 1912 the association advised the publication on each packet of medicine of the name and quantity of each of the constituents, the application of the Food and Drugs Acts to proprietary medicines, and the institution of legal proceedings against offenders. Pending the adoption of such a measure by the government, the association has performed a considerable amount of educational work with success by getting the more responsible newspapers and periodicals to reject objectionable or misleading advertisements.

The objections of the association to the uncontrolled advertisement and sale of patent medicines rest mainly on the dangers which arise from self diagnosis and self treatment. The lay person has not the knowledge to evaluate his symptoms and diagnose his complaint; neither can he know whether the remedy offered is that required for his individual condition. The patent medicine is offered as a stock treatment for all sorts of patients regardless of their individual peculiarities. It is also offered for a host of dissimilar conditions. Moreover, the proper treatment of disease requires early diagnosis. While the patient is taking the patent medicine he is losing valuable time. The delay is particularly serious in certain diseases. The association has therefore endeavored to secure the prohibition of the sale, in the absence of a prescription from a physician, of remedies alleged to cure or relieve Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxia, lupus, paralysis, amenorrhea, hernia, blindness and any ailment of the auditory system.

English and German University Celebrations

In a previous letter (*THE JOURNAL*, April 18, 1936, p. 1402) was reported the refusal of the English universities and learned societies to attend the celebration of the University of Heidelberg because of the political intolerance which emptied the German universities of many of their most eminent teachers. Göttingen University is to celebrate its bicentenary June 20 and Oxford University has again refused to attend. Whether the mistake of sending invitations was again repeated this year in the case of the other English universities has not transpired. As in the case of Heidelberg, the anomaly of celebration under the circumstances has aroused criticism in the press.

The scientific journal *Nature* says that probably no university preserved so high a standard over so long a period as Göttingen. Among its professors were Haller (a Swiss), the first modern physiologist, Gauss, the eminent mathematician, astronomer and experimenter, Blumenbach, the father of anthropology, the brothers Grimm, the begetters of philology, and Henle, the founder of histology. After the war the mathematicophysical group there formed the most important scientific school in Germany. But in 1933 a change occurred. A great number of the library books were burned without any protest from the rector. In 1934 came "the clean up," when

many of the most eminent teachers were expelled. "We got rid of what was outworn and superfluous in the university," said the minister of education. It is curious to recall some of the men to whom he applied these adjectives. They included 1. Professor Bernstein, who had been on the staff for twenty-five years and was director of the Institute of Mathematical Statistics. He now holds a chair at Columbia University. 2. Professor Born, famous for his work on the quantum theory. He now holds a chair at Edinburgh. 3. Professor Courant, chief organizer of mathematical research, now professor at New York. 4. Professor Franck, who won the Nobel prize in physics. On resigning he wrote that he could not remain silent while his colleagues were being dismissed. This drew an abusive "protest" from thirty-three professors and teachers.

In all, twelve professors have been displaced, of whom five now hold chairs in America and one each at Edinburgh, Oslo and Copenhagen. The total losses to the German universities and seats of higher learning amount to 1,684 teachers expelled. In addition there are quiet resignations, which must bring the total up to 2,000. The excited and threatening atmosphere in which work is now carried on is inimical to science. It is therefore not surprising that estimates are unanimous in finding a rapid and continuous fall in quality. *Nature* concludes: "Göttingen ceased in 1933 to be a scientific center. On June 30th visitors will celebrate a unique series of losses of learning, liberty and life."

PARIS

(From Our Regular Correspondent)

May 22, 1937.

Periodic Examination of Chauffeurs

Examinations at intervals are now required of all chauffeurs of taxis and motor trucks. This ought to be extended to those who drive their own cars and to chauffeurs of private cars. Intoxication is one of the most frequent causes of accidents. There are two types of drunken drivers, the one who is a chronic alcoholic and the other a so-called Sunday drunkard, who restricts his excesses to holidays in general. To make a distinction between these two forms of intoxicated chauffeurs, the Academy of Medicine of Paris has asked that every automobilist, whether he drives his own or some one else's car, should carry a "route book" in which every accident shall be inscribed. This would be of great aid to the courts in a search for the person responsible for an accident.

A single examination for a driver's license does not suffice. A person who has been examined at the age of 20 or 25, or even 30 years, and found fit to drive may not be so ten years later. Latent or acquired syphilis may be rapidly followed by tabes or dementia paralytica. Aortitis that could not be detected when the applicant was first examined may be the cause of sudden death at the wheel later on. A chauffeur who was not an alcoholic addict when first examined may acquire this vice ten years or more after his license tests. As one grows older, both vision and hearing change; hence these should be checked up.

The periodic examination of all chauffeurs is the subject of an article by Bzowski in the Dec. 20, 1936, *Journal de médecine de Bordeaux*, in which the following order of frequency of periodic examinations is suggested: between the ages of 20 and 35 years, every five years; between 35 and 50, every three years; between 50 and 60, every two years; above 60, every year. In the case of any person who has had syphilis, the same method should be adopted as in Germany and certain French insurance companies, to consider the age of the applicant as being advanced by five years. A chauffeur 46 years of age would be considered as being 51 years old and hence subject to reexamination every two years. The finding of some physical or mental defect does not mean permanent rejection but is subject to revision after a certain period; in the case of a mitral lesion, one year.

Defects can be grouped as (1) physiologic, (2) technical or (3) psychologic. The medical examination aims to evaluate the first of these, and the severity of mechanical tests the second. For the third group, a series of psychomotor and emotion reaction tests were devised by Gamus, Netter and Binet for the examination of air pilots during the World War. The reaction time was measured by the d'Arsonval electric chronometer. The effect on the nervous system caused by a revolver shot was measured by the graphic methods employed in experimental physiology for estimating changes in cardiac and respiratory rhythm, vasomotor system and muscular twitching. Although the psychomotor reactions are reliable, the same cannot be said of the emotional reactions, which are of a more complex nature.

After every accident, a chauffeur ought to be subjected to a general medical examination and the reaction time again tested.

The administration of the Paris omnibus system employs the following tests before employing chauffeurs. Any visitor can verify the necessity of quick reflexes when a large bus twists in and out of the narrow streets in some portions of the city. In this company's tests the applicant is placed on a platform, which is furnished with all the equipment that he will find on a bus. A film is projected in front of him, which includes every possible incident and accident, such as a pedestrian trying to cross in front of the bus, or a vehicle suddenly coming out of a side street. The original feature of the film is that it is put into motion or stopped by the applicant himself when he manipulates the clutch, steering wheel and brake. The faster he runs, the more rapidly does the film turn, and vice versa. The signals to stop or start are registered on a drum under control of the examiner simultaneously with the various incidents and accidents of the film which the applicant has encountered. As a result, one obtains an accurate graph of the reactions of the applicant.

Bzowski believes that this method of examining applicants for the position of chauffeur of Paris busses ought to be extended to all persons who have occasion to run a vehicle carrying more than eight passengers as well as for all taxi chauffeurs. As to other automobilists, a minimum examination ought to include obligatory general medical examination and the psychotechnical tests after every serious accident. If these show incapacity to conduct an automobile, the medical examiner should have the right to have the driving license canceled. There are many cyclists on the routes in France and other European countries. Failure to show a red light on the rear of the machine at night is a frequent cause of fatal accidents here. Speed laws are but little enforced in France, and motorcycle policemen on the routes are few and rarely seen. Visitors to Paris and other large cities often wonder why there are not more accidents when one has the opportunity to note the speed with which automobiles, especially taxis and busses, are allowed to run.

Deficit in Social Insurance Budget for 1935

Dr. Dordives in the May 1 issue of the *Siècle médical* gives some statistics regarding the social insurance budget for 1935. Receipts were 1,188 million francs; expenditures (including 26 million turned over to the guaranty fund) were 1,253 million francs. The figures for 1936 are not yet published, but it is known that there have been a smaller number of insured during 1936, owing to the large number of unemployed. In addition, the premium rate was reduced, so that the deficit for 1936 will probably exceed that of 1935.

Familial Icterus Cured by Blood Transfusions

Recovery from familial icterus of the new-born is so rare, according to Péhu, Noel and Brochier of Lyons, that they reported a case at the March 23 meeting of the Académie de médecine de Paris. The family history was as follows: There had been five children, a girl now 7 years old in good health,

a second baby who died on the fourth day of icterus, a third child who had an intense icterus at birth, followed by a nervous syndrome (nuclear icterus) with retarded intelligence, and who died at the age of 3½ years. The fourth child also had an icterus five hours after birth. This baby recovered following three intragluteal injections of citrated blood from a universal donor. Icterus appeared at the end of the first day in the fifth child, became progressively more intense, and was accompanied by palpable enlargement of the liver and spleen. Recovery also followed the use of citrated blood from a universal donor.

Influence of Sterilization Law on Admissions to Psychiatric Institutions

The law for the prevention of hereditarily diseased offspring (THE JOURNAL, Sept. 9, 1933, page 866) has been in effect for several years, and an investigation of its influence on the admission material of institutions for the treatment of mental disorders should be of interest. Three serious hereditary diseases are readily recognized; these are congenital feeble-mindedness, chronic alcoholism and hereditary epilepsy. In cases of any of the foregoing, relatives find it extremely difficult to prevent commitment, since so many unequivocal manifestations of these disorders are apt to occur outside the home. As to schizophrenic patients, numerically the most formidable category, it seems easiest to convince the relatives of such persons that it is a question of mental disease, the severe manifestation of which necessitates hospitalization. Milder cases, treated polyclinically, are perhaps less likely to be hospitalized. Moreover, many schizophrenic persons are for long regarded as merely psychopathic. The depressive patient offers the most difficult problem. The term "depressive" is applied to many schizophrenic patients in addition to the true depressive types. In depressive cases relatives are often loath to realize that it is a question of psychosis.

It is interesting to see how these general observations are specifically reflected in the statistics of the Munich Psychiatric Clinic. The total number of admissions has undergone no important change; it has slowly increased for patients of both sexes. If only patients of tainted heredity are considered, however, a manifest decline is observed to have taken place during 1934: among the men from 462 to 394, among the women from 560 to 436; namely, declines of from 32 to 26 per cent and from 50 to 42 per cent, respectively. In 1934, to be sure, the Eugenics Court ordered no hospitalizations. With promulgation of the new legislation the number of admissions of cases in the first named triad of disorders (feeble-mindedness, alcoholism and epilepsy) declined, then rose suddenly for both sexes in 1935; namely, from one-third to two and one-half times that of the previous year. The increase in the number of male patients continued into 1936. For schizophrenic patients the percental proportion remained unchanged. The figures for depressive patients were the most noteworthy: the number of men patients sank from sixty-nine in 1932 to twenty-nine in 1935; that is, by more than 50 per cent. The same trend was noted among women patients excepting that here the maximal figure (117) was much higher, thus reflecting the greater incidence of depressive insanity among women. Admissions of patients presenting schizophrenia, socially the most important and most frequent hereditary disorder, have on the whole not fallen off. Feeble-mindedness and alcoholism are more easily recognized than in former years. On the other hand, a greater proportion of depressive patients seemed able to elude proper hospitalization. Whether these persons remain at home or are diverted to other institutions under a false diagnosis of neurasthenia, it is impossible to say.

The German Society of Research on Circulation

The convention of the German Society of Research on Circulation was held at Bad Nauheim. Sir H. H. Dale of London first spoke on vasodepressor substances. He considered especially the rôle of histamine. This substance is liberated by nervous stimulation of the tissues and dilates the vessels of the working musculature. It is not present in free form in the blood but only in an inactive compound and it is probably contained in the leukocytes in a rudimentary form. Liberated acetylcholine has no share in the vasodilatation. It is as quickly destroyed as produced and for this reason is principally found in isolated organs. Cholinergic and adrenergic nerves must be differentiated. The vasodilator substances appear as a consequence of muscular contraction within the musculature proper. Thus far it has not been determined with certainty which substances produce a vasodilatation.

Hermann Rein, Göttingen physiologist, read a paper on epinephrine and kindred substances. Epinephrine does not circulate within the organism in as large quantities as one is inclined to concede but in much smaller measure. These small quantities of epinephrine secreted by the adrenals regulate circulation without exerting any influence on the blood pressure and guarantee an optimal distribution of blood. Each vessel may exhibit a different reaction to epinephrine. The nature of the reaction will depend on the condition of the organism; thus, for example, epinephrine will dilate the vessels in working muscles. The metabolic products elicited by muscular activity alter the vascular capability of reaction to epinephrine. The dosages of epinephrine usually employed in pharmacologic and therapeutic practice are far too high and unphysiologic. By means of a new substance, 1-para-oxyphenyl-2-methyl-ethyl-aminopropane, which represents a reduction product of epinephrine, Rein was able to maintain only the regulatory action of the latter substance without the deleterious action.

Among other papers read, Raab of Vienna discussed "The Suprarenal Glands and Angina Pectoris." Muscular exertion, mental excitement and cold are conducive to attacks of angina pectoris. This mechanism takes place by means of the elimination of epinephrine. By restriction of adrenal function the susceptibility to attacks of this sort is substantially reduced, and eventually the condition is cured. Raab accordingly subjects the adrenal glands to roentgen irradiation.

Schenk of Danzig discussed circulation of the blood at the menopause. The remission of sex hormone in old age is the occasion for a stimulation of the anterior lobe of the hypophysis; secondarily the excitation of the thyroid and adrenals thus produced results in the pathologic symptoms of the climacteric. In men there appear as characteristic changes in the voice, in sexuality and fatigability as well as complaints indicative of coronary insufficiency. Muscularly strong types are above all affected.

The New Roentgen Center

A "Roentgen Bureau" has just been established at Munich by the German Roentgen Society. It represents the realization of a long cherished ideal. The function of this center will be to build up a library collection which will cover the entire field of radiology. It will also house much helpful supplementary material and a card catalogue of works on general and specific topics related to radiology. Provision has also been made for a museum collection of radiologic and kindred apparatus to illustrate the historical development of the field. The building up and completion of the collections is in charge of the recently created Roentgen Memorial Foundation. All the work of acquisition and cataloging will be supervised by this body. The honorary officers of both library and museum are appointed by the head of the German Roentgen Society. The library and other collections are already established and in use. Ample facilities for study and reference make the material readily accessible to the research worker.

May 15, 1937.

Fracture of Neck of Femur

Professor Galeazzi, head of the Clinica Ortopedica e Traumatologica of the Milan University, in a lecture to the physicians of the army spoke on fractures of the neck of the femur. According to the speaker, healing of fractures of the neck and consolidation of the fracture with bone callus formation, with consequent functional recovery of the limb, can be attained by means of a well conducted treatment based on an exact diagnosis of the type of the fracture, of which there are four: subcapital fracture of the femur, that is, between the head and the neck; an intermedian fracture which, as a rule, is oblique, and the petrochanteric and lateral fractures. Fractures of the upper part of the femur run to the base of the neck or through the trochanter and are benign in two thirds of the cases. In the other third the fractures run through the neck and frequently are subcapital. Many surgeons resort to traction by weights in the treatment of subcervical and petrochanteric fractures. Others, believing that fractures of the neck do not heal in the elderly, leave the patient to his fate with a non-treated fracture, of which not even roentgenograms are taken. According to the speaker, satisfactory results are obtained in petrochanteric and lateral fractures at the base of the neck from continued longitudinal traction with weights. The limb is maintained in constant abduction and internal rotation. This method of treatment demands constant supervision of the surgeon and the application of technical refinements. In the treatment of intermedian and subcapital fractures, the treatment depends on the exact knowledge of the displacement of the fragments, which is obtained by the study of three roentgenograms, two of which are taken in the frontal view and the other one in the sagittal view of the neck in relation to the axis (the so-called axial roentgenogram). Intermedian fractures have a tendency to remain in insufficient consolidation. Lateral fractures heal more easily than the intermedian. Complicating pseudarthrosis in these cases, especially in the elderly, originates in insufficient blood supply to the head of the femur. The latter, according to Schmore, is not due to obliteration of the vessels of the round ligaments, from sclerosis of the vessels. It is due to occlusion of the vessels by the displacement of the fractured fragments. In order to consolidate the fracture, the perfect adjustment of the surfaces of the fractured bone is important and can be obtained by the use of a plaster cast, by the application of Whitman's method of prolonged immobilization or by direct union of the fragments. Whitman's method is based on the examination of the mechanical condition of fractures of the neck. It is of value except in the elderly and in abnormal persons, in whom it is contraindicated because of the necessary immobilization for at least six months. Modern surgeons operate in recent fractures of the neck. Fixation of the fracture by the Smith-Petersen pin, by which the surfaces of the fragments are held in contact in the correct position for as long as it is necessary to obtain consolidation, is generally preferred. Johansson's extra-articular technic for fixation of the fracture with a nail is the ideal operation in fractures of the neck, even if old, as well as in pseudarthrosis, provided there is a normal blood supply of the head of the femur and a normal head. Alterations in the segment of the head from insufficient blood supply are shown in the roentgenogram of the head by a shadow darker than that of the surrounding decalcified bone tissues. In certain favorable forms of pseudarthroses, Pauwels' subtrochanteric cuneiform osteotomy gives satisfactory results. The operation is done by placing a nail in the greater trochanter and another at the diaphysis, which serve the purpose of showing the direction of the fragments after osteotomy. The operation results in an inclination of the plane of the pseudarthrosis, with correction of the condition.

Society Reunion

The Accademia delle Scienze Mediche e Chirurgiche met recently at Naples under the chairmanship of Professor Jappelli. Professor Ora reported results of experiments to determine the efficacy of the oral administration of bismuth for the prevention of syphilis. Out of a group of thirty-five rabbits which were given a bismuth preparation (Bismutrat) orally, only seven lived long enough to show the results of the experiment. In two of the surviving rabbits syphiloma developed to the extent that spirochetes were injected, while in the other five popliteal adenopathies developed. In one rabbit, given large doses of bismuth compound for a long time, bismuth poisoning appeared and syphilitic adenopathy also developed. The speaker stated that bismuth fails to protect the animals against syphilis if it is administered by mouth, even if it is given in large doses.

Professor Repetto reported results of experimental vesical mycosis in rabbits, which were placed in three groups. A suspension of fungi was directly instilled in the bladder of the animals in the first group, injected in the renal parenchyma by the lumbar route to those of the second group and intravenously administered to those in the third group. Vesical stasis was induced from a few hours to a week after the injections. Chemical and microscopic examinations of the urine were made in all cases, and cultures with the sediment of the urine, which was withdrawn with a catheter, were prepared. Groups of animals, containing those of the first, second and third groups in the experiments, were killed on the fifteenth, thirtieth, sixtieth and ninetieth days after inoculation, respectively. In all cases the histologic examination of the bladder was made. It was found that the bladder presents resistance to the fungous infection, even if favorable conditions for the development of fungi such as the presence of vesical stasis or of injected dextrose are created. Direct inoculation of fungi to the bladder is the easiest route of infection. The intravenous and descendent renal routes, as a rule, fail to cause vesical mycosis. The anatomopathologic lesions are not diffused. As a rule, they become encapsulated and follow a process of spontaneous resolution.

Deaths

Prof. Achille Monti, professor emeritus of pathologic anatomy of the Pavia University, is dead. He was a pupil of Golgi, Kock and Weichselbaum. He wrote works on epidemic jaundice and did important work in preventing malaria in Italy, especially by improving the living conditions of the people.

General Dr. Luigi Montanari of Parma died recently in that city at the age of 104. He wrote important articles on fatigue, which were reviewed and developed by the physiologist Dr. Angel Mosso. Dr. Montanari's mind was completely lucid all through the last years of his life, during which he had the same interest in science as he had in previous years.

Marriages

CRAIG WRIGHT MUCKLE, Haverford, Pa., to Miss Christine Murdoch Kendrick of Philadelphia, June 3.

DEVEAUX BLAIR SULOUFF, New York, to Miss Marguerite Elizabeth Graybill of Roanoke, Va., May 8.

THOMAS F. HARMON, Springfield, Ill., to Miss Eleanor Virginia Colley, of Oklahoma City, May 12.

STEPHEN STOCKTON WOOLSTON to Miss Elizabeth Vaux Ingersoll, both of Philadelphia, June 5.

JAMES A. ROGERS to Miss Olivia M. Dunican, both of Rockville Centre, N. Y., June 3.

HELEN L. MILLER, New York, to Mr. Alexander F. Armstrong of Albany, June 2.

EDWIN M. BUTLER, Centerville, Miss., to Miss Redolia Davis of Atlanta, Ga., May 5.

Deaths

George Aloysius Leitner @ Piermont, N. Y.; Bellevue Hospital Medical College, New York, 1888; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association, 1925-1935; visiting surgeon to the Nyack (N. Y.) Hospital and the Rockland County Tuberculosis Hospital, Pomona Park; surgeon to the Letchworth Village, Thiells, and Rockland State Hospital, Orangeburg, and consultant to the Good Samaritan Hospital, Suffern; health officer of Hudson Valley and eight villages and townships in that area; aged 71; died, May 18, in the Harkness Pavilion of the Columbia-Presbyterian Medical Center, New York.

Edwin Albert Spies, New York; Fordham University School of Medicine, New York, 1910; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; adjunct professor of orthopedic surgery at the New York Polyclinic Medical School and Hospital; served during the World War; visiting surgeon, in charge of skeletal surgery, Morrisania City Hospital; visiting orthopedic surgeon to the Misericordia Hospital; consulting orthopedic surgeon to the Westchester Square Hospital, New York, and St. Francis Hospital, Poughkeepsie; aged 49; died, March 22, at his home in Pelham, of chronic nephritis and coronary thrombosis.

James John Quiney @ Easton, Pa.; Jefferson Medical College of Philadelphia, 1903; past president and secretary of the Northampton County Medical Society; member of the American Roentgen Ray Society, the Radiological Society of North America and the American College of Radiology; formerly health officer of Easton; chief roentgenologist to the Easton Hospital; formerly on the staff of the Warren (Pa.) Hospital; aged 55; died, March 31, of coronary sclerosis and hypertension.

George Edward Potter @ Detroit; Detroit College of Medicine, 1896; fellow of the American College of Surgeons; director of the Harper Hospital Polyclinic, 1907-1908; clinical assistant to chair of surgery, 1908-1911; clinical professor of urology, 1911-1914, and associate clinical professor of surgery, 1914-1921, Detroit College of Medicine and Surgery; on the staff of the Providence Hospital; aged 64; died, March 16, of lobar pneumonia.

Willard Eugene Smith, Wilmington, Del.; Jefferson Medical College of Philadelphia, 1899; member of the Medical Society of Delaware; formerly member of the city board of health; member of the staff of the Physicians and Surgeons Hospital, now known as the Wilmington General Hospital, of which he was formerly chairman of the medical board; aged 72; died, March 23, of cardiovascular renal disease.

Lynn Gray Taylor @ Kansas City, Mo.; Western Reserve University Medical Department, Cleveland, 1882; formerly professor of neurology at the University of Kansas School of Medicine, professor of physiology at the Western Dental College and professor of physiology at the Kansas City College of Pharmacy; aged 77; died, March 31, of thyrotoxicosis and arteriosclerosis.

Frederick Ellsworth Sutherland @ Janesville, Wis.; Chicago Homeopathic Medical College, 1903; Northwestern University Medical School, Chicago, 1908; formerly secretary of the Rock County Medical Society; served the Mercy Hospital in various capacities; aged 58; died, March 20, of bronchopneumonia, coronary sclerosis and cardiac asthma.

Edward Roberts Plank @ Carlisle, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; president and for many years a member of the board of health of Carlisle; served during the Spanish-American and World wars; aged 57; on the staff of the Carlisle Hospital, where he died, March 13, of lobar pneumonia.

James Theodore Redwine @ Wahjamega, Mich.; Beaumont Hospital Medical College, St. Louis, 1900; past president of the Tuscola County Medical Society; superintendent of the Michigan Farm Colony for Epileptics; aged 61; died, March 16, in the University Hospital, Ann Arbor, of heart disease.

Arthur William Wermuth, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; member of the Illinois State Medical Society; aged 47; on the staff of the Ravenswood Hospital, where he died, April 17, of coronary occlusion and bronchopneumonia.

John Decamp Winter, Wynne Wood, Okla.; University of Nashville (Tenn.) Medical Department, 1909; member of the Oklahoma State Medical Association; served during the

World War; aged 51; died, March 9, in the Veterans Administration Facility, Muskogee, of carcinoma of the stomach.

Joseph Shackelford Stephens ☉ Natchitoches, La.; Tulane University of Louisiana Medical Department, New Orleans, 1885; formerly member of the state board of health, and president of the parish school board; aged 76; died, March 27, of arteriosclerotic heart disease and nephritis.

Manuel Daniel Rojas y Delgado, Puerto Castilla, Honduras, Central America; Tulane University of Louisiana School of Medicine, New Orleans, 1917; fellow of the American College of Surgeons; medical superintendent for the United Fruit Company; aged 48; died, March 8, of gunshot wounds.

Arthur Foster McCormick ☉ Falls Creek, Pa.; Jefferson Medical College of Philadelphia, 1903; served during the World War; aged 59; formerly in charge of the x-ray and laboratory department of the Maple Avenue Hospital, Du Bois, where he died, March 5, of myocarditis and hypertension.

George Clark Rublee, Rochester, N. H.; University of Vermont College of Medicine, Burlington, 1906; member of the New Hampshire Medical Society; served during the World War; on the staff of the Frisbie Memorial Hospital; aged 54; died, March 31, of cerebral hemorrhage.

Earle Francis Prior, Cochituate, Mass.; Tufts College Medical School, Boston, 1924; member of the Massachusetts Medical Society; served during the World War; formerly city physician of Malden; aged 39; was found dead, March 4, of carbon monoxide poisoning.

William Milton Rathgeber, Newark, N. J.; Long Island College Hospital, Brooklyn, 1923; member of the Medical Society of New Jersey; aged 40; was found dead, March 21, in his garage at East Orange, of accidental asphyxiation due to an automobile exhaust.

John J. Wakefield, Bloomfield, Ky.; University of Louisville Medical Department, 1876; member of the Kentucky State Medical Association; aged 84; died, March 23, in St. Joseph Infirmary, Louisville, of injuries received when he was struck by an automobile.

Richard Frank Tomlinson, San Francisco; Hahnemann Medical College, San Francisco, 1900; member of the California Medical Association; fellow of the American College of Surgeons; visiting surgeon to the Children's Hospital; aged 63; died, March 13.

Harriet Mary Wiley Whitney, Ashland, O.; Laura Memorial Woman's Medical College, Cincinnati, 1897; member of the American Psychiatric Association and the New England Society of Psychiatry; aged 62; died, March 25, in a hospital at Wrentham, Mass.

William Richard Hunt ☉ Clarksville, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1884; president of the Johnson County Medical Society; formerly on the staff of the Johnson County Hospital; aged 73; died, March 30.

Augustus Henry Hayden, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1888; for many years a member of the state board of health; aged 77; died, March 29, in a local hospital, of arteriosclerosis and nephritis.

Harriet Elizabeth MacSorley, Miami, Fla.; Maryland Medical College, Baltimore, 1912; formerly a practitioner in Philadelphia; aged 56; died, March 17, in a hospital at Venice, Fla., of surgical shock, following an operation for hip reconstruction.

Max Overton Usrey, Blytheville, Ark.; Kentucky School of Medicine, Louisville, 1907; member of the Arkansas Medical Society; served during the World War; formerly city health officer; aged 54; died suddenly, March 29, of angina pectoris.

Ira Hurst ☉ Parksley, Va.; University of Virginia Department of Medicine, Charlottesville, 1904; served during the World War; aged 57; died, March 28, in the United States Marine Hospital, Baltimore, of carcinoma of the liver.

Benjamin Charles Klein, Chicago; Rush Medical College, Chicago, 1936; intern at the Hospital of St. Anthony de Padua; aged 26; died, March 27, in St. Cloud, Minn., of Addison's disease, pulmonary edema and heart disease.

George Timothy Joyce ☉ Rochester, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; aged 57; died, March 29, in St. Mary's Hospital, of coronary occlusion.

Sterling Price Rumph ☉ Baird, Texas; Memphis (Tenn.) Hospital Medical College, 1904; Jefferson Medical College of Philadelphia, 1905; county health officer; aged 57; died, March 13, in a hospital at Cisco, of heart disease.

Calvin B. West, Jamesville, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; aged 69; died, March 19, in a hospital at Syracuse, of arteriosclerotic heart disease.

Clifford Walter Sumner ☉ Granville, N. Y.; Albany (N. Y.) Medical College, 1902; served the Emma Laing Stevens Hospital in various capacities; aged 62; died, March 19, of cerebral hemorrhage.

Harry Crawford Wayble, St. Bernard, Ohio; Medical College of Ohio, Cincinnati, 1904; served during the World War; aged 56; died, March 17, in the Christ Hospital, Cincinnati, of lobar pneumonia.

Harry Herbert Postle ☉ Newark, Ohio; Starling Medical College, Columbus, 1896; served during the World War; on the staff of the Newark Hospital; aged 63; died, March 21, of coronary thrombosis.

Frank Lee Niles, Wood Ridge, N. J.; Columbia University College of Physicians and Surgeons, New York, 1914; aged 53; school physician; died, March 26, of poison, self administered.

Orville Jay Richardson, Manifest, La.; Tulane University of Louisiana Medical Department, New Orleans, 1907; aged 51; died, March 29, in the Ferriday (La.) Hospital, of heart disease.

Edgar Morris Watson, Washington, D. C.; Howard University College of Medicine, Washington, 1936; aged 25; intern at the Freedmen's Hospital, where he died, March 9, of pneumonia.

Harry Griffin Sanders, Burgin, Ky.; University of Louisville Medical Department, 1893; formerly member of the state legislature; aged 68; died, March 30, of cerebral hemorrhage.

Ernest Walter Tonkin, Niles, Mich.; Detroit College of Medicine, 1895; member of the Michigan State Medical Society; aged 66; died, March 28, of coronary thrombosis.

Melancthon Braham Snyder, Council Bluffs, Iowa; University of Michigan Homeopathic Medical School, Ann Arbor, 1887; aged 80; died, March 31, of carcinoma of the colon.

Michael Servetus Seip, Easton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1876; aged 89; died, March 18, in the Betts' Private Hospital, of senility.

Frank Burton Sanford ☉ Canton, N. Y.; Albany (N. Y.) Medical College, 1893; since 1928 health officer of the village of Canton; aged 65; died, March 4, of angina pectoris.

Caryl Fenelon Seely White, Guilford, Conn.; Yale University Medical School, New Haven, 1881; aged 80; died, March 3, of mitral regurgitation and acute nephritis.

Harlan Lewis Smith ☉ Sacramento, Calif.; Northwestern University Medical School, Chicago, 1932; aged 33; died, March 12, in the Sutter Hospital, of pneumonia.

John F. White, Leoti, Kan.; Missouri Medical College, St. Louis, 1898; county coroner; aged 79; died, March 13, in the Scott City (Kan.) Hospital, of pneumonia.

Thomas W. Smith, Eutaw, Ala.; Kentucky School of Medicine, Louisville, 1894; aged 65; was found dead in bed, March 21, of a self-inflicted bullet wound.

Emily F. Swett, Medina, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1885; aged 82; died, March 27, of chronic myocarditis and arteriosclerosis.

Andrew La Roy Randall, Pleasanton, Neb.; Northwestern University Medical School, Chicago, 1903; aged 59; died suddenly, March 14, of coronary thrombosis.

Adolphe Tircuit, New Orleans; University of Louisiana Medical Department, New Orleans, 1878; aged 84; died, March 24, of sclerotic heart disease.

John C. Stevens ☉ Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; aged 72; died, March 26, of hemiplegia.

Henry Davis Rothgeb, Willow Springs, Mo.; University of Louisville (Ky.) Medical Department, 1896; aged 69; died, March 29, of cerebral hemorrhage.

Edward August Renfer, Berwyn, Ill.; Hahnemann Medical College and Hospital, Chicago, 1905; aged 55; died, April 1, of coronary thrombosis.

James Ratchford Taylor, Anniston, Ala.; Atlanta (Ga.) Medical College, 1898; aged 76; died, March 12, at the Garner Hospital, of bronchopneumonia.

Paul Thomas Logue, Fairbank, Iowa; Hahnemann Medical College and Hospital, Chicago, 1897; aged 66; died, March 9, of coronary occlusion.

William F. Walker, Colwich, Kan.; Missouri Medical College, St. Louis, 1884; aged 79; died, March 30, of acute catarrhal jaundice.

Bureau of Investigation

SLIM, CORRECOL AND HAUSER POTASSIUM BROTH

Three Concoctions Exploited by Modern Health Products, Inc., and Recommended by Benjamin Gayelord Hauser, Sold Under False and Fraudulent Claims, According to Food and Drug Administration

Three concoctions, "Slim," "Correcol" and "Hauser Potassium Broth," exploited by the Modern Health Products, Inc., of Milwaukee and recommended by Benjamin Gayelord Hauser (Bureau of Investigation, *THE JOURNAL*, April 17, 1937, p. 1359), have been declared by the Food and Drug Administration misbranded and sold under false and fraudulent claims.

Hauser Potassium Broth, "the only product of its kind recommended by Benjamin Gayelord Hauser . . ." and declared to be "the triumph of two years of scientific research by Benjamin Gayelord Hauser and associated experts . . ." by

Modern Health Products, Inc., reconciled the statement that Slim contained no drugs with the fact that it did contain laxative drugs is something that perhaps only naprapath Hauser could explain.

Correcol, the third product of the trinity seized by the federal authorities, was alleged to be misbranded in that the statement on the package "Colon Food" was false and misleading, since the article was not a food, and the package bore false and fraudulent representations regarding the product's curative or therapeutic effect. According to the Food and Drug Administration's report, Correcol consisted largely of *Lallemantia royleana* (a mucilaginous weed) and a smaller quantity of karaya gum.

Correcol was advertised by Modern Health Products, Inc., as a new wonder food from the Orient for correcting constipation and was alleged to be "a simple, natural substance producing in the intestine a soft, jelly-like mass that sweeps away delayed waste, tones the muscular action and helps re-educate the colonic function back to normal." This reeducating wonder from the Orient was also approved by "the world-famous authority on dietetics," Benjamin Gayelord Hauser.

Modern Health Products, Inc., was reported by the government to consist essentially of a mixture of ground dried plant materials, including seaweed, alfalfa leaves and stems, okra, potato starch, beet leaves and rhubarb leaves. This conglomerate mixture was sold to Hauser enthusiasts as "a blessing for those health-seekers finding it difficult to secure or prepare a regular supply of fresh vegetables. To them, Hauser Potassium Broth is little short of a miracle!"

While this concoction may have been a "miracle" to the Hauser health-seekers, the Food and Drug Administration took an entirely different view, declaring that the article was misbranded and that the package bore a false and fraudulent representation regarding the curative or therapeutic effect of the product. According to the advertising, "Potassium Broth is now almost as famous as Hauser himself. . . . Family size \$2.50."

Slim, "The English Reducing Beverage," was declared adulterated and misbranded and sold under false and fraudulent claims. Slim was alleged to be adulterated in that it contained deleterious ingredients; namely, senna, bladderwrack and buckthorn bark. This product was also recommended by "food chemist" Hauser (6-ounce can, \$1).

Slim was alleged by the government to be misbranded in that a leaflet accompanying the package carried the statement: "Slim contains no drugs and is absolutely harmless." This statement, the Food and Drug Administration held, was false and misleading, since the product consisted essentially of cathartic drugs and was not absolutely harmless. Just how

The cases involved interstate shipments of 119 packages of Slim, 95 packages of Correcol, and 146 packages of Hauser Potassium Broth. The libel praying seizure and condemnation was initiated by the United States attorney for the District of Massachusetts, based on reports by the Secretary of Agriculture. On June 8, 1936, no claimant having appeared, judgment of condemnation was entered and it was ordered that the products be destroyed.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Fahrney's Liniment.—D. Fahrney & Son, Hagerstown, Md. Composition: Essentially turpentine oil and a sulfureted fatty oil. Fraudulent therapeutic claims.—[N. J. 24060; November, 1935.]

Kohler One Night Cough Syrup.—Kohler Mfg. Co., Baltimore. Composition: Morphine sulfate and cannabis (both habit-forming drugs) and another dangerous substance, an antimony compound. Fraudulent therapeutic claims.—[N. J. 24063; November, 1935.]

Navajo Indian Herbal Teas.—Navajo Industries Co., Inc., and Paul Anacker (alias Dr. Yosemite Nabona), no address given. Composition: The "asthma tea" was essentially cut, dried herbs including elder flowers and coltsfoot; the tea for hardening of the arteries was essentially cut, dried herbs including yarrow and horsetail; the one for neurasthenia was cut, dried herbs including camomile, lavender and mint; the one for stomach catarrh was cut, dried herbs including yarrow, camomile, centaury and mint; the one for stomach trouble was essentially cut, dried herbs including camomile, elder, yarrow and mint. Fraudulent therapeutic claims.—[N. J. 24049; November, 1935.]

Old Country Dia-san.—Alfred A. Hofmann, trading as the Original Old Country Remedy Co., no address given. Composition: A coarse mixture of plant material including bearberry leaves, licorice root, peppermint leaves, buchu leaves, horsetail stems, corn silk and anise seed. For Bright's disease, rheumatism, diabetes, gout, etc. Fraudulent therapeutic claims.—[N. J. 24040; November, 1935.]

Pankoka.—Pankoka Health Foods, Inc., New York. Composition: Chocolate, sweetened and flavored. For catarrh, influenza, dyspepsia, rheumatism, diabetes, tuberculosis, etc. Fraudulent therapeutic claims.—[N. J. 24041; November, 1935.]

Nunn's Black Oil Healing Compound.—Dr. Nunn's Black Oil Co., Inc., Salt Lake City. Composition: Mineral oil and a fixed oil containing a sulfur compound. For sores, scratches, colic, piles, etc. Fraudulent therapeutic claims.—[N. J. 24046; November, 1935.]

Mild-O-Line.—John F. Class, Inc., Dayton, Ohio. Composition: Essentially mineral oil and small amounts of salicylic acid and volatile oils, including those of eucalyptus and wintergreen. Not appreciably germicidal. Fraudulent therapeutic claims.—[N. J. 24057; November, 1935.]

Browns Food Lax.—Nostane Products Corp., Brooklyn. Composition: Essentially agar agar and several species of plantago seed. For "new energy and health," constipation, headaches, etc. Fraudulent therapeutic claims. Not a food, as represented.—[N. J. 24064; November, 1935.]

Correspondence

DIET AND COMMON COLDS

To the Editor:—An editorial comment published in *THE JOURNAL*, May 15, page 1718, concerning the relation of diet to common colds, may leave the impression on many readers that unwarranted views published by me in 1928 (*Science* 68:301 [Sept. 28] 1928) were again completely abandoned by 1934 (Salt Water and Health, Chicago, a privately printed pamphlet). While it is true that the specific idea of using a high fat diet as a preventive of colds was abandoned, the basic idea that nutritional edema increased, and dehydration decreased, the susceptibility to contracting colds was by no means abandoned. In fact, the conviction was expressed in 1934 that edematous states were also the basis of other manifestations of subnormal health and to date this view has not been changed.

Another impression that the comment in *THE JOURNAL* may leave is that no confirmatory evidence concerning a relation between diet or nutritional hydration and the incidence of common colds has been published by others. It must be admitted that much more evidence has been published since 1928 to support the theory of infection as an explanation of the incidence of colds, and the possibility that infection may be a complicating factor in colds was also referred to by me in 1928 (*Proc. Soc. Exper. Biol. & Med.* 25:454 [March] 1928). However, even granting that colds are now definitely proved to be caused by infection, this does not explain the observed variations in susceptibility. That diet or nutritional hydration may explain the variability in susceptibility to colds or other respiratory infections has been pointed out by McQuarrie (*J. Nutrition* 2:46 [Sept.] 1929), Higgins (*New England J. Med.* 203:145 [July 24] 1930; abstr. *THE JOURNAL*, Sept. 13, 1930, p. 826) and Paton (*Edinburgh M. J.* 39:536 [Sept.] 1932; London Letter, *THE JOURNAL*, Oct. 29, 1932, p. 1521; *Brit. M. J.* 1:738 [April 29] 1933).

I am not responsible for the specific use of my views made by Consumer's Research. Certainly the suggestion was never made that the use of fruit juices should be restricted. Even the high fat diet described in 1928 allowed about 500 calories to be derived from carbohydrates, which were intended to

prevent ketosis. This diet was abandoned in 1934 largely because the restriction of carbohydrates to about 500 calories, together with the use of liberal amounts of fat, eventually often left the experimenter with a sense of extreme fatigue. Hence I adopted a diet containing less fat and more like the "antiretention" regimen outlined by Földes (*A New Approach to Dietetic Therapy*, Boston, Richard G. Badger, 1933). However, observations made since 1934 suggest that an entirely satisfactory dietary regimen for keeping the hydration of the organism at a low level or for preventing abnormal degrees of hydration over prolonged periods still remains to be discovered.

FREDERICK HOELZEL, Chicago.

POLYSACCHARIDE TEST FOR PNEUMOCOCCUS TYPES

To the Editor:—In a recent article by Cecil (*THE JOURNAL*, February 27, p. 689) mention is made of the use of the specific polysaccharide substance of pneumococci in determining when a patient suffering from pneumococcal pneumonia had received sufficient serum, the test being negative when inadequate serum had been given.

I have been much interested in this procedure since reading the original articles on the work by Tillett and Francis in 1929 and since, especially the report of Francis (*J. Exper. Med.* 57:617 [Aug.] 1933) and that of Abernethy (*New York State J. Med.* 36:627 [April 15] 1936). I do not find the polysaccharide antigens listed in the catalogues of any biologic houses and have been told by a salesman of one such house that in actual practice the use of the skin test with the specific soluble substance of the pneumococcus in determining the amount of serum which should be given was found impracticable and unreliable.

I should like to inquire whether this is correct and whether the procedure has been used extensively as yet. I have not heard of its being used in this vicinity. Also, where can the specific polysaccharides for the different pneumococcus types be obtained?

T. F. JUDEFIND, M.D., Loma Linda, Calif.

[This letter was referred to Dr. Cecil, who replies:]

To the Editor:—The correspondent is correct when he says that at the present time polysaccharides are not being offered to the medical public by any of the biologic manufacturers. However, the Lederle Company is planning to make it and probably by next fall these various antigens for pneumococcus skin tests will be put on the market by the Lederle Company. The test has not been used extensively as yet and I believe that it requires some experience on the part of the operator in reading the reactions accurately.

RUSSELL L. CECIL, M.D., New York.

INHERITANCE OF HEMOPHILIA

To the Editor:—As the explanation of inheritance of hemophilia in *THE JOURNAL*, May 1, page 1564, does not seem quite complete, I am offering the following comment: In man, sex is determined by the X and Y chromosomes. The male has one X and one Y chromosome and the female two X chromosomes. Hemophilia is due to a gene carried in the X chromosome and is recessive to the normal. The X chromosome of the male comes from the mother and the Y chromosome from the father. Consequently, hemophilia in the male must be transmitted by the mother. Women rarely, if ever, have the disease, although normal females may transmit the gene to their sons.

GEORGE HAINES, PH.D., Washington, D. C.
Office of Experiment Stations.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLOOD GROUPING TESTS

To the Editor:—I should like some references concerning the technic of doing the blood grouping tests when the M and N factors are concerned. These tests are to be used in conjunction with the ordinary blood grouping tests involving the A and B factors in the exclusion tests of paternity in bastardy proceedings. Are the agglutinating serums for the M and N factors manufactured and put on sale by any of the reliable drug concerns as yet?

BENJAMIN VICTOR DI IORIO, M.D., Utica, N. Y.

ANSWER.—The technic of testing for the factors M and N may be found in the original article by Karl Landsteiner and Philip Levine (*J. Exper. Med.* 47:757 [May] 1928), also, Wiener, A. S.; Zinsler, Rebecca, and Selkove, Joseph: *J. Immunol.* 27:431 [Nov.] 1934, and Wiener, A. S.: *Blood Groups and Blood Transfusion*, Springfield, Ill., C. C. Thomas, 1935, chapter 11. Any one who wishes to make the tests for M and N for applying the results in paternity proceedings must first make a thorough study of the technic in order to familiarize himself with the various pitfalls and sources of error. Even when potent serums are available, incorrect typings result in inexperienced hands. As yet, testing serums for M and N are not available commercially in this country. However, there is no question that any of the workers in the field will be glad to help any investigator who is seriously interested in the subject to get started in any studies he may wish to make.

One of the first requisites is to have available at all times persons of known types M, N and MN, whose blood can be used as controls whenever tests are made. From the reactions given by such controls one can judge the potency and specificity of the serums being used, and if the serums are found to have deteriorated they must be discarded. Moreover, since individual serums vary somewhat in potency and other properties, it is imperative in paternity cases to do the tests with at least two and preferably three reagents of each sort. This is not practicable unless the investigator prepares his own immune serums and testing fluids so that he always has an adequate supply of potent serums on hand. In addition, duplicate blood suspensions should be taken from each person and each tested separately, so as to guard against nonspecific agents, which may alter the properties of the blood suspensions.

EFFECTS OF DUST ON LUNGS

To the Editor:—What is the effect on the bronchi and lungs by concentration of dust to which one may be subject in handling corn, barley, oats and wheat? Would the irritation caused by such dust lower the local resistance of the respiratory epithelium and be a factor in causing pneumonia? Please give references to papers that will give information with regard to the industrial hazard of organic dust which occurs in grain elevators, flour mills and shoe factories. Please omit name.

M.D., Missouri.

ANSWER.—In high concentrations, no dust is entirely harmless to the respiratory tract. Compared with the action of silica, dust from barley, wheat, corn and oats is relatively insignificant. Nevertheless these vegetable dusts long have been associated with abnormal instances of pneumonia, bronchitis and emphysema. A few publications refer to a fibrotic disease attributed to flour of various types. Such a condition, however, is not well authenticated. In an earlier period, milling operations were associated with disease states to a greater extent than at present, owing to the introduction of automatic machinery, dust arresters and generally improved work conditions. In addition to slight mechanical irritation on the respiratory tract, which is reported to predispose to bacterial invasion, it is recognized that fungi mixed with grain materials may lead to fungal infection of the respiratory tissues. The latter is more commonly associated with the handling of grains than with the handling of flour itself. For a long time the term "millers' asthma" has appeared in the literature. The exact nature of this disease is not known, nor is the anemia so prevalent among bakers associated with any particular agency connected with flour or grains. It is now believed that a protein fraction of flour and other grain products may be the direct source of some pulmonary diseases among exposed per-

sons. Lately Prausnitz (Investigations on Respiratory Dust Disease in Operatives in the Cotton Industry, Special Report Series 212, Medical Research Council, London, H. M. Stationery Office, 1936) has traced certain pulmonary diseases among cotton workers to the protein fraction of the cotton.

An analogous situation exists with respect to flour and other vegetable dusts, but precise proof is lacking or incomplete. Kober and Hayhurst (*Industrial Health*, Philadelphia, P. Blakiston's Son & Co., 1924) say: "The inhalation of flour dust, in spite of the smooth and less irritating character of the individual particles comprising it, cannot fail to prove injurious to the respiratory organs. Indeed there is much reason for assuming that the lodgment of flour dust in the minute ramifications of the bronchial tubes and air vesicles, apart from clogging up the air passages and acting as an irritant, may result in collapse of a small area of the lung (atelectasis) or in a dilatation of the vesicles and an abnormal collection of air in the lung tissue, technically called emphysema and popularly known as 'millers' asthma.' Other diseases of the lungs are even more common. According to Hirt, 20.3 per cent of all the diseases affecting millers are pneumonia, 9.3 per cent bronchial catarrh, 10.9 per cent consumption and 1.9 per cent emphysema, a total of 42.4 per cent from diseases of the respiratory passages."

According to the Encyclopedia of Occupation and Health (International Labor Office, Geneva, 1930) "L. Ferrannini studied in 1912 the action of flour inhaled by millers. Although flour is generally considered to be innocuous to the respiratory tract, nevertheless there are writers, especially in past times, who have considered it to be the cause of bronchopulmonary troubles. Thus, for example, Ramazzini speaks of cough, asthma and anemia which he found among millers; Hirt, of respiratory affections; Ascher, of bronchopulmonary lesions; Seiffert, of nasal and pharyngeal lesions; Schuster, of the frequency of pulmonary tuberculosis; Muller, of lesions analogous to those due to pneumoconioses."

The figures quoted are regarded as somewhat old and scarcely applicable at the present time. In addition to the publications mentioned, some material dealing with the situation may be found in "Industrial Dusts," by Drinker and Hatch (New York, McGraw-Hill Book Company).

DIAGNOSIS OF GONORRHEA

To the Editor:—I am writing to inquire whether an absolute diagnosis of gonorrhea can be made with Loeffler's methylene blue stain. I have been told that it can be differentiated only by culture. I have noted on two routine smears taken of patients in the hospital that they showed both intracellular and extracellular diplococci in groups in virgins without symptoms. What other organism may produce an acute urethritis resembling gonorrhea in all its characteristics? I have now a young married couple both of whom show symptoms resembling gonorrhea. Smears show intracellular and extracellular diplococci yet both state that there has been no previous venereal history and both deny clandestine intercourse. They have a child 2 years old. It is my opinion that this is a nonspecific condition perhaps from an endocervicitis following the trauma of delivery. Please omit name and address. M.D., Ohio.

ANSWER.—An absolute diagnosis of gonorrhea cannot be made with Loeffler's methylene blue stain or even with the much more valuable Gram stain. The methylene blue stain reveals only the size and morphology of the intracellular and extracellular cocci. *Neisseria intracellularis* (meningococcus), *Neisseria catarrhalis*, *Neisseria sicca* and *Neisseria flava* may closely resemble one another in smears. They are all gram negative. There are also a number of gram-positive cocci which have a similar appearance but do not concern us here.

For the usual examination of smears for gonococci the Gram stain should be used. In urethral smears gram-negative diplococci, coffee bean shaped, may be considered positive for gonococci whether intracellular or extracellular. In smears from the cervix and the vagina only the typical intracellular organisms are to be considered positive unless confirmed by culture and special tests, since other micrococci are often present.

The tests of greatest value are cultures on appropriate mediums, reactions on carbohydrate mediums, the alkali solubility test and the gonophage test.

In a Gram stain of exudate from acute cases gonococci appear in small clusters in the pus cells, and there is often a clear zone around the cocci. In chronic cases the organisms tend to disappear from the mucous surfaces and to localize in the small mucous glands. They are soluble in alkali and hence tend to disintegrate in alkaline mucus. From a Gram stain one should report the presence or absence of gram-negative intracellular or extracellular diplococci. The presence of gonococci should not be reported unless confirmed by culture and special tests. This is important in medicolegal cases.

The culture mediums often used are ascitic glucose agar, ascitic fluid agar, Gradwohl special ascitic fluid hormone brom-cresol purple agar, and calf brain veal broth agar. Growth is more abundant in an atmosphere containing an increased amount of carbon dioxide (about 10 per cent).

The alkali solubility test is performed as follows: Wash the pure culture with physiologic solution of sodium chloride. In a small test tube place equal parts of suspension and tenth-normal sodium hydroxide solution and shake well. Gonococci dissolve quickly and the fluid becomes clear. Other confusing bacteria do not dissolve. The meningococcus is partly dissolved but leaves a slight opalescence.

Characteristics of *Neisseria*

	Growth on Plain Agar	Growth at 22 C.	Fermentation with Acid Formation			
			Dextrose	Maltose	Levulose	Sucrose
<i>Neisseria gonorrhoeae</i>	—	—	A	—	—	—
<i>Neisseria intracellularis</i> ...	—	—	A	A	—	—
<i>Neisseria catarrhalis</i>	+	+	—	—	—	—
<i>Neisseria sicca</i>	+	+	A	A	A	A
<i>Neisseria flava</i>	—	—	A	A	A	—

Old cultures that have become autolyzed contain a bacteriophage that is specific. This causes lysis of the organism after five hours or more.

From time to time cases of nonspecific purulent urethritis are seen in the male. It is this type which requires a culture diagnosis. The forensic physician must be sure of his ground, as gram-negative diplococci in the male or female are not necessarily gonococci. Some cases of vaginitis in children are due to gram-negative streptococci instead of gonococci. In any doubtful case the patient should be taken to a competent bacteriologist for cultural studies.

The accompanying table presents the important characteristics of the various species of *Neisseria*.

SENSITIVITY TO FEATHERS AND DUST

To the Editor:—I have an asthmatic patient who suffers somewhat the whole year but to a greater degree from September to January. She reacted only to feathers and dust in about 300 tests. She has taken vaccine for feathers and dust for two years. She took a trip to New York weeks ago and felt fine, with no asthma, and the next day after returning home had an attack, which has been almost continuous since. What would you suggest? What kind of heat in the home would be best? The family has low pressure steam. Are the air conditioned attachments for a steam job satisfactory? Is filtered hot air heat better?

JOHN M. PRESSLY, M.D., Belmont, N. C.

ANSWER.—It would seem obvious that dust and feathers exist in New York as well as in North Carolina and that they might be identical in the two places. However, the patient may have in her home some dust peculiar to her environment, as dust from pet animals, ozite floor pads, clothing, foods or automobile equipment. The variety and origin of the allergens is almost limitless. There is a quotation that has been used by many medical commentators to the effect that, if a patient has symptoms in one town and not in another, the basic cause of the trouble lies not in the patient but in the city where the trouble occurred. There is a certain nervous imbalance in every person with allergic reactions. This should always be kept in mind. It may be that in the case cited the nervous imbalance occasioned by the environment is more important in the production of the asthma than is the sensitiveness to feathers and dust. To date there is nothing better in identifying an air-borne allergen than skin sensitization tests. Nevertheless, the results of the reactions must not be accepted as absolute proof with regard to the etiology of the allergic symptoms. Skin sensitization tests leave much to be desired. There is one way to prove clinically which factor is to blame for a systemic allergic reaction. One should start when the patient is symptom free and then bring the patient in contact with one article of food or material at a time. Detailed notes should be kept as to the patient's reactions. Such sleuthing requires infinite patience and time. The patient can do this unaided. Naturally, well humidified heat is the best, and any air conditioning attachment for steam heated buildings is at the present time unsatisfactory. Properly filtered hot air will be the most efficient form of heat, but at the present time, in spite of all advertising to the contrary, air conditioning of buildings is far from perfect, although tremendous advances are rapidly being made by commercial companies.

FORCEPS DELIVERY AND SQUINT

To the Editor:—A baby delivered by a moderately forceful forceps extraction was noted by the parents to have a "mark" at the lateral angle of the eyelid margins, which was assumed to be due to forceps pressure. This small pressure scar was called to the attention of the doctor twice within the year following delivery and was accepted as evidence of forceps pressure with some reservations. The baby developed normally and only an occasional squint was noted until at the age of about 1 year and 9 months the child was taken on a several thousand mile intensive automobile trip of three or four weeks' duration. Distances of 400 to 600 miles a day were driven. The child lost weight and was definitely fatigued by the trip. Immediately after this trip a premonitory convergent squint developed, which soon became a permanent monocular convergent squint involving the eye near the scar described. At operation about a year later there was declared to have been found quite a palsy of the lateral rectus muscle, and the question arose as to whether the squint was paralytic in type and secondary to forceps injury. The child, now 6 years of age, has had to wear fairly strong hyperopic and astigmatic corrective lenses. Of course, as described, this a typical case of concomitant squint; however, could forceps pressure have been a prime factor in the development of this delayed muscular palsy? How frequently is forceps injury assumed to be related to squint? Please omit name.

M.D., Salinas, Calif.

ANSWER.—The history is characteristic of a typical concomitant squint and it is highly improbable that the forceps delivery was related to the condition that developed twenty-one months later. As far as is known, there are no statistics showing any relationship between forceps delivery and the later development of a nonparalytic squint. The presence of the high hyperopia and the excessive fatigue of the automobile trip were probably sufficient to break the fine muscle balance that had held the eyes parallel up to that time, after which the usual course of such a squint was followed.

ARTIFICIAL FEVER TREATMENT OF NEUROSYPHILIS

To the Editor:—I have a patient with neurosyphilis and sent him over to a doctor in Omaha for heat treatment. The treatment is very hard on him and he is skeptical. He insists that I write you to know if this is the best treatment and if not what is. He is taking mapharsen and a bismuth compound at the same time. If you can give me any information on this treatment I would appreciate it. Please omit name.

M.D., Iowa.

ANSWER.—It is difficult to give an intelligent answer to this inquiry because of the meager data given. Neither is the treatment of neurosyphilis as simple as the inquiry would infer. The treatment of neurosyphilis varies greatly with the type of neurosyphilis manifested, the stage of the disease, and the age and the general condition of the patient. Experience has shown that routine treatment will materially help several of the different forms of the disease, while in the other resistant types fever therapy will often be of benefit; a certain few will continue to progress in spite of any therapeutic efforts. Fever treatment by either the electrical fever producing units or by malaria is difficult for the patient to endure, but the results usually warrant the patient's undergoing the ordeal, especially if his infection has shown a tendency to be resistant to routine treatment. From this brief inquiry it would appear advisable to urge the patient to follow out the regimen suggested by the Omaha physician, as it apparently offers the patient the best means of controlling the disease.

POSTERIOR DISLOCATIONS OF HIP

To the Editor:—Will you please send me information with reference to the incidence of posterior dislocations of the hip and the coincidence of posterior dislocation of the hip occurring in more than one patient involved in the same accident. If you have literature available discussing these topics, I would be pleased to have references. Please omit name.

M.D., New Jersey.

ANSWER.—Posterior dislocations of the hips are more frequent than any others in which that joint is involved, occurring about seven times as often as anterior dislocations. However, traumatic dislocations of the hip joint of any type are relatively infrequent. Until the last few years, when highway accidents have become more and more common, the incidence was given at about 2 per cent of all dislocations. While there are no entirely reliable statistics, the incidence of traumatic dislocations of the hip as compared with all dislocations is today nearer 5 per cent. No report has been found in which there was a description of this injury in more than one patient involved in the same accident.

Textbook discussions of traumatic posterior dislocation of the hip may be found in:

Key, J. A., and Conwell, H. E.: *The Management of Fractures, Dislocations and Sprains*, St. Louis, C. V. Mosby Company, 1934.
Speed, Kellogg: *Fractures and Dislocations*, Philadelphia, Lea & Febiger, 1928.

PAROXYSMAL LABYRINTHINE VERTIGO

To the Editor.—A married man, aged 38, has sudden attacks of violent retching, vomiting, nausea and vertigo of such severity that it is necessary for him to be led to a resting place. The attacks last three hours, after which time he recovers completely and is perfectly well until about six weeks later, when the same phenomenon is repeated. Physical examination, the blood Wassermann reaction, urine examination, blood pressure and the blood count are all entirely negative. The history is of no special importance except that there was a football injury to the back of the head twelve years previously. There was no fracture, but a slight concussion. Could you kindly help me in the diagnosis and treatment of this condition. Please omit name.

M.D., Pennsylvania.

ANSWER.—This man has paroxysmal labyrinthine vertigo. He should be examined in detail by a competent neurologist and otologist to determine the presence of organic disease of the brain, especially the auditory nerve, the vestibular nerve and the temporal lobe. One should look for cerebellopontile angle signs and symptoms. If no evidence of a neoplasm is found in these regions the following regimen is suggested: large doses of ammonium chloride, 1 Gm. three or four times daily with diminution of the salt intake. If after a trial of six months with this medication the paroxysms persist, one may consider the possibility of cutting the vestibular nerve intracranially. This nerve is cut on the side of the tinnitus aurium. If a neoplasm is found, neurosurgery is indicated.

TUBERCULOUS EPIDIDYMITIS

To the Editor.—A patient, aged 35, has had the left epididymis removed for tuberculous epididymitis, proved by smear and histologic study. The wound is healed. Repeated examinations of the urinary sediment reveal no pus or tubercle bacilli. The prostate, by rectum, is of normal size, and the expressed secretion contains a large amount of pus. This specimen showed no tubercle bacilli on stained smear. Neither seminal vesical is palpable. The patient is receiving heliotherapy. Should the opposite vas be divided and tied to prevent the epididymis on this side from becoming infected?

M.D., San Diego, Calif.

ANSWER.—As tubercle bacilli have not been demonstrated in expressed smears from prostate and vesicles, there is no evidence to prove that this organism is the cause of the infection at the bladder neck. Some, if not many, of the epididymal infections are hematogenous in origin, and tying off the vas would not necessarily prevent tuberculosis of the remaining epididymis.

DISCOLORATIONS OF SKIN

To the Editor.—Would you kindly tell me the best means of removing discolorations from the skin following injection of superficial varicosities. I have a patient whom I have treated for disfiguring varicosities of the skin. This has been followed by a brown pigment, which fades very slowly. I should like to know whether there is any way of hastening the removal of this discoloration.

J. B. KINNE, M.D., Aberdeen, Wash.

ANSWER.—An exact description of the method and substance employed for thrombosing the varicosities has not been furnished by the correspondent. Since it has been stated that the "brown pigment fades very slowly," it would seem that what were described as discolorations were probably hemorrhagic extravasations into the surrounding tissues and that the discoloration as described was caused by the deposit of blood pigments hemosiderin and hematin.

The normal absorption of the pigment will undoubtedly take its regular course in due time. As in the treatment of hematomas localized to other regions, hot fomentations and other forms of local heat applications may prove of some value in hastening the process.

PERSISTENT CHILLS OR EPILEPSY

To the Editor.—A man, aged 58, has been ailing for the past fifteen years with chills. There is no elevation of temperature accompanying these chills, which last for a period of one hour or more. I have tried various medicaments with little relief. The chills come on at any time of the day without regard to the weather. The patient at the present time is being treated by me for a duodenal ulcer. Is there any connection between these ailments? Please omit name.

M.D., Illinois.

ANSWER.—It is not probable that a patient should have chills over a period of fifteen years without accompanying fever or sweating. If the patient has not been under close or continuous observation, it is sometimes difficult to determine whether the patient has had a rigor or an epileptiform or a hysterical attack. The diagnosis of epilepsy is rendered easy if the patient loses consciousness during the shivering or if he gives a history of similar attacks on previous occasions. Epileptic attacks may be difficult to differentiate from rigors that are hysterical in origin. If the attack should be of the latter variety, the patient's face would be red, not livid and

shrunk, as in the case of a true chill. The temperature would not be elevated, and there should be a history of previous hysterical manifestations.

There do not seem to be any recorded instances of the association of chills with duodenal ulcer.

BLEEDING AFTER COITUS

To the Editor.—A man, aged 40, has been complaining for the past five months of the passage of a considerable amount of blood immediately following intercourse. There is no bloody discharge at any other time and no history of gonorrhea or syphilis. Treatment to date has consisted in massage of the seminal vesicles, instillation of 0.5 per cent silver nitrate into the prostatic urethra and some restriction of the frequency of coitus. None of these measures have benefited the patient any. I should like to have any suggestions you might have to offer as to diagnosis, treatment and prognosis. Please omit name.

M.D., Pennsylvania.

ANSWER.—In all probability this patient suffers from either a chronic prostatitis or a chronic seminal vesiculitis or both. The patient, of course, should be examined with the cystoscope to rule out the possibility of stone, tumor or other lesions in the bladder that might cause bleeding. The prognosis is favorable. With regard to treatment, massage of the prostate and seminal vesicles at weekly intervals is indicated. Instillations of silver nitrate had best be omitted. The restriction of the frequency of coitus is a correct procedure. Internally it might be well to give the patient 0.65 Gm. of potassium iodide three times a day with a glass of water, after meals.

PANCREATIC CALCULI

To the Editor.—A man, aged 56, an automobile mechanic, had severe cramplike pains over the epigastrium for three weeks, sharpest three hours after meals, and over the left costal margin. He then passed a cupful of calculi and the pain ceased. The stones were of calcium, phosphate and carbonate. No bile coloring matter was found. They were up to half an inch in diameter. Can these stones be pancreatic in origin? The treatment seems to be surgical or dietetic. The dietetic treatment seems to aim to reduce pancreatic secretion. As the cause of these stones is given as obstruction or decreased secretion, should not this diet be such as to increase pancreatic secretion? Please omit name.

M.D., California.

ANSWER.—The stones as described correspond in composition to pancreatic calculi. To prevent their formation, increasing the flow of pancreatic juice is indicated. This may best be accomplished by frequent feedings (six meal plan) and the drinking of an abundance of water. If there is hypochlorhydria, the administration with meals of diluted hydrochloric acid may be indicated. Pilocarpine nitrate has also been given with the intention of increasing the flow of pancreatic juice. The dosage (0.005 Gm. more or less) would, of course, have to be kept below the point of making the patient uncomfortable by salivation, diaphoresis or nausea.

SIGNS OF PULMONARY EMBOLISM SEEN IN AUTOPSY

To the Editor.—How often after death from pulmonary embolus will evidence of the embolus and its resultant effects be found in the lung at autopsy done within twenty-four hours of the time of death? Is it possible to have sudden death from pulmonary embolus and not find at autopsy within twenty-four hours any evidence in the lung?

WILLIAM B. SMITH, M.D., Wethersfield, Conn.

ANSWER.—It is not conceivable that sudden death from pulmonary embolism can take place without detectable evidence of its occurrence at necropsy within twenty-four hours of death. In cases of massive embolism of the pulmonary artery and its large branches, the changes in the lung tissue itself may not be marked, but there would be present in the arteries the embolus itself.

SENILE CATARACT

To the Editor.—Please advise me whether there is a calcium deposit in cataracts and if a milk or cheese diet is detrimental.

CARLETON DEEDERER, M.D., Miami, Fla.

ANSWER.—Calcium is one of the constituents of the ash of the normal lens. Its amount is exceedingly small but is considerably increased in senile cataract (Collins and Mayou: Pathology of the Eye, p. 624). If simple senile cataract is the type in question, it may be stated that there are no free calcium deposits in the lens but that the calcium is in solution in the tissues. Deposits of calcium in the form of plaques occur only in later degenerative forms. There is no reason to believe that a milk or cheese diet would be detrimental in the case of senile cataract.

LEAD POISONING IN CHILDREN

To the Editor:—I have a patient, a baby girl, who shows signs of lead poisoning. I have examined everything thoroughly that has been used in the preparation of her food and in the course of the investigation the rubber nipples were examined. I took roentgenograms of these nipples together with samples of several different kinds from the drug store and found that three or four cast heavy shadows but that the particular one used for this child cast the heaviest shadow. I am wondering whether you could give me any information regarding the use of lead in the making of nipples and also whether or not this could be considered as the cause of lead poisoning.

A. L. ARNOLD JR., M.D., Owosso, Mich.

ANSWER.—Lead poisoning in children may be caused by ingestion of lead from various sources. Among the more common sources of lead poisoning are the enamel from cribs, painted furniture and toys with which the infant comes in contact. Licking painted walls is another source of lead poisoning.

While sulfur and other chemical elements are employed in the processing of rubber, lead is usually employed only in the rubber gloves and aprons that are used as protection in x-ray work. The rubber nipples mentioned in the query might be sent to a chemist and tested for lead, or the manufacturers might be interrogated as to the use of lead molds or any lead employed in the processing of the nipples.

Perhaps another careful history would reveal a source other than the rubber nipples from which the baby might have contracted the lead poisoning.

PSYCHOSIS IN IDENTICAL TWINS

To the Editor:—In a hospital at the present time are identical twin sisters, aged 27, one single and one married, showing a general manic type of psychosis, with schizophrenic coloring in the single sister. I am interested in knowing the incidence of psychosis in identical twins. I would appreciate it very much if you could give me the statistics on this or tell me where I might be able to find them. The married sister had the first attack a year ago. The married sister entered the hospital two months following the entry of the single sister and with a complication of bronchopneumonia.

J. W. DOUGHTY, M.D., Sedro-Woolley, Wash.

ANSWER.—There is some evidence that, on the whole, mental disorders are somewhat more common among twins, especially monozygotic, than among singly born persons; but it is not likely that manic-depressive psychoses, in particular, are more common among them. Not many studies of mental disorders in twins have been made, although it was pointed out in the seventies of the last century, by Francis Galton, that researchers on twins should shed much light on the hereditary factors in human temperament and in the etiology of constitutional mental disorders. A discussion of this matter, together with a selected list of references, is given by Rosanoff, A. J.; Handy, L. M., and Plesset, I. R.: *The Etiology of Manic-Depressive Syndromes with Special Reference to Their Occurrence in Twins*, *Am. J. Psychiat.* 91:725 [Jan.] 1935.

LEAD TREATMENT IN CANCER

To the Editor:—I was told a few days ago that in cases of inoperable malignant growths, especially the sarcomas, there is a method of treatment by means of lead poisoning. The physician who was telling me this was not certain of the details but said he had read an article recently. As I have a patient with inoperable fibrosarcoma, who is suffering a fair amount of pain, and as I do not remember reading anywhere of any such treatment as giving lead by injection beyond the point of tolerance and then treating for the ensuing plumbism, all this with the view of ameliorating and causing regression of the malignant growth, would you please enlighten my ignorance. Please omit name. M.D., New York.

ANSWER.—The use of lead preparations in the treatment of cancer has been generally abandoned. The administration of lead selenide was advocated some years ago as a less toxic product. These agents have not proved their value in the treatment of cancer and should not be generally employed. In view of their toxicity, their use is justified only on an experimental basis in the large clinics where the investigation can be carefully controlled. Even under these conditions their use is questionable.

CHRONIC PROSTATITIS

To the Editor:—I have a case of nonvenereal chronic prostatitis showing little or no hypertrophy at present, clinically free from symptoms except for pus cells in the secretion following massage. What should I advise the patient as to moderate sexual intercourse? What danger of infection is there to the woman? Please omit name. M.D., Massachusetts.

ANSWER.—If it has been proved that the gonococcus is not present in the pus obtained from the prostate, there is no danger of infection to the woman.

Sexual intercourse sometimes has a tendency to stir up these cases.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 12, page 2066.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*, June 21-23 and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held in different centers of the United States and Canada in October. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OPHTHALMOLOGY: *Chicago*, Oct. 9. *All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF SURGERY: *Part I (written)*, Sept. 20. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

Book Notices

Safe Childbirth: The Three Essentials. 1. Round Brim. 2. Flexible Joints. 3. Natural Posture. By Kathleen Olga Vaughan, M.B. With foreword by Howard A. Kelly, M.D., LL.D. Cloth. Price, \$3. Pp. 154, with 49 illustrations. Baltimore: William Wood & Company, 1937.

The author's object in writing this book was to simplify the attendance on childbirth while making it a safer and easier process for both mother and child. She made a thorough study of the processes of labor among civilized, semicivilized and uncivilized people in many parts of the world. This investigation led her "to the conclusion that the essential factors which make for the safety of mother and child in every birth are the round pelvis, mobile pelvic joints, and the use of the natural posture for delivery. . . . These are all characteristic of the healthy woman to whatever race she belongs. . . . Difficult childbirth is not a matter of chance nor is it dependent on the will of Heaven, but it follows the violation of the fundamental laws of health." The author shows that the evils associated with childbirth which exist in civilized countries are due to improper training of girls in childhood, to the lack of sufficient sunshine, fresh air and proper exercise, to improper food and clothing, to bad habits during pregnancy and postural errors which prevent the necessary expansion of the birth canal during labor. The author maintains that a vegetarian diet is the natural one for pregnant women. She describes and illustrates exercises for pregnant women and the correct posture which should be assumed by women in the different stages of labor. She emphasizes that parturition and defecation are similar processes. The same muscles are used in the two, but in one the *vis a tergo* is the uterine muscle, in the other the intrinsic muscles of the intestine. In both cases they are aided by the abdominal muscles and by posture. The author feels confident that, if we would only adopt the natural posture during the birth of children, most of our troubles would disappear. Puerperal sepsis would soon be a thing of the past. Adopting the natural position during labor is, however, no cure for the oval pelvis and for stiff joints. The blame for these lies on the shoulders of those who brought the patient up, her mother above all, then her school. The two habits of civilization which destroy the natural shape of the pelvis are neglect of the squatting position for defecation and the wearing of high heels. For those interested in improving obstetrics this book will prove fascinating. It is well written and has many interesting illustrations.

Die Diät- und Insulinbehandlung der Zuckerkrankheit für Studierende und Ärzte. Von Dr. Franz Depisch. Mit einem Vorwort von Prof. Dr. N. v. Jagl. Paper. Price, 4.80 marks. Pp. 136, with 8 illustrations. Vienna: Julius Springer, 1937.

For the reader of German who wishes a brief yet thoroughly satisfactory treatise on diabetic therapy, this little book will afford great satisfaction. It is practical and based on the following consideration of underlying theory:

Diabetes is considered to be a condition in which the normal balance between the excretion of sugar by the liver and its utilization in the periphery is disturbed so that the former process predominates, sugar thereby rising in the blood and

overflowing into the urine. The maladjustment between supply and utilization of blood sugar depends on disequilibrium between the activity of the insular mechanism and that of the regulators of blood sugar opposed to the insular mechanism. Such counterregulation is effected by the secretions of the adrenal and other glands as well as by the sympathetic nervous system. Certainly in the large majority of cases of diabetes and possibly in all cases the disturbance is primarily one of functional insufficiency of the islands; nevertheless the possibility exists of diabetes attributable exclusively to hyperactivity of the counterregulatory mechanism. Pure insulin insufficiency and pure hyperactivity of counterregulation represent extremes between which may be found all degrees of combination of the two. Insufficiency of insulin is not alone responsible in the average case of diabetes; the condition is influenced invariably by the state of the counterregulatory mechanism.

Treatment is adjusted accordingly. For cases in which insulin insufficiency predominates, preservative therapy is instituted. This is accomplished either by administering insulin or by limiting the intake of sugar formers (carbohydrate, protein), with dependence on fat to supply calories. Such a regimen has the disadvantage of being stimulating to the counterregulatory mechanism, but usually this is outweighed by the resulting increased efficiency of the insular mechanism; the disadvantage furthermore is overcome by gradual additions of carbohydrate to the diet after the urine has become sugar free. For cases in which hyperactivity of the counterregulatory mechanism predominates, more carbohydrate is given and the fat of the diet is simultaneously restricted. Illustrative cases are cited and dietary details are provided.

It commonly has been supposed that complete failure of the island mechanism is responsible for diabetic coma, but against such a view is the fact that the pancreas obtained from a patient dying in coma is found to contain appreciable amounts of insulin. It also is frequently observed that the doses of insulin necessary to overcome coma are many times those required for the control of the severest cases of diabetes not complicated by coma. The author is therefore led to the conclusion that intense overactivity of insulin antagonists must be largely responsible for the development of coma. This explanation not only accords with the facts opposed to the older supposition but harmonizes with the beneficial therapeutic effect in coma of fructose and dextrose, which exert a dampening effect on the activity of the counterregulators. The author suggests that benefit might be effected by paralyzing the innervation of the liver by means of paravertebral anesthesia. These theoretical considerations receive more complete discussion elsewhere (Depisch, Franz: Ueber die Theorie und Praxis der Behandlung des Diabetes, *Ergebn. d. inn. Med. u. Kinderh.* 48:1, 1935).

Maternity and Post-Operative Exercises in Diagrams and Words. By Margaret Morris, C.S.M.M.G. In collaboration with M. Randell, S.R.N., S.C.M., T.M.M.G. (Twenty-One Exercises). Introduction to Maternity Exercises by Professor R. W. Johnstone, C.B.E., M.D., F.R.C.S.E. Introduction to Post-Operative Exercises by Professor John Fraser, M.C., M.D., F.R.C.S.E. Cloth. Price, \$2. Pp. 152, with illustrations. New York: Oxford University Press, 1936.

In this book Margaret Morris illustrates and describes a series of twenty-one exercises for pregnant and puerperal women and women who have been operated on. Special attention is given to training in deep breathing and relaxation to establishing good posture. Prof. R. W. Johnstone observed the teaching of these exercises for a year at the Edinburgh Royal Maternity Hospital and he is of the opinion that the results are distinctly encouraging. Prof. John Fraser, who wrote the introduction to the section on postoperative exercises, is satisfied with the soundness of Miss Morris's scheme and believes that their application will yield most beneficial results. The author emphasizes that the book is intended primarily for masseuses, midwives and nurses who have taken the "maternity and post-operative exercise diploma" of the International Institute of Margaret Morris Movement and for students doing the two or three years' "teaching" or "remedial" training. The Margaret Morris movement is a method of physical and mental training that has evolved over a period of twenty-six years. There are now four main divisions of it, normal, medical, athletic and esthetic, but all are interrelated. The author also points out that it is not advisable to try to learn the exercises

which she illustrates and describes solely from the book. She cautions that the exercises should be carried out under medical supervision. The author is to be commended for the excellence of her drawings and the clarity of her descriptions. Nevertheless, as she herself says, one must take a prolonged course under her or one of her disciples in order to obtain the full benefits of the exercises described in the book.

Études neurologiques. Les myoclonies vélo-pharyngo-laryngo-oculo-diaphragmatiques—La maladie de Friedreich—Pathologie du névraxe. Par Georges Guillaumin, professeur de clinique des maladies du système nerveux à la Faculté de médecine de Paris, et Pierre Mollaret, médecin des hôpitaux de Paris. Seventh series. Paper. Price, 60 francs. Pp. 302, with 78 illustrations. Paris: Masson & Cie, 1936.

This book is the seventh of a series written by Georges Guillaumin on neurologic studies. In this edition Pierre Mollaret is co-author. All the material publication was studied and analyzed in the clinic at the Salpêtrière. It is divided into three parts: myoclonus of the palate, pharynx, larynx, eyeballs and diaphragm; Friedreich's ataxia; pathology of the cerebrospinal axis. Myoclonus of the palate and pharynx is discussed in detail with all the available literature to date. Not only are the clinical aspects given but the pathologic appearances are dealt with at considerable length. The authors feel the essential lesion to be briefly that concerning the dentate nucleus, the bulbar olive, posterior longitudinal bundle, superior cerebellar peduncle and the red nucleus. They have attempted rather successfully to place this syndrome in an orderly nosology, semeiology, pathology and physiology. The second part, dealing with Friedreich's ataxia, draws attention to a cardiac bulbar syndrome with alterations in the electrocardiogram as well as labyrinthine difficulties. All subgroups of the cerebellar degenerative syndromes are adequately discussed. The third part includes original studies on Pick's disease, pinealomas, infectious diseases of the central nervous system, torsion spasms and indications for cisternal and lumbar punctures. There is an excellent bibliography after each chapter. This book, like all the previous series, is highly recommended to all neurologists.

Childless: A Study of Sterility, Its Causes and Treatment. By Sam Gordon Berkov, M.D. Cloth. Price, \$3. Pp. 307, with 9 illustrations. New York: Lee Furman, Inc., 1937.

This book will prove fascinating to the public for whom it was written, because it is easy to read and it contains a great deal of interesting information. However, little space is devoted to the actual causes and treatment of sterility, for the book is really a historical and philosophic treatise on the subject of sterility. It is divided into three parts, the first of which contains a discussion of our sterile civilization, social aspects, the second how we reproduce ourselves, biologic aspects, and the third the conquest of sterility. The last part occupies only thirty-one pages. Even in these only a small proportion is taken up with the actual discussion of the treatment of infertility. The author does not think much of artificial insemination and he particularly discourages the use of donor's semen for this purpose. He likewise and properly lacks enthusiasm for plastic operations on the tubes to overcome sterility. At the end of the book is an extensive list of references which even physicians will find useful.

Die Fermente und ihre Wirkungen. Von Prof. Carl Oppenheimer, Dr. phil. et med. Supplement. Lieferung 3 (Bd. I: Spezieller Teil: Hauptteil 8, 9). Paper. Price, \$6.80. Pp. 321-480. The Hague: W. Junk, 1936.

Die Fermente und ihre Wirkungen. Von Prof. Carl Oppenheimer, Dr. phil. et med. Supplement. Lieferung 4 (Bd. I: Spezieller Teil: Hauptteil 9-12). Paper. Price, \$6.80. Pp. 481-640, with illustrations. The Hague: W. Junk, 1936.

The continued compilation and abstracting of the rapidly accumulating literature on enzymes and their actions as presented by Oppenheimer in these supplements to volumes 1 and 2 of his monumental work *Die Fermente*, edition 5 (1935), should be welcomed by all workers in the field of enzymes. The last two supplements under consideration here cover heteroxidases in general and more specifically those acting on cardiac, uronic acid, and mustard oil glucosides. Polyase action is discussed in detail in conjunction with the modern conception of the structure of the polysaccharides. The preparation, characteristics and differential actions of the different types of amylases

are presented fully, with briefer treatment on fructase, inulase, cytases, pectinases and cellulases. Under nucleases the controversial situation on the types of phosphatases necessary for the liberation of phosphoric acid from the plant and animal nucleic acids is presented. The more modern views on the mechanism of deamination of amino acids and free and combined purines are properly emphasized. The complex problem of arginase activation is covered thoroughly. In connection with muscle chemistry, the new views on the possible action of a phosphaminase on creatine phosphate are timely. Urease is reviewed thoroughly. The proteases are treated only in part in supplement 4, being limited to the general discussion of the theoretical aspects of the possibility of specific unions other than peptide linkings between units in the protein molecules. The detailed discussions on pepsin, trypsin and erepsin will no doubt appear in later supplements. The terminology adopted by Oppenheimer appears rather unfortunate in part. This holds in particular for the old terms pepsin, trypsin and erepsin, which he refers to as pepsinase, tryptase and ereptase. The work is not only an excellent review on the enzymes proper but equally valuable on the structures of the polysaccharides and proteins and the products obtained from them at various stages of hydrolysis.

Nouveau traité de psychologie. Par Georges Dumas [editor], professeur à la Sorbonne. Tome V, Fascicule 1: *La perception.* Par B. Bourdon, professeur honoraire à l'Université de Rennes. Paper. Price, 15 francs. Pp. 84, with 37 illustrations. Fascicule 2: *Les opérations intellectuelles.* Par H. Delacroix, doyen de la Faculté des lettres de l'Université de Paris. Paper. Price, 20 francs. Pp. 85-184. Fascicule 3: *La croyance. La psychologie de la raison: Nature et fonction de l'intelligence.* Par H. Delacroix, doyen de la Faculté des lettres de l'Université de Paris. Paper. Price, 20 francs. Pp. 185-304. Fascicule 4: *Le temps et les souvenirs. Le rêve et la rêverie.* Par H. Delacroix, doyen de la Faculté des lettres de l'Université de Paris. Paper. Price, 20 francs. Pp. 305-404. Paris: Librairie Félix Alcan, 1936.

These four pamphlets form the fifth volume of the rather massive treatise on psychology edited by George Dumas, who is one of the leading psychologists of France. The various authors also are authorities in their particular field, and the whole atmosphere of Dumas' complete study is one of scholarliness and careful summarization of known theoretical material. The first part of the volume deals with perception, and in general one can say that the point of view is quite modern but not, of course, clinical. Much more space is devoted here to the gestalt interpretation of perceptual ability than in any previous work of a similar nature. Perception is summarized from the standpoint of ability to assimilate various sensations and bring them together in a relationship. Much of the older material on the subject is retained, although a good deal of earlier experimental work and perception, which has been quoted extensively in American works, has been neglected. Much space has been devoted to illusions, as has been the custom, and this might well be justified, for in the study of illusions one does gain much understanding of the way in which sensory impulses are fused and integrated.

The part of this volume devoted to intellectual operations is again quite theoretical. It deals largely with such concepts as those of number and of language, the various laws of language, how expressions are phrased, and how intercommunication between individuals in the formation of various concepts are brought about. This section is probably more rational and philosophic than any other part of the volume.

In the third section, devoted to belief and the psychology of reason, one finds a good summary of our modern understanding of intelligence. There is a historical introduction and various points of view are taken up. Such factors as intelligence as a special trait and as a general factor running through the whole mind are carefully discussed. In addition, suggestibility, belief and knowledge, organization and structure of thought, and similar mental traits and capacities are discussed from the standpoint of the teaching psychologist. There is also included some explanation of intelligence as manifested by animals, but it is far inferior to the animal psychology that is now so much stressed in the United States.

The last part of the volume, devoted to time, memory and dreaming, again is a conglomeration of theory with a little practice. Much stress is laid on the interpretation of an individual's understanding of time and the theoretical concep-

of memory. The memory concept as discussed here is somewhat of an improvement on that of the early experimental psychologists, but it does not integrate modern American psychologic studies of mnemonics with the gestalt theory and animal experimentation, which offers some good explanations of memory and allied phenomena. In this part, however, are the two sections of most interest to the psychiatrist and practicing physician, a few pages devoted to amnesia and paramnesia, and there is also a section devoted to the interpretation of dreams. Both of these are much shorter than those currently found in psychoanalytic and psychiatric works, and the volume, while excellent for the teacher of theoretical psychology in the university, cannot be recommended for use by the medical profession except as background material.

The Baby and Growing Child: Feeding and Health Care for Physicians, Mothers, and Nurses. By Louis Fischer, M.D., Consulting Physician to the Willard Parker Hospital, New York City. Cloth. Price, \$1.50. Pp. 260, with 30 illustrations. New York & London: Funk & Wagnalls Company, 1936.

Numerous simply written books and pamphlets are available for the guidance of mothers in the care of small children. This book is an average example of works of that kind. Most of the statements are correct and are calculated to instruct the mother, at the same time that an effort is made to prevent her from making diagnoses herself. A few of the statements are open to question, as, for example, "Shock, fright and sudden excitement during pregnancy may cause psychic disturbances in the newly born." On the whole, however, no harm could result from reading this book, and in many respects it is so simply written that any mother who can read at all could not fail to understand the purport of the material.

Lehrbuch der Krankenernährung. Herausgegeben von Prof. Dr. C. R. Schlayer und Dr. J. Prüfer, Augusta-Hospital, Berlin. Teil 1: Allgemeine und spezielle Diätetik. Bearbeitet von Chefarzt Dr. H. Delcher et al. Second edition. Cloth. Price, 8.50 marks. Pp. 283, with 3 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1937.

The second edition of this eminently practical book on dietetics followed the first so promptly that few considerable changes could be made; the chapter on reducing and fattening diets has been assigned to Grafe, well known for his researches on metabolic disorders. A new, interesting chapter on the hygiene of foodstuffs and kitchen utensils, prevention of food poisoning and related subjects has been contributed by Ziegelmayer. As dietetics is usually treated in medical schools in a stepmotherly manner, the handy booklet should be of interest not only to dietitians but to medical practitioners as well.

Medical Morals and Manners. By Hubert Ashley Royster, M.D. Cloth. Price, \$2.50. Pp. 333. Chapel Hill, N. C.: University of North Carolina Press, 1937.

This contains some of the addresses and newspaper and magazine articles which the author, an eminent surgeon, has presented during forty years to various audiences. Many of them deal with matters affecting the mutual relations of the medical profession and the public. The subjects vary widely and include the dignity of medicine, muscle, the philosophy of surgery and a few biographic sketches. There is a good deal of charm in many of the essays, although, because of the varied audiences and varied times at which they were written, any cohesiveness is notably lacking. Absence of technical language makes for easy lay reading. The book may be recommended for those who like the philosophic approach to medicine and who have the time to spend in this manner.

Dietetics for the Clinician. By Milton Arlenden Bridges, B.S., M.D., F.A.C.P., Director of Medicine, Detention, Rikers Island and West Side Hospitals, New York. Third edition. Cloth. Price, \$10. Pp. 1,051. Philadelphia: Lea & Febiger, 1937.

The first edition was reviewed in *THE JOURNAL* in 1933. The appearance of the third edition in 1937 amply attests its popularity. The material is well organized and simply written. Revision is adequate. The most striking features of the book are its practicability and the ease with which material can be located through the table of contents or the index. The collaboration of various specialists adds greatly to its value. It should be on the shelves of all those who need to prescribe diets for various diseases.

Facts and Frauds in Woman's Hygiene: A Medical Guide Against Misleading Claims and Dangerous Products. By Rachel Lynn Palmer and Sarah K. Greenberg, M.D. Cloth. Price, \$2. Pp. 311. New York: Vanguard Press, 1936.

The popularity of "100,000,000 Guinea Pigs," which exposed the sales methods and inordinate profits of widely advertised brands, has led to much imitation. The same methods are used here with regard to preparations designed entirely for women. Many of the well known nostrums, some of which have been exposed in the columns of *THE JOURNAL*, are again discussed in a popular vein. The facts on the whole are accurate, but the organization is poor. There could be some advantageous shifting of chapters and some improvement in the style. This book may serve to interest many women in obtaining more reliable information on their "personal hygiene" than that supplied through street car advertisements.

Report of the Medical Research Council for the Year 1935-1936. Paper. Price, 3s. Pp. 172. London: His Majesty's Stationery Office, 1937.

This report is largely a catalogue of the activities of the Medical Research Council for the fiscal year 1935-1936. The activities listed are both numerous and of impressive quality. It is, in fact, difficult to single out from this report any specific research activities of more immediate or ultimate significance than the others. The investigations of influenza at the National Institute for Medical Research concerning the transmission of the influenza virus to ferrets and man already have received wide attention. Considerable activity along nutritional lines is summarized in the report. The detailed results of many of the activities listed have been published, and others are appearing in the current literature at frequent intervals. The report deserves, and should receive, the careful attention of all those who exert any influence on the course of research in this country. Sections of the report are referred to also in the London letter that appeared in *THE JOURNAL* April 24.

The Comparative Feeding Values for Poultry of Barley, Oats, Wheat, Rye and Corn: A Review and Analysis of Published Data. Prepared for the Associate Committee on Grain Research of the National Research Council and the Dominion Department of Agriculture. By Earle W. Crampton, Associate Professor of Animal Nutrition, Macdonald College (McGill University), Quebec. Dominion of Canada, National Research Council, Report No. 29. Paper. Price, 25 cents. Pp. 50. Ottawa: J. O. Patenaude, I. S. O., 1936.

Professor Crampton reports data on the relative values of various grains for feeding chickens. The chief differences in nutritional value are due to the quality of the protein. Also the mineral and vitamin portions of the different grains are important. With proper supplements in the form of protein, salts and vitamins, the different cereal grains studied were about equal in feeding value for poultry. The author concludes that a mixture of two or more of the cereal grains is to be recommended over the use of any one grain alone.

Why We Do It: An Elementary Discussion of Human Conduct and Related Physiology. By Edward C. Mason, M.D., Ph.D., F.A.C.P., Professor of Physiology, University of Oklahoma School of Medicine, Oklahoma City. Cloth. Price, \$1.50. Pp. 177, with 4 illustrations. St. Louis: C. V. Mosby Company, 1937.

This little book, written by a physiologist, is presented with the hope that it will help nontechnically trained persons to orient themselves to some extent in the field of practical psychiatry. It is intended to clarify, for the ordinary person, the principal motivations of his behavior. The author believes that man's behavior is affected almost entirely by three factors: the ego, sex and the herd. Unfortunately, even these objectives do not appear to be constantly in his mind. The result is a discussion often lacking in essential simplicity yet failing to reflect advanced thought in the field. More satisfactory books for laymen interested in this field are available.

Glycerine: Its Role in Medicine. By Milton A. Lesser, B.Sc., and John R. Murphy, M.D. Reprinted from the American Professional Pharmacist, June, July, August, 1936. Paper. Pp. 16. New York, [n. d.]

This pamphlet reviews the wide use of glycerin throughout the years during which it has been employed, either in pharmaceutical practice or as a therapeutic preparation. Glycerin is one of the really essential vehicles for many pharmaceutical preparations. For a booklet of this kind it is conservatively written, but here and there are some errors in description.

There are statements made concerning the medicinal use of glycerin that would be more critical if they were based on comparison with other forms of treatment. For instance, in the treatment of varicose veins glycerin has not received general acceptance. Discounting these details, however, the book may serve as a reference guide for compounding or manufacturing pharmacists. For prescribing physicians it may be of some value for casual reading.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Burn Following Fracture and Therapeutic Application of Heat.—The defendant, a physician, was called to treat a fracture of the arm of the plaintiff's 7 year old son. After he reduced the fracture and set the bone the patient's arm became swollen, and two days after the accident he was taken to the defendant's office. There the defendant placed a cloth over the injured arm and directed a nurse to apply a "heat lamp" for fifteen minutes. At the end of that time the defendant examined the arm and directed that the treatment be continued for fifteen minutes more. When the cloth was removed at the expiration of that period, the patient's arm or hand was found to be badly blistered. The defendant, the plaintiff claimed, rubbed his hand over the affected area and the skin came off, leaving the raw flesh exposed. Ten days later, the patient developed scarlet fever. Another physician treated the patient for that disease, but the defendant continued to treat the arm by means of "heat or diathermy treatments." The patient recovered, except for a permanent scar on the hand. His father sued the physician who had treated the fracture, the defendant in this case. The trial court directed a verdict in favor of the defendant, and the plaintiff appealed to the Supreme Court of Michigan.

The plaintiff contended that the defendant was negligent in that he applied heat for too long a period, despite the remonstrances of the parents and the entreaties of the patient to stop because it was burning him. Evidence was offered to show that after a severe fracture there is an inadequate blood supply to the injured part and that "a hyperemial lamp" is commonly used to supply the deficiency. The defendant testified that thirty minutes was the regular and proper time for the application of heat and that he had applied it for as long as forty-five minutes; but the record does not show the distance from the arm at which the lamp was placed in this case or the usual or proper distance. The record is obscure as to the type of heat therapy used, the terms "heat lamp," "heat or diathermy," and a lamp that gives "only an even heat" and does not give off "penetrating rays" being used indifferently to describe the device used. The defendant testified that a blister had formed when the application of heat was discontinued, but that it would have appeared in any event as a result of the fracture and the subsequent swelling, even if less heat had been applied. To the plaintiff's charge that the defendant rubbed his hand over the blistered area taking off the skin and leaving raw flesh exposed, the defendant replied that he had put his hands over the blister to determine the amount of the underlying swelling.

The plaintiff contended also that the cloth placed by the defendant over the patient's arm when heat was applied was a dirty, infected rag and caused the scarlet fever that developed while the patient was under treatment. The defendant's testimony, however, was to the effect that he had used a piece of stockinet and not an infected rag. It was shown, too, that the period of incubation for scarlet fever is from four to six days and that the patient did not develop the disease until ten days after the allegedly infected cloth had been used. The plaintiff, said the Supreme Court, failed to prove that negligence on the part of the defendant was responsible for the scarlet fever from which the patient suffered.

The plaintiff offered but one expert witness, and under cross-examination his testimony failed to support the plaintiff's

charges. The plaintiff relied therefore, so far as related to his charge of negligence, on previous decisions of the court holding that no expert testimony is necessary in a case in which no question of skill, judgment or practice beyond the knowledge of laymen is involved. The only inference that could be drawn from the scar on the patient's arm or hand, the plaintiff claimed, was that the defendant was negligent. A burning, the Supreme Court admitted, may be so severe and due to such negligence that the case is not exclusively one of medical knowledge. The burning in the instant case, however, was not of that character; the question of negligence was one exclusively for expert testimony. The plaintiff presented but one medical witness and he, when informed of the type of therapeutic lamp used, absolved the defendant from any negligence in connection with its use. There was no evidence to show that the defendant's handling of the blister was not in accord with recognized standard practice in the community.

The judgment of the circuit court, Wayne County, in favor of the defendant, was affirmed.—*Rubenstein v. Purcell (Mich.)*, 267 N. W. 646.

Taxes: Municipality's Right to Impose Occupation Tax on Dentists.—A Kansas law authorizes cities of the second and third class to classify and license for purposes of regulation or revenue any and all occupations, businesses or professions carried on within its corporate limits which are not prohibited by law or which are not specifically or exclusively reserved to the state or county as objects of taxation or regulation. Under this law, the city of Independence by ordinance imposed a license tax on certain named professions, including dentistry. The defendant, a dentist, apparently refused to pay the tax and the city instituted the present proceedings against him to collect the tax and to enjoin him from practicing dentistry until the tax was paid. The trial court gave judgment for the defendant, and the city appealed to the Supreme Court of Kansas.

The fact that the practice of dentistry, said the court, is regulated by a state statute which exacts a license fee of dentists does not exempt dentists from the imposition of the occupation tax sought to be imposed by the city ordinance. A license fee was differentiated from an occupational tax in *Duff v. Garden City*, 122 Kan. 390, 251 P. 1091, as follows:

The question of whether or not the city ordinance is in conflict with the state law depends largely upon whether the charge is an occupation tax or a license fee—whether it is a revenue measure wholly or in substantial part regulatory. If it is an occupation tax, it is not within the prohibition of the statute cited, but, if it is wholly or in part a license fee, regulatory in character, it conflicts with the statute and is invalid. . . .

A regulation charge is one exacted for a privilege or as a condition precedent to the carrying on of the business, and is an exercise of the police power, while an occupation tax is imposed under the power of taxation. 6 Words and Phrases, First Series, p. 4908.

The dental practice act nowhere prohibits a city from imposing an occupational tax for revenue, nor does it reserve to the state the matter of taxing a dentist. The ordinance passed by the city of Independence was held to be valid.—*City of Independence v. Hindenach (Kan.)*, 61 P. (2d) 124.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Clinical Observations in Erythromelalgia and Method for Its Symptomatic Relief. I. Mufson, New York.—p. 483.

Impaired Auriculoventricular Conduction in Rheumatic Fever.—Bruenn observed twenty-two patients with acute rheumatic fever, twenty of whom showed evidence of cardiac damage by the presence of valvular defects. Each patient showed impairment of auriculoventricular conduction in the electrocardiogram. The degree of block varied from prolongation of the PR interval above 0.2 second to incomplete heart block. None of the patients had received digitalis or quinidine. Salicylates were being administered to more than half of them at the time of the observations. The conduction times in these patients and in a control group of seven subjects of comparable age without evidence of heart disease, whose electrocardiograms were normal, were studied after the intravenous injection of atropine or the subcutaneous injection of epinephrine. Two control electrocardiograms were taken, one hour apart. Further records were then made at intervals of from one to four minutes during the periods of observation. Atropine completely abolished the conduction defect in nineteen of the twenty-two patients studied. There was a marked diminution in the degree of block in the one patient to whom the drug was given intramuscularly. In one of the two patients who did not show a reduction in the degree of block after atropinization, the impairment persisted for a year and was probably due to organic changes in the junctional tissues. Three patients, in addition to impairment of auriculoventricular conduction, also showed delay in intraventricular conduction. Atropine had no effect on this disturbance. In three persons who gave evidence of emotional stress at the time of the observations, marked reductions in the PR intervals were noted, despite little or no acceleration of the ventricular rate. Small doses of epinephrine, injected subcutaneously, in five cases produced results similar to those observed in a control group. Larger doses either diminished the conduction defect (two cases) or markedly increased it (three cases). The latter result was not seen in a control group under similar conditions. After moderate exercise, there was some decrease in the PR interval, with a slight increase in the ventricular rate. It was concluded that in cases of acute rheumatic fever impairment of auriculoventricular conduction is due, in part at least, to an increase in vagal tone. It was suggested that the focus of vagal irritation lies in the medulla.

Constriction of Pulmonary Artery by Adhesive Pericarditis.—Gouley discusses a pericardial involvement, observed in six cases, that affects the pulmonary artery. The adhesions which at times surround this artery may be dense and may

actually compress and narrow the vessel to a striking degree. They are almost certainly the cause of physical signs which in his opinion are sufficiently definite to warrant a clinical diagnosis of pulmonary arterial constriction. The pericardial lesions were caused by rheumatic fever. The fundamental pathologic lesion is massive mediastinopericarditis, in which thick, adherent scar tissue surrounds and constricts the pulmonary artery. The pericarditis is rarely limited to the pulmonary artery. Constriction of other vascular trunks may be present. Histologic examination of the pulmonary artery in two cases revealed focal degeneration in the media, involving both muscle and elastic tissue. Examination of the pulmonic area by means of palpation, percussion and auscultation will reveal a variable number of physical signs: (1) a harsh systolic murmur in the pulmonic area, in the second and third left interspaces, (2) a greatly accentuated second pulmonic sound, (3) a diastolic shock in the same area, (4) a systolic pulsation coincidental with the systolic murmur, extending upward in the third and second left interspaces in the direction of the pulmonary artery, which may be followed by (5) a successive retraction of those interspaces, pulsation and retraction having a sinuous appearance, (6) the presence in a few cases of a systolic thrill palpable in the area of the systolic murmur and pulsation and (7) increase in the area of cardiac dullness in the third left interspace indicative of hypertrophy and dilatation of the right ventricle (conus portion). While four patients died relatively early in the course of their rheumatic disease with recurrent acute infection, mechanical obstructive heart failure was probably only incidental or at most contributory to the final outcome. In two patients, however, the adhesive pericarditis with compression of the pulmonary artery was a major factor in the development of cardiac failure.

Study of the Cardia. W. Zeller and G. E. Burget, Portland, Ore.—p. 113.

Pruritus Ani.—The method that Bacon employs in the treatment of pruritus ani is as follows: The patient is placed in an exaggerated left lateral position. The quadrant causing the most distress, or the one appearing most inflamed, is selected for the first injection. The area is swabbed briskly with alcohol or tincture of green soap and dried with sterile gauze. A point just beyond the periphery of the pruritic zone is selected and touched with tincture of iodine. This is wiped off with alcohol, and when the skin has dried an intradermal wheal is made with 1 per cent procaine hydrochloride by means of a small hypodermic needle. A 21 gage needle, 2½ inches in length, to which is attached a syringe containing 1 cc. of the procaine hydrochloride, is slowly advanced beneath the pruritic skin. At this point the procaine hydrochloride is deposited. The needle is held in situ and a 10 cc. syringe containing 10 cc. of triple distilled water is substituted. The contents are slowly injected until the entire amount is used. Should pain or discomfort attend its introduction, injection is suspended for a few seconds. Each quadrant is similarly treated at intervals of three or four days, until a series of eight injections has been given, or until the patient is symptom free. In more than 50 per cent of his 133 cases the author employed only 5 cc. of the distilled water. The duration of symptoms

ranged from nine months to twenty-three years. Following a period of from thirty to thirty-six months, 94.3 per cent of the patients were benefited. Of these, some were completely symptom free and some were improved.

Carbon Arc Treatment in Tuberculosis.—Banyai used carbon arc irradiation in the treatment of ninety-four patients who had pulmonary tuberculosis and twenty-one who had tuberculous pleurisy. The two main factors on which the success or failure of this treatment depends are careful selection of cases and proper technic. Minimal, moderately advanced and even far advanced cases may benefit by this treatment, provided the temperature is not more than 99.5 F. and the general physical condition is satisfactory. Patients with fibrosing or exudative lesions, including cavities, may respond favorably. When one is deciding the problem of the suitability of this treatment, the sedimentation test, the Arneth or Schilling count, the total leukocyte count and the monocyte-lymphocyte ratio are of value. A high leukocyte count, marked "shift to the left" in the Arneth or Schilling count and a greatly increased monocyte-lymphocyte ratio contraindicate irradiation. Other contraindications are fever, rapidly advancing pulmonary tuberculosis, large cavities, acute stage of tuberculous pleurisy, poorly compensated cardiac lesion, marked general debility and ankyloidosis. The adequate dose cannot be predetermined. The optimal exposure is the minimal exposure that elicits the desired therapeutic response. Many failures are caused by prolonged overexposure. Reactions, in general, are most likely to occur in cases of far advanced or exudative lesions. Minor reactions that did not necessitate the discontinuance of the treatment occurred in twenty-five cases, and the treatment was stopped because of reactions in thirteen. The variable course of pulmonary tuberculosis, under any regimen, calls for a close analysis of reaction-like incidents during treatment with a carbon arc lamp. Pulmonary hemorrhage was not more frequent

during treatment than without it. Analysis of the end results in a group of thirty-eight patients whose treatment lasted from three to six months showed that one minimal case became apparently arrested; of the eighteen moderately advanced cases, seven became apparently arrested, two quiescent, three improved and six remained stationary; of the twelve far advanced cases four improved, six remained stationary, one became worse and one patient died. All patients with tuberculous pleurisy made a complete recovery.

Acetyl Beta-Methylcholine Iontophoresis in Arthritis.—Martin and his associates present the results obtained by the treatment of twenty-eight men and fifty-five women having chronic forms of arthritis by means of iontophoretic administration of acetyl- β -methylcholine. They used a 45 volt B battery, with rheostatic control, and an attached ammeter capable of measuring in milliamperes. The material to be electrolyzed, physiologic solution of sodium chloride or 0.25 or 0.5 per cent acetyl- β -methylcholine, was applied to the skin by means of asbestos paper which had been soaked in the desired solution. The circuit was closed and the amperage was slowly raised to 20 or 30 milliamperes, depending on the local sensation of the patient, and kept there for twenty minutes. Generally the patient felt a mild prickling or trickling sensation until the current became constant. Of the patients with infectious arthritis, 57 per cent were improved and some became symptom free; 79 per cent of those with metabolic forms of arthritis were helped and some also became symptom free. The mode of action of the drug is not understood, but it seems likely that it has a stimulating action on the muscles innervated by the parasympathetic system. It is probably not the result of a purely local change alone.

Protamine Insulin.—Newcomb and his co-workers have used protamine insulin in the treatment of thirty-two patients with juvenile diabetes mellitus. The diets were essentially

unaltered for the hospital patients with the change to protamine insulin, although in a few instances redistribution of the carbohydrate between the three meals was found advantageous. Over 2,000 determinations of the blood sugar were made in this study. Estimations of the urinary sugar were made on six hour specimens by Benedict's method. Observations of the effect of varied schedules and types of protamine insulin were carried out. During the first few days after the change from regular to protamine insulin, a higher sugar content was not infrequent, possibly owing to delayed absorption of part of the insulin for more than twenty-four hours. Ketosis developed in one patient, an infant treated for a few days in the home; in this case other factors were felt to be responsible. No allergic manifestations or local reactions were seen. Increased irritability was observed in two children. Many patients did not experience periods of intense hunger, as they did while receiving regular insulin. In instances in which all the insulin could be administered in the morning, the children showed more emotional stability. In twenty-three of thirty-two cases studied, satisfactory control was obtained by a single morning dose. The afternoon and evening activities did not need to be so carefully restricted. During the summer there was a definite decrease in the total dose of protamine insulin, but after the children returned to school an increase in insulin was required.

Apple Diet in Diarrhea in Infants.—Smith and Fried's study is based on ninety cases of enteral, parenteral and irritative-fermentative infection. Seven infants who were admitted in a moribund condition, with acute alimentary intoxication, four patients with proved dysentery and one infant with what clinically resembled dysentery died in spite of the administration of apple diet, specific serum, transfusions and supportive measures. The average length of time that apples were given in cases of fermentative-irritative diarrhea was from seven to eight days, the first formed stool appearing between the fifth and the eighth day. One death occurred in this group. In six cases believed to have the same cause, a starvation period of twenty-four hours was followed by a protein milk formula. No deaths occurred in this group. Eleven infants with diarrhea of infectious origin were treated with scraped raw apple. One infant in this group died. In all, twenty-eight infants, excluding the patients with dysentery, were treated by an apple diet and twelve by starvation followed by the administration of protein milk. There were no striking differences in results. Those in the dispensary were better than those in the hospital. The majority of the patients treated in the dispensary showed improvement in from two to four days, regardless of which mode of therapy was followed.

Diagnosis and Treatment of Kidney Trauma.—Wood asserts that immediately after an injury to the kidney the patient is in shock, complains of pain on the injured side and notes the presence of blood in the urine. There are changes in the pulse

rate, blood pressure and blood picture, depending on the length of time following the injury, the extent of the injury and the degree of hematuria and shock. There is generally abdominal pain associated with tenderness or rigidity, which later may become unilateral or localized over the injured area; and in severe injury to the kidney, not infrequently a mass is present in the loin. Gross or scanty hematuria is present but should not be interpreted as an index to the extent of the injury. In occasional cases emergency methods must be employed immediately to combat shock, arrest hemorrhage and handle associated injuries of the viscera. When plain roentgenograms disclose a mass with obliteration of the psoas muscle shadow, an excretory urogram is indicated. In the author's series of twenty-five cases, excretory urography was employed in seventeen. Diagnostic shadows were disclosed in twelve cases on the injured side, and in three cases a preoperative diagnosis of ruptured kidney was made possible. Of five patients whose excretory urograms failed to reveal satisfactory shadows, three recovered without operative intervention and two had the kidney removed. Parenchymal damage of the kidney results in complete or temporary anuria, hindering the excretion of the opaque solution and increasing the difficulty of interpretation of the films. This is to be expected in cases of severe trauma and in cases of marked contusions without rupture of the renal pelvis. Sufficient opaque solution is excreted by the uninjured portion of the kidney ruptured transversely to outline the point of rupture. Strict attention to the clinical course is imperative, and examinations at frequent intervals are essential when one is outlining the course of treatment. Absolute rest in bed is essential until hematuria ceases and all symptoms have subsided. Pain is controlled by morphine. Body fluids are supplied by increasing the fluid intake by mouth or by subcutaneous infusion. Abdominal distention and intestinal evacuation are handled preferably by enemas rather than by drastic purgation. An operation should be performed immediately in desperate cases only, and a blood transfusion should be given during the operation. There were three deaths among the twenty-five cases, two operative and one nonoperative. One operative death was due to head injury and the other to postoperative pneumonia. The nonoperative death was due to unrecognized rupture of the kidney, injury to the peritoneum and the mesentery.

Metastatic Pulsating Tumors of Sternum.—Roth and Davidson report the presence of a pulsating tumor of the sternum metastatic from a hypernephroma. The development of cerebral symptoms suggestive of a tumor of the brain was ascribed to another metastasis from the same primary tumor. However, the necropsy demonstrated that this was not the cause and that the cerebral symptoms were produced by a separate primary neoplasm—an astrocytoma. Although it is theoretically possible for a metastatic hypernephroma of the sternum to be a solitary metastasis and for surgical removal of this tumor together with removal of a recognized primary tumor to result in a cure, it seems that small primary growths, difficult to demonstrate, are more apt to be complicated by osseous metastases. Five of the six reported cases appear to substantiate this conclusion, since in none was there any clinical evidence of renal pathologic changes; the authors' case is exceptional in that clinical symptoms directed their attention to the kidney. What clinically appears to be a solitary metastasis from a hypernephroma may in reality be accompanied by multiple hidden metastases, and therefore surgical intervention is inadvisable. In the presence of a demonstrable metastasis from a hypernephroma, irradiation is indicated as a palliative measure.

Water Metabolism in Surgical Patients.—Nesbit studied a series of patients undergoing a variety of surgical operations to determine the amount of fluid lost during operation and the immediate postoperative period. The average loss of fluid by vaporization was 700 cc., and the average total loss of fluid, including blood, vomitus, urine and vaporization, was 1,000 cc. It is thus obvious that an imbalance between available fluids and total fluids lost is considerable. The fluid lost can be reduced if the extra blankets of the old-fashioned "ether bed" are done away with and the patient is transferred directly from the operating table to a bed warmed with hot water bottles. In considering available water for the surgical patient, it must

be remembered that the usual 1,000 to 1,500 cc. available from the food of a normal diet may be lacking entirely because of dietary restrictions. Patients who enter the hospital in a dehydrated condition present an additional problem in water balance. Water balance studies on normal subjects showed that signs of serious dehydration were produced when the water loss was equal to approximately 6 per cent of the body weight. This loss should be restored by additional fluid intake.

Female Bladder and Urethra.—In a study of 395 female patients with urinary disturbances (250 in the gynecologic clinic and 145 in the urologic clinic), Fetter and Lintgen observed that the bladder was entirely responsible for the symptoms in forty and the urethra in fifty-six cases. Both organs were partly responsible for the symptoms in 189. Lesions of the generative organs were responsible etiologic factors in thirty-nine cases. Other organs not connected with the urinary and generative tracts caused the symptoms in nine. The most prominent symptom was frequency of urination. For a correct diagnosis it is necessary to obtain a thorough urinary and gynecologic history and a catheterized specimen of urine. Urinary symptoms during parturition or the puerperium may be due to infection, obstruction or injury to the bladder, trigon or sphincter muscle of the urethra following delivery. Intravenous urography, cystography and urethrography will often demonstrate the lesion.

Pulmonary Symptoms from Ulceration into a Bronchus.—According to Vinson and Toone, ordinary methods of examination fail to reveal the cause of many pulmonary symptoms. A cough, fever, hemoptysis and thoracic pain may be present without evidence of thoracic disease on physical or roentgenoscopic examination. Unless a chronic pulmonary lesion is associated with tubercle bacilli in the sputum, direct visualization of the tracheobronchial tree is indicated. Although roentgenoscopic study of the lungs following the injection of iodized oil into the tracheobronchial tree may reveal obstruction or dilatation of the bronchi, it is rarely possible to determine with accuracy the cause by this method of examination alone. Bronchoscopy is necessary for diagnosis in cases of ulceration of hilar lymph nodes into a bronchus. The underlying cause of this lesion is usually tuberculosis, which produces erosion of the wall of the bronchus. Enlargement of nodes resulting from lymphoblastoma may produce ulceration of the wall of the bronchus with spontaneous expulsion of a portion of the node. The diagnosis of this disease has also been made by removal of a portion of the gland which was seen at bronchosopic examination. Tuberculous nodes without calcification may protrude through the wall of a bronchus and are always located on the mesial wall of a main bronchus, bleeding readily when traumatized. Many of them are associated with pulmonary hemorrhage. The authors have not been able to prove the tuberculous nature of these lesions by examination of tissue during life, but in two instances tuberculosis of the hilar nodes was demonstrated at necropsy.

Influenza Virus Antibodies.—The recent extensive epidemic of influenza has afforded an opportunity to Hoyle and Fairbrother to confirm the observation of Laidlaw and his colleagues (1933) that the disease is due to a filtrable virus. Their investigations have been directed mainly to the isolation of the virus and to determining the relation between the presence of antibodies and protection. Not only was the virus isolated from a number of cases but there was also a definite increase in the antibody titer of convalescent serums as demonstrated by complement fixation tests. In a few instances it was possible to examine the serum before and after an attack, and in each case an increased titer was recorded. The results suggest that individuals with a low antibody titer are more susceptible to infection than those with a high titer. This may be of some practical value, as recent work indicates that prophylactic vaccination may soon be available for general application. Francis and Magill suggest that this increase in circulating antibodies is accompanied by an increased ability to combat the natural infection. It follows, therefore, that if it is possible to differentiate immune from susceptible persons the application of active immunization will be assisted. The complement fixation test is the most satisfactory of the tests at present available for this purpose. A titer of 1 in 16 or over suggests a high degree of immunity, while it seems probable that titers of 1 in 4 or 1 in 8 may represent an immunity sufficient to prevent infection in a mild epidemic.

Blood Pressure Following Coronary Thrombosis.—Palmer studied the blood pressure of 212 patients who survived an attack of coronary thrombosis by at least three months. The incidence of hypertension (160 mm. systolic and/or 100 mm. diastolic) as determined by readings made before or at any time after the attack was found to be 73 per cent. More than half the patients showed hypertension during the first year. The hypertensive group included 37 per cent of those less than 50 years of age and from 78 to 84 per cent of those in the next three decades of life at the time of the attack. All except one of the twenty female patients had hypertension. The average course of the blood pressure during ten years after coronary thrombosis (not including the first month following the attack) has been plotted. The systolic pressure showed a slight rise during this period, while the diastolic showed a slight fall. The average blood pressure for the series before the attack was probably about 170/100. Although on the average the

prior levels were not regained during the ten year period, they were in a few cases actually exceeded.

Sciatic Scoliosis.—Wardle tabulates and divides a series of twenty-six cases of sciatic scoliosis into two broad types, those with sciatic pain and an obvious scoliosis and those with sciatic pain in which a slight degree of lateral deviation of the spine became apparent during examination. The clinical observations in these cases oppose the theory that sciatic scoliosis is due to an arthritis of the lumbar intervertebral joints, mainly on the ground that a true arthritis should produce complete limitation of movement; it is unlikely that the symptoms would always be unilateral if arthritis were present, and that, if such arthritic edema were causing pain by compression of nerve roots, it is extraordinary that the fourth and fifth lumbar roots appear to be the only ones ever affected. The direction of the deformity may mean something in elucidating the cause of this condition, for there are two possible explanations of the muscle spasm and deformity. Irritation of the affected nerve roots by pressure could produce muscle spasm reflexly on the same side of the body as the pain, and, in the second place, an involuntary effort on the part of the patient to relieve pressure by opening up the neural foramen on the affected side would produce contraction of the muscles on the opposite side of the body to the pain—a contralateral deformity.

Nonepidemic Typhus.—Von der Borch observed fourteen cases of a nonepidemic form of typhus, which closely resembles Japanese river fever or tsutsugamushi clinically and serologically. The vector is unknown, but the suggestion is made that it is mite borne, as species of Trombiculae are commonly found on bird, beast and man. There appears to be no seasonal incidence, as cases have been scattered all through the period from January 1935 to June 1936. Fatal termination appears unlikely in robust and moderately young patients, although they may appear very ill. Elderly alcoholic subjects have a poor chance of recovery. Death ensues from toxemia, pneumonia and cardiac failure. All patients have shown a typical lesion, single in thirteen cases and duplicated in only one case. The lesion is always characterized as follows: A central, dry, circular eschar from one-fourth to one-half inch in diameter is surrounded by a dull red ring of lymphangitis approximately one-eighth to one-fourth inch wide, slightly raised above the surface of the skin. From this sometimes radiate short, dull red pseudopodia. The lesion occurred on the axilla in five cases, the calf of the leg in four, the thigh in two cases, the scrotum in two and at the waistline in one case. No cases of typhus have been observed among natives, although a careful watch has been kept. All the cases, with two exceptions, have occurred in and around Wau. The conditions under which infection has apparently occurred are similar in all cases, with the exception of three cases in women. The male patients were associated with work necessitating the clearing of virgin bush for development or prospecting purposes. The incubation time of the disease is difficult to determine, as can be well understood; but from the clear-cut history of one patient who paid a visit to a known infective area on one day only, it is apparently ten days.

 Hydatid Cyst of Lung: Case. J. Lanos.—p. 497.

Pulmonary Abscesses.—Lévy-Deker has devised a soft sound to be introduced into the larynx, trachea and bronchi under conditions similar to those in tracheobronchial endoscopy. The small caliber of this sound permits a much deeper penetration (from 10 to 15 cm.) into the bronchial tree and makes it applicable to almost all patients. Owing to the small amount of cocaine employed, the patient sustains no shock and pulmonary infections may be drained that could not otherwise be reached with endoscopy. The sound is made of very fine rubber. It is simple for aspiration and for injection of drugs and is double for lavage. The sound is marked in two places, one at 18 cm. corresponding to the opening of the glottis, the other at 30 cm. indicating the tracheal spur. The remaining 15 cm. is for bronchial catheterization. After nasal and pharyngolaryngeal anesthesia the oiled sound is introduced through the nose until it appears below the uvula. At this moment the patient's tongue is drawn forward and the sound is inserted through the epiglottis into the larynx. The patient takes a deep breath and the sound enters into the trachea; if there is a light coughing reflex a few drops of cocaine solution will subdue it and permit the sound to enter either of the bronchi. All this is done under fluoroscopic control. For aspiration another tube with an aspirator is attached to the sound. Lavage can be performed without fluoroscopic control, the patient lying on the catheterized side and from 60 to 200 cc. of tepid physiologic solution of sodium chloride being injected. In the same manner drugs or opaque fluids may be introduced. However, in certain congestive cases weak solutions of cocaine may not be sufficient or, when the epiglottis is small, a speculum may have to be employed.

 *Action of Normal Adult Pig Serum in Typhoid. F. Bec and J. Dulcy.—p. 126.

Pig Serum in Typhoid.—Bec and Dulcy observed that during castration of pigs no aseptic precautions are used and that the animal's peritoneum is often soiled with manure. And yet the animals do not contract any disease. There are times when many piglets fall victims to so-called hog cholera, from which the adult pigs are spared. As the symptoms of hog cholera greatly resemble those of human typhoid, the authors conjecture that pigs which have survived the disease are also immune against typhoid. Therefore they doubt whether the *Eberth bacillus* is the cause of typhoid. It may be merely an end result, while the real cause is a filtrable virus or a modified pathogenic colon bacillus. This is the reason why the authors insist on instituting pork serum treatment soon after the typhoid symptoms appear and never wait for sero-diagnostic confirmation. They distinguish two pathogenic germs: virus and bacillus. Vaccination against the bacillus is sufficient to develop resistance. But once the disease is established, pork serum is the only recourse.

 Role of Corticodienecephalic and Diencephalohypophysary Correlations in Regulating Waking and Sleep. A. Salmon.—p. 509.

Lumbar Sympathectomy in Pott's Paralysis.—Encouraged by Diez's reports (1929), Jiano and his associates performed two lumbar sympathectomies in advanced cases of Pott's disease with paraplegia. Both cases showed typical motor, reflex and tactile disorders. Roentgenograms of both showed partial destruction of lumbar vertebrae. A right lum-

botomy was done under ether anesthesia. The sympathetic chain was found between the vena cava and the spinal insertion of the psoas. The sympathetic is isolated by means of small tampons, the communicating branches are sectioned and the sympathetic is extirpated together with the second and third lumbar ganglions. No drain is necessary on closing. Twenty-four hours later the patient is able to move the toes and both feet. On the next day the legs can be flexed. Gradually the amplitude of the movements increases, the reflexes become lively and the Babinski reflex is negative. About two weeks after the operation, the patient can keep upright when supported and even take a few steps. After three months all functions are restored. Owing to persisting vertebral pains, an osteosynthesis was done in one case. The intervention directed against the sympathetic determines a physiologic modification in the blood provision of the spinal cord. The healing of the paraplegia is then explained by the coming into play of a system of arterial anastomoses even when the seat of the vertebral lesion is above the sympathetic level.

- *Epileptic Crises from Camphor Bromide. P. Pagniez, A. Plichet and A. Varay.—p. 585.
 Study of Lipidoses in Neuropathology: I. Phospholipidoses. L. Van Bogaert.—p. 587.

Epileptic Crises from Camphor Bromide.—Pagniez and his associates warn against the indiscriminate use of camphor bromide and point out its epileptogenic properties. They cite three cases in which camphor bromide was given orally for ailments other than epilepsy and in which epilepsy was never before observed. The observations are typical, with biting of the tongue and tonic and clonic convulsions, foaming at the mouth, stertor and semicoma. Injected under the form of oily solution into the peritoneum or the cerebrospinal cavity, camphor bromide shows only feeble toxicity; but given intravenously or in alcoholic solutions it may easily elicit convulsions. Muskens made similar experiments on cats and found that a dose of 0.5 Gm. increases the animal's tactile and acoustic irritability. With a higher or repeated dose it is possible to obtain a complete epileptic crisis or a fatal issue. It is likely that some persons are intolerant to camphor bromide, and therefore it is advisable to test the susceptibility of the patient with weak and fractionated doses before administering therapeutic doses.

 Pyloric Stenosis from Ingestion of Hydrochloric Acid: Case. R. Gatta.—p. 593.

Buffer Value of Gastric Juice.—According to Zorzi, the knowledge of the buffer value of the gastric juice is of value in studying gastric acidity, of which it is a regulating factor. The buffer factor has been known as "differential acidity" or "combined gastric acid." All gastric juices, spontaneously secreted or induced by administration of a test meal, contain buffer substances, the proportion of which depends on the amount of proteins contained in the gastric juice or in the administered test meal. The buffer value can be determined by titrating the total acidity of the gastric juice by phenolphthalein. It equals total acidity less free acidity in acid gastric juices (those with a p_n lower than 3). It equals total acidity plus acid shortage in anacid gastric juices (those with a p_n higher than 3). The author made determinations of the buffer substances of the gastric juice in 400 patients suffering from gastric disorders (cancer excluded). The buffer value is the lowest in the gastric juices removed from a fasting stomach as well as after a test meal without proteins (15 or 20 degrees of acidity). It is the highest in those which are removed after administration of Ewald's meal (70 or 80 degrees of acidity). A clinical relation between the buffer value and the gastric disturbance in a given case cannot be found. The variations of the buffer value in the gastric juice depend on

the laws of titration, the secreting activity of the stomach and the pyloric evacuation. The buffer value is given by an endogenous factor, which does not change, and an exogenous (alimentary) factor, which changes. The buffer value is an index for the functions of evacuation of the stomach of more precision than the roentgen examination of the organ. Because of its relations with the p_n of the gastric juice, it is of value in indicating the physiopathologic significance of the gastric p_n in its relation to gastric acidity.

*Frequency and Importance of Certain Humoral Variations After Operations. U. Bracci.—p. 181.

Multiple Visceral Lesions from Contusion of Abdomen: Clinical and Statistical Study. C. Mastrosimone.—p. 210.

Postoperative Humoral Variations.—Bracci reviews the various theories on the cause and pathogenesis of postoperative humoral variations, with especial reference to the rôle of chloremia in producing hyperazotemia. From observation of a large number of patients the author concludes that postoperative azotemia appears in about 80 per cent of the cases. As a rule it is slight, and in only a few cases is there hyperazotemia. The frequency of azotemia is related to the seriousness of the operation, and the quality (predominance of urea of pre-urea substances) depends on the organ on which the operation was done. Postoperative toxic conditions are rare. They depend on the entrance of toxic products and incomplete disintegration of proteins in the blood. Several biochemical and other factors are involved in the development of postoperative hyperazotemia. Anesthesia also plays a part, but the rôle of chloremia in producing hyperazotemia is secondary. Up to the present the appearance of humoral changes after operations cannot be predicted or prevented. Further work on the subject is advisable in order to prevent and control humoral postoperative complications.

Atrophy of Muscles of Thenar Eminence in Nervous Leprosy.—DeSouza Campos and Longo emphasize the importance of electrical examination of the muscles in the early diagnosis of nervous leprosy. According to the authors, all cases of muscular atrophy have to be subjected to electrical examination, which is the best topographical method for the diagnosis of nervous leprosy as well as for determining the evolution of the disease. They report five cases of atrophy circumscribed to the muscles of the thenar eminence as a symptom, early or late, of leprosy of the ulnar nerve. From their clinical study as well as from a review of the knowledge on the anatomy of the hand, the authors conclude that in their cases only the terminal motor branches of the ulnar nerve and the interosseous posterior nerve were involved in the leprosy degenerative process.

Defense Powers of Nurslings Against Infections.—Cosack points out that the unique position of the defense powers of young nurslings is reflected in the therapy. It is observed again and again that the young organism reacts differently from the adult organism to therapeutic measures, which aim to increase or support the defense powers. As an example the author chooses the therapy of erysipelas, the most acute disease

of young nurslings. He shows how various therapeutic measures exert a different effect in nurslings and in adults. Whereas, for instance, serotherapy and irritation therapy fail in the youngest nurslings, blood transfusion seems to be especially suited for the organism of nurslings. By means of a preparation for irritation therapy, it was demonstrated that the nonspecific defense power is weak in young nurslings. It was possible to differentiate three developmental phases of internal maturation. In the new-born phase, the humoral as well as the cellular defense mechanisms have only a slight reactivity. This phase has been termed that of physiologic areactivity. The second phase comprises the age of young nurslings and it is chiefly characterized by strong leukocytic reactions. During the third phase, which includes the older nurslings and young children, the humoral defense mechanisms reach their full development while the cellular ones decrease constantly. In adults the latter disappear completely and leave the field entirely to the purely humoral reactions.

Immunotherapy of Whooping Cough.—Keller recorded in curves the coughing attacks and the antibody content of sixty-three children with whooping cough, forty-three of whom had been treated with a whooping cough vaccine and twenty of whom had not been vaccinated. The antibody content was determined by means of the complement fixation reaction. In the children who had not been vaccinated, the comparison of the two curves revealed that neither the antibodies in the blood nor those in the tissues are the cause of the hygienic processes and consequently of the cure. But although the antibodies as such are of no importance for the essential process of hygienogenesis, the peak in the antibody curve indicates the onset of the curative process. In the children who had been vaccinated, the following observations were made: 1. The specific antibodies that are produced by vaccination and demonstrable by the complement fixation test are identical with those that are formed during the spontaneous infection. 2. The formation of antibodies, which is elicited by the vaccination of whooping cough patients, is so rapid that the appearance of the antibodies in the blood in many cases has not the same significance as in the children who have not been treated with the vaccine. 3. In view of the observations on those who had not been given vaccine, the vaccination can be pronounced as efficacious only if the peak of the antibody curve and the subsidence of the attacks of coughing concur. This apparently takes place if the vaccine is administered after the cough has already appeared, for in spite of the relatively late vaccination the peak of the antibody curve is reached earlier than in those who have not been vaccinated and the spontaneous hygienic processes are accelerated. 4. If the vaccine is administered after the antibody titer has reached spontaneously a high level, a considerable although temporary reduction in the titer usually takes place immediately. 5. In case of complications with other disorders, such as pneumonia or bronchitis, and in young nurslings, the treatment with vaccine fails. 6. Prophylactic vaccination, even if it produces a high antibody titer and is performed long enough before the infection, proves inadequate to prevent whooping cough. 7. Although the therapeutic use of whooping cough vaccine is limited, its complete rejection is not justified.

Treatment of Children with Pneumonia.—According to Jochims, the fresh air treatment of young children with bronchopneumonia has gained favor in recent years. There are cases in which prolonged exposure to fresh air causes renewed impairment of the circulation or even collapse and also disturbances in the general condition. The author reasoned that

this might be avoided if, after several hours' exposure to the cold fresh air, the child was brought again into a warm room and then again into the cold fresh air. This led him to the development of the treatment by air stimuli, that is, by changes between cool fresh air and warm room temperature, the change being made at intervals of six hours. This treatment was employed in twenty-six children. It is important that the change from one temperature to the other is made quickly, for the cold air must exert a stimulus on the skin; it should produce a noticeable reduction of the cutaneous temperature. On the whole, the important factor is not so much the absolute temperatures, but rather the extent of the difference. After the children are brought from the lower temperature into the warm room, the cheeks show a better blood perfusion, which lasts several hours and is indicated by the reddish color of the skin as well as by the cutaneous temperature. The temperature of the cheeks increases as much as 4.8 degrees C. above the initial value. The treatment with air stimuli or air changes is used with good results in children with bronchopneumonia. However, it is contraindicated in premature births and in nurslings with a still inadequate temperature control. Children who are in collapse or those in whom collapse threatens are likewise unsuited for exposure to cold air. In children with latent spasmophilia, the air stimuli should be employed only with extreme caution.

Pathology of Hypophysial Disorders.—Falta criticizes Erdheim's opinion regarding partial hyperpituitarism. He does not deny that acromegaly is the result of a hyperfunction of the eosinophilic cells, but he questions whether the growing eosinophilic tumor by its pressure on the other types of cells of the adenohypophysis complicates the partial hyperpituitarism by hypopituitarism and whether this explains the later development of cachexia and genital impairment. He points out that this assumption is contradicted by the fact that in the initial stage of many cases of acromegaly there exists an increase in the genital function and that this function frequently is retained to the late stages of the disease. Moreover, if acromegaly is accompanied by a disturbance in the genital function, this disorder is of a different nature than is the case in hypophysial cachexia, which represents the opposite of acromegaly and is probably caused chiefly by the abolishment of the function of the eosinophilic cells. The cachexia that develops in the later stages of typical acromegaly differs from the cachexia that develops in case of destruction of the anterior lobe of a hypophysis. Then there is a combination of acromegaly with eunuchoidism; but even in this case the eunuchoidism is not produced, as assumed by Erdheim, by a pressure of the growing eosinophilic tumor on the other types of cells of the adenohypophysis but is rather an independent entity. The author is convinced that eunuchoidism as such has no connection with the hypophysis but is the result of a defective primordium of the trophic center of the gonads in the hypothalamic region. Further he takes up Cushing's syndrome, calling attention to the fact that the pathologic anatomy does not provide an adequate explanation, for there are cases with basophil adenomas in which Cushing's syndrome does not develop. On the other hand, a case has been described in which there was not only an increase in basophilic cells of the anterior pituitary, but basophilic cells were found disseminated from there into the hypothalamic region and were detected also in the adrenal cortex and in the kidneys. In discussing the various functions of the hypophysial hormones the author stresses that the action on the metabolism should not be overlooked. In the conclusion he expresses the opinion that it is not necessary to differentiate between anterior hypophysial substances that have been extracted from pregnancy urine and the extracts of the anterior lobe of the hypophysis. He found that with a substance extracted from pregnancy urine it was possible to produce nearly all the effects which can be produced with the various extracts

obtained by different methods from the anterior lobe of the hypophysis, such as the action on the basal metabolism, the anti-insular action, the gonadotropic action and the growth promoting action. He suggests that the numerous substances obtained from the anterior pituitary by various methods of extraction might be derived from one basic substance.

Pseudoparasites. V. Jensen.—p. 348.
Morgagni's Syndrome (Hyperostosis Frontalis Interna, Virilitas, Obesitas). P. Levison.—p. 352.

Deep Otogenic Inflammation of Temporal Bone.—Lund discusses simple petrositis and osteitis of the petrous portion of the temporal bone on the basis of fifty-four cases comprising thirty-eight cases of acute or subacute suppuration of the middle ear, thirteen of simple chronic and three of cholesteatomatous suppuration. In the fifty-four cases eighty-nine foci were emptied, fifteen anterior and seventy-four posterior, the greater number of interventions on the posterior foci being partly due to their easier accessibility. The main symptom in deep osteitis is pain, differing in character and location from the usual ear pain. It is generally neuralgic, most often violent. The most common localization is one or more of the fields of the trigeminal branches. In thirteen cases in children under the age of 10 years, there was no definite statement as to pain. In part of the second group of twenty-four adults there was pain, sometimes violent, but indefinite. In the third group of nineteen patients, typical petrositis pain was established; fourteen of these had acute suppuration of the middle ear, the typical pain appearing in eleven during the first days of the suppuration and in three on the seventeenth, the thirteenth and the forty-first day, respectively. These pains cease spontaneously or after the operation on the ear, permanently in many cases; in others they recur. When the field of all three trigeminal branches is affected, the presence of a disturbance of the gasserian ganglion is likely; it is certain if disturbances in sensitivity are established also in the trigeminal fields. The neuralgic pain in the orbits, emphasized in the literature, occurred in only four cases, in two of which the apex was affected. In three cases there was no orbital pain in spite of total petrositis. In emptying focus VI, especially when the osteitis continues into focus III, which is frequent, the facial nerve is sometimes laid bare above the styloid foramen, usually, without lesion of the nerve, causing a postoperative paralysis of the facial nerve as seen in six cases. The prognosis is favorable. In nineteen cases there was pronounced disorder of the labyrinth, with complete destruction of the labyrinth in seven and fistulous breaking through to the labyrinth in two. In case of labyrinthine disturbance during the course of suppuration of the ear, every effort should be made to determine whether or not petrositis is present. If apicitis is not diagnosed before paralysis of the abducent nerve is manifest, the case will often be one of marked meningitis. Petrositis in the early course of suppuration of the middle ear, without actual osteitis, has a tendency to spontaneous recovery. Even at a later stage, when there is true osteitis in the temporal bone, i. e., from the third to the sixth week, when operation on the mastoid process is indicated, the prognosis is good without deep intervention. In the subacute stages of the osteitis the disorder is so variable in localization and extent that the prognosis is uncertain. In the first stage of acute petrositis, paracentesis often results in recovery.

THE XANTHINES (THEOBROMINE AND AMINOPHYLLINE) IN THE TREAT- MENT OF CARDIAC PAIN

HARRY GOLD, M.D.

NATHANIEL T. KWIT, M.D.

AND

HAROLD OTTO, M.D.

NEW YORK

An endeavor was made in this study to secure evidence on the question of whether the xanthines relieve cardiac pain.

SELECTION OF PATIENTS

The subjects were 100 ambulant patients in attendance at the cardiac clinic, in whom the diagnosis of arteriosclerotic heart disease with cardiac pain was made, in accordance with the nomenclature and criteria adopted by the New York Heart Association.¹

They were selected from a total case load of approximately 700 patients, representing an average sample of the cardiac clinic population, comprising several racial groups, both native and foreign born. The study was conducted during a period of five years. The duration of the study in any given case varied from two to fifty months, the average being fifteen months.

Some of the characteristics of the whole group are listed in table 1.

None of these patients had signs of congestive heart failure. Only patients with pain on effort were studied, although it was realized that some cases of true cardiac pain were excluded by this restriction. However, this measure served further to insure against the inclusion of patients in whom the thoracic pain might be of non-cardiac origin.

The severity of the pain varied greatly, from mild substernal pressure or discomfort induced by moderate effort, only slightly interfering with the patient's ability to carry on (1+), to excruciating pain induced by the slightest effort, occurring also when the patient was at rest, so as to cause almost complete incapacity (3+).

Careful questioning of the patient at every visit to the clinic made it possible to exclude those cases in which there was reason to believe that cooperation in the uninterrupted use of whatever drug was issued and in the accurate reporting of any omissions was not sufficiently faithful for the purpose of this study.

If the xanthine should produce a moderate improvement in the efficiency of the coronary circulation, the

effect of this might conceivably escape detection in individuals engaged in very heavy work. From this point of view our subjects were particularly favorable for this study, since most of them, as shown in the table, were not engaged in any occupation.

GLYCERYL TRINITRATE TEST

Early in the course of the study it was believed desirable to restrict the selection of patients to those who could establish their qualifications for service in such a study as this by their ability to distinguish between the efficacy of glyceryl trinitrate taken under the tongue and a soluble placebo tablet taken in the same manner for relief during attacks of pain. The discovery of several patients who found the two equally effective among those who had suffered an attack of coronary thrombosis and were subject to thoracic pain on effort led us to abandon this restriction.

The results obtained in sixty patients in whom the glyceryl trinitrate test was made are of some interest. These patients received glyceryl trinitrate tablets, $\frac{1}{100}$ or $\frac{1}{150}$ grain (0.6 or 0.4 mg.), which they were directed to take under the tongue at the onset of an attack of pain. In many of these cases, periods of glyceryl trinitrate testing were alternated with periods in which a soluble placebo was dispensed. The duration of these periods was from one-week to several weeks in each case. The results are presented in table 2. Of the sixty patients, forty-nine (82 per cent) reported relief by the use of glyceryl trinitrate during attacks. Of eighteen cases in which the soluble placebo was also used, fourteen (78 per cent) reported relief of symptoms. This is not a strictly valid comparison of the relative effectiveness of the placebo and glyceryl trinitrate because of the small number of cases in which the placebo was used. Nevertheless these results give some idea of how often a placebo taken under the tongue may be judged by the average clinic patient to afford relief during attacks of cardiac pain.

The qualification of the patient to testify regarding the efficacy of a vasodilator drug is, no doubt, best established in those cases in which the attack of pain is such as to enable the patient always to distinguish between the glyceryl trinitrate and the placebo. However, the fact that the patient believed that he obtained partial or even complete relief with the placebo during brief attacks of pain does not necessarily disqualify his testimony in a study of theobromine. A patient who is subject to brief attacks of cardiac pain on effort which necessitate immediate interruption of the physical activities and which, in turn, leads to rapid cessation of pain, may easily be in error in judgment regarding the efficiency of a drug used to terminate the attack. Such a patient, however, need not necessarily have difficulty in distinguishing a potent from an inert agent when the

1. Criteria for the Classification and Diagnosis of Heart Disease.

results compared are changes in the frequency of attacks and in the capacity for effort without distress. These individuals, therefore, are entirely suitable for the study of the effects of a drug like theobromine, which is presumed to act over a protracted period.

DRUGS AND OTHER TREATMENT

Most of these patients had been in attendance at the clinic for a long time when the study was started, and many of them were already subject to restrictions in

diet and effort. No advice was given for modification of habits or activities during the course of this study.

The choice of a xanthine presented a problem. The results of animal experiments dealing with their effect on the coronary circulation are conflicting. Smith, Miller and Graber² found theophylline preparations more effective than other xanthines. In contrast, Gilbert and Fenn³ and Heathcote⁴ found theobromine preparations more effective than those of theophylline. There is also considerable divergence of opinion in the clinical literature on the relative merits of different members of the xanthine group. It has been stated⁵ that therapeutic effects may be produced by one member when another has failed. Each has its adherents (diuretin,⁶ theophylline,⁷ theobromine⁸). The one that appears to be most popular at the present time is theophylline with ethylenediamine, although some⁵ maintain that theobromine or its preparations are equally effective and sometimes more effective.

The drugs were dispensed in the clinic. In this study theobromine in the form of a 5 grain (0.3 Gm.) tablet was used in all the cases, and in twelve of them tests with aminophylline (theophylline with ethylenediamine), given in 1½ grain (0.1 Gm.) tablets, were also carried through. The total daily dose of theobromine varied from 15 to 60 grains (1 to 4 Gm.), given in single doses of from 5 to 15 grains (0.3 to 1 Gm.) at intervals of about six hours. The highest daily dosage of theobromine was from 15 to 25 grains (1 to 1.6 Gm.) in

26 per cent of the cases, 30 grains (2 Gm.) in 53 per cent, and between 40 and 60 grains (2.6 to 4 Gm.) in 21 per cent. The highest total doses of aminophylline were 9 and 12 grains (0.6 and 0.8 Gm.) daily in all cases except one, in which the highest dose was 6 grains (0.4 Gm.). These were given in single doses of 3 grains (0.2 Gm.) three or four times a day. These doses correspond to the high doses given by others and exceed the doses used in the majority of reports in the literature.

The xanthines were given in courses lasting from one to twenty-five weeks, the average lasting three and one-half weeks. Some patients received as many as seven courses; the average was two courses for each patient. Several courses of treatment with the xanthine and the placebo were carried through, especially in those cases in which obvious factors that might vitiate a valid comparison existed, such as a change of weather or of work. In all, 209 courses of treatment with the xanthines were given. Each course was alternated with a period in which the patient received various agents such as sodium salicylate, acetylsalicylic acid, calomel, quinidine, cascara, mixture of rhubarb and soda (N. F.), digitalis, phenobarbital or codeine. In each case a comparison was also made of the efficacy of the xanthines with that of lactose.

The physical characteristics of the oral placebo that we used as a routine, a tablet of lactose, were not identical with those of the xanthine. It was not considered necessary to have them identical for those patients who reported no improvement while taking a xanthine. However, it was essential to take the factors of size, shape and taste into account in the subsequent testing in cases in which improvement occurred during the use of the xanthine but which failed to continue when the medication was changed. The validity of the control was materially enhanced by the fact that the duration of the courses with the placebo and the xanthines was fairly long and that courses of each were

repeated frequently, at different seasons of the year, and under other conditions as nearly comparable as possible.

METHOD OF SECURING DATA

The method of securing data proved to be by far the most laborious aspect of the whole work. The validity of the results in this study depends chiefly on the nature of the questions that the patient was asked and the accuracy of the answers. No effort was spared in the endeavor to secure the patient's most accurate judgments, since these judgments regarding changes in the severity of a subjective symptom formed the factual data on which the analyses are based. It was fully realized that the study could be no better than this part of the work.

It is not feasible to describe in detail the technic of the questioning; it varied from patient to patient. It should be stated, however, that the hurried interrogation of the average clinic routine history proved entirely inadequate for our purpose.

Some general principles that we endeavored to take into account may be mentioned:

The study was started during a period which the patient regarded as representing pain of average severity or the habitual status. The condition on the previous visit served usually as the point of reference in plotting the subsequent course. However, when the visits were more infrequent and the patients seemed uncertain of this point of reference, they were directed to relate the severity of the symptoms to their habitual status. Patients were also directed to consider in their judgment the frequency, the severity and the duration of the pain, and any change that they might have been able to detect in their ability to carry on their usual affairs without pain. The record of each visit included the patient's estimate of the entire period since the last visit and not merely one or two days during the period or the last day of the period.

It was found that, in the initial reply regarding changes in pain, patients often failed to take into account all the necessary factors on which the judgment was to be based, and, not infrequently, more thorough questioning resulted in their revision of their first appraisal. Therein was appreciated an important source of error of another kind; namely, the leading question. Various devices were employed to guard against directing the patient's judgment. Usually they were frankly informed that the examiner was uncertain as to whether the medicine would prove helpful or not, and the idea was conveyed to them that, in any case, subsequent planning for their treatment depended on the accuracy of their statements regarding their condition during the period that had elapsed. In a further attempt to eliminate the possibility of bias, the questioner usually refrained from informing himself as to the agent that had been issued until after the patient's appraisal of the period had been obtained.

The intensity of the pain was graded and charted. Three grades in each direction were considered: increase of pain, slight, moderate or marked; decrease of pain, slight, moderate or marked.

CAUSE AND EFFECT

The plan of the study included a consideration of the manner in which cause and effect were to be established.

Interesting data on this point are provided by the patients themselves. Their statements often represent not only matters of fact but their reflections on causes and effects. Patients were encouraged to disclose their own belief regarding the influence of the drug. Some expressed strong impressions that the agents exerted no beneficial effects, and the lack of disposition on the part of many patients to continue to keep their clinic appointments and to take the medicine regularly may usually be considered as an expression of opinion having a similar significance. Some expressed a definite conviction at times that it was the drug which was responsible for the relief. That that drug was often the lactose placebo, and that some patients insisted on its efficacy, protesting against any suggested change, justifies all the circumspection one can exercise in accepting a patient's judgments in a study of this sort. In some cases this type of questioning served to direct attention to extraneous factors which the patient clearly

perceived as a possible cause of the improvement, such, for example, as a change in the weather or in the amount of work.

The data obtained in this way proved to be entirely unreliable as a basis for establishing the efficacy of theobromine. Several possible causes for change in symptoms, some additive, some antagonistic, practically always coexisted. It seemed futile to attempt to unravel and evaluate the various factors, many of which are unknown, that might be responsible for the relief of pain.

The method we employed for determining cause and effect was more objective and relatively free of personal judgments. The procedure was based on this general formulation; namely, if the relief of pain during the

Chart 1.—Frequency distribution of average systolic and diastolic blood pressures in the 100 cases during the use of a placebo compared with that during treatment with a xanthine.

use of the xanthine is due to the specific action of the drug, the patient should be able to distinguish its effects, and to do so repeatedly, from the effects of a placebo given under similar conditions and in such form as to preclude its detection by the patient through any means other than the relief of pain.

RESULTS

Blood Pressure.—Records of the blood pressure were taken with the mercury manometer at almost every visit throughout the study. Very marked variations, as high as 70 mm. systolic and 30 mm. diastolic, were found in some individuals at different times. The highest and lowest systolic pressures for any individual in a given period were averaged similarly for the diastolic pressures. The averages for the systolic and diastolic pressures in the placebo and xanthine periods are com-

pared in a frequency distribution curve (chart 1). This discloses no significant effect of the xanthine on the blood pressure.

Electrocardiograms were not taken systematically as part of this study. There were several electrocardiograms for each patient, but in only nine cases was a tracing taken during the use of the xanthine. In these, the form of the deflections, their voltage and the time intervals are indistinguishable from those in the patients' control tracing.

Toxic Effects.—Fourteen patients at some time during the study complained of one or more of the following symptoms: dizziness, light-headedness, headache, weakness, nausea, vomiting (in one case) and heartburn. It is not possible to be certain in how many of these cases the symptoms were due to the xanthine. In five cases the symptoms disappeared even though the theobromine was continued in the same or in higher daily doses (from 30 to 60 grains). In three the symp-

The full significance of these observations is not appreciated until one examines the complete record of the various cases. It is not feasible to present a detailed account of all the cases, but several typical cases that have been selected and are shown in charts 2 to 5 will suffice to demonstrate the results, as well as the manner in which the study was pursued to determine whether a patient can identify a xanthine by its influence on cardiac pain from among other agents either inert or known to be of little or no value in this condition.

The records of the hundred cases studied in this way fall into four types:

(a) Those in which the habitual status remained constant and apparently uninfluenced by any drug that was used (8 per cent) (1, chart 2).

(b) Those in which a change of status was always for the worse (12 per cent) (2, chart 2).

(c) Those in which the change of status was always in the direction of improvement (34 per cent) (3, 4 and 5, chart 2; 8, 9 and 11, chart 3; 12, chart 4).

(d) Those in which the condition fluctuated markedly in both directions (45 per cent) (6, 7 and 10, chart 3; 13 to 17, chart 4; 18 and 19, chart 5).

A careful perusal of these records will show that the change in the amount of pain occurring during the use of a xanthine is reproduced by a course of a placebo in every case. It is important to note, however, that there is no dearth of isolated instances which, without further testing, might have led to the impression that the xanthine, by a specific action, had caused improvement.

Some authors⁹ have interpreted the phenomenon as tolerance when a patient ceased to show improvement from a xanthine, and as the absence of cross-tolerance when, by a change to another preparation of a xanthine, the improvement was reestablished. Both of these phenomena are reproduced in our records during the use of a placebo and are therefore probably fortuitous, representing neither tolerance nor absence of cross-tolerance.

TABLE 3.—Changes in Pain During First Course of Treatment

Number of Patients	Theobromine	Placebo
Pain unchanged.....	63	69
Pain diminished.....	22	25
Pain increased.....	15	6
Duration of course.....	1.6 weeks (1-4 weeks)	2.6 weeks (1-8 weeks)

There was one patient (19) who gave strong indication that he was capable, by the relief of pain, of differentiating the xanthine in a variety of forms (tablets and solutions of various colors and tastes) from among a number of other agents. This experiment yielded results that were almost conclusive, but the patient also appeared able to distinguish clearly the taste of the theobromine from that of other agents, even when masked. Before the experiment was carried through to exclude that factor the patient died, and with that there vanished the possibility of conclusive proof in what might have been our only positive case.

COMMENT

Askanazy⁹ appears to have been the first to direct attention to the use of the xanthines in angina pectoris. In the period of about forty years that has elapsed, their use for this purpose has gained momentum and at the present time it is probable that few sufferers with

9. Askanazy, S.: Klinisches über Diuretin, Deutsches Arch. f. Klin. Med. 56: 209, 1895.

Chart 2.—Course in cases 1 to 5. The first column of each chart is made to represent the habitual status of the patient. It is arbitrary, nine squares high, and a column of the same height may refer to pain of different severity in different patients. The periods between individual clinic visits are marked off by the dark lines, or by white lines between black columns. An increase in pain is indicated by an upward direction of the column and a decrease by a downward direction, as follows: slight (change of column by three squares); moderate (change of column by six squares); marked (change of column by eight squares). The solid black columns always indicate a xanthine; it is theobromine, except when labeled A (aminophylline). The dotted columns always indicate a placebo. The cross-hatched columns always indicate active agents and are labeled as follows: S (sodium salicylate), C (calomel), Q (quinidine sulfate), CS (cascara sagrada), Co (codeine sulfate), B (barbital), P (phenobarbital), R (mixture of rhubarb and soda [N. F.]), D (digitalis). Blank columns indicate periods without medicine.

toms disappeared when the doses were reduced from 40 to 20 grains daily. One patient complained of nausea while taking a daily dose of 9 grains of aminophylline.

Effect on Pain.—The effect on cardiac pain of the first course of treatment with the xanthine was compared with that of the first course of a placebo, and the results are given in table 3. As may be seen, most of the patients reported no change, a small number reported that the pain was worse and about one fourth of the patients in each group reported improvement. Of those who reported improvement, eight belonged to both groups.

cardiac pain escape a course of treatment with a xanthine at one time or another.

Numerous reports have been published on the use of these agents for the relief of cardiac pain.¹⁰ These reports do not all show the same degree of optimism. Breuer⁶ declared the introduction of theobromine for the treatment of cardiac asthma and angina pectoris "to be the most praiseworthy therapeutic achievement

When a patient declares that pain has diminished during the use of the xanthine the cause might be the specific action of the drug, but it might also be any one of a number of other factors, such as:

1. Spontaneous variations in the course of the pain.
2. Change in the weather.
3. Change of occupation or amount of work.
4. Change of diet.
5. Change in eating habits with increase in the amount of rest before and after meals.
6. Condition of the bowels.
7. Emotional stress.
8. Change in domestic affairs.
9. Confidence aroused in the treatment.
10. Encouragement afforded by any new procedure.
11. A change of the medical adviser.

Authors have clearly appreciated the numerous sources of error, but they have failed to take many of them sufficiently into account or have minimized their importance in the final evaluation. An interesting example of this is the important study by Gilbert and Kerr.⁵ In their report they referred to angina pectoris as "a symptom complex so readily influenced by nervous factors, and in which there are so many unknown variables," and in regard to treatment they stated: "Reassurance alone is a therapeutic aid of no mean value. Some patients tend to improve from a decrease in emotional strain and from other factors unknown." The regimen in their cases consisted in observation in

Chart 3.—Course in cases 6 to 11.

of the last decade." Gilbert and Kerr⁵ concurred in this statement "with equal emphasis." They reported relief in 83 per cent of a group of eighty-six patients with angina pectoris. On the other hand, Dock¹⁰ observed that "in most cases of angina pectoris no relief was given, but in an important minority relief was immediate and complete." The experience of different observers regarding the time it takes to secure the full therapeutic effects also shows wide divergence. For example, Dock¹⁰ stated that, if decided benefit is not noted within three or four days, further administration is useless. On the other hand, Smith, Rathe and Paul⁷ observed that, in order to insure the maximum benefit from the drug, its administration should be continued for a long time, and Musser¹⁰ found that pain is relieved and the pressure is distinctly lowered "after theophylline-ethylenediamine has been taken for weeks or months."

With one exception,¹¹ the clinical reports have two characteristics in common: first, they all advocate the use of the xanthines and report beneficial results in numbers up to about 80 per cent of the cases in different series; second, they are reports of clinical experience rather than of controlled investigations and represent observations made under conditions that fail to meet essential standards of scientific evidence.

Chart 4.—Course in cases 12 to 17.

the hospital for a few days and the following routine after discharge: regulation of the bowels with liquid petrolatum or three or four glasses of warm water on rising, rest one-half hour before meals and one-half to one hour after meals, withdrawal of "foods which in their experience caused gas," and a dose of a xanthine four times daily. Here, therefore, are five measures, each in itself competent to exert a beneficent influence on cardiac pain, and when in a high proportion of the

eighty-six cases relief was obtained the result was ascribed to the xanthines, without proof that a placebo given under similar conditions would not have accomplished as much.

A word about the experimental basis for the use of the xanthines in the treatment of cardiac pain: Perhaps it is unnecessary to state that the strength of the proof supplied by animal experiments cannot materially enhance the validity of inadequate clinical observations. Clinical reports on the xanthines in cardiac pain lean very heavily on the results of the studies with the isolated heart and in anesthetized animals. These show fairly consistently that the xanthines dilate coronary arteries,¹² and the belief prevails that the soundness of their clinical use is secured in these pharmacologic studies. The indications for the use of the xanthines are, in fact, derived from a combination of current theory as to the mechanism of cardiac pain and the means by which it may be relieved, and dubious inferences from the results of animal experiments; for not one of them is free of objections as a basis for the assumption that the xanthines produce an increase in the capillary or collateral flow through the heart.¹³ The bias created by the undue emphasis placed on the clinical significance of the experimental results is undoubt-

Chart 5.—Course in cases 18 and 19.

edly responsible, at least in part, for the fact that the question whether the xanthines actually relieve cardiac pain in patients with coronary disease has received so little satisfactory independent examination.

Mention has been made of one study in the literature in which exception is taken to the general belief regarding the efficacy of the xanthines in angina pectoris. This is the paper by Evans and Hoyle,¹¹ which appeared while our study was in progress. In that investigation ninety patients were treated with a variety of agents, including xanthines, and their efficacy compared with a placebo. The influence on the pain was determined not only by an estimate of the patient regarding his status but by a written record kept by the patient of the frequency of attacks. As the result of this work they stated that they were unable to convince themselves that the xanthines (as well as the other drugs which they tested) are worthy even of trial in the routine treatment of cardiac pain.

Our study, carried out under substantially similarly controlled conditions, has yielded similar results, and our conclusion is in accord with theirs; namely, that the xanthines exert no specific action that is useful in the routine treatment of cardiac pain.

SUMMARY

1. The effect of theobromine and aminophylline on cardiac pain was studied in a group of 100 ambulant patients with angina pectoris.

2. These patients were selected on the basis of proof of organic heart disease, cardiac pain on effort, little or no physical work, and faithful cooperation.

3. An attempt to include only patients who could distinguish relief afforded by glyceryl trinitrate from relief by a soluble placebo tablet taken in the same way during an attack of pain was abandoned, because a fairly large number of patients with cardiac pain were found who could not distinguish between the two. This is due to the transient character of effort pain in a large proportion of the patients.

4. The effect studied was the influence on the severity and frequency of attacks and on the capacity for effort without pain, not relief during attacks of pain.

5. The data consisted of the patients' judgments regarding changes in pain. These data were secured in a manner relatively free of bias by the use of the "blind test."

6. In all, 209 courses of treatment with the xanthines were given, each course being alternated with a course in which a placebo (or some other agent) was used.

7. The doses of the xanthines were from 15 to 60 grains daily of theobromine, and from 9 to 12 grains daily of aminophylline.

8. Changes in the amount of pain were charted. Cause and effect were established by a method relatively free of personal judgments; namely, by comparing sections of the chart representing periods in which a placebo of lactose (or some other agent) was taken with those in which a xanthine was administered.

9. The xanthines were without appreciable influence on the blood pressure.

10. Every type of change in pain observed during the use of a xanthine was reproduced in the same individual by a period in which a placebo was used.

11. The results show, therefore, that patients with cardiac pain are unable to distinguish the effects of a placebo from those of a xanthine when measures are taken to preclude the identification of the agent by any means other than the relief of pain. It is concluded that the xanthines exert no specific action which is useful in the routine treatment of cardiac pain.

REPORT OF CASES

CASE 1 (F. W., a woman, aged 58).—The diagnosis was arteriosclerosis, hypertension, enlarged heart, coronary thrombosis, regular sinus rhythm, bundle branch block. The habitual status was pain 3+. The duration of study was thirty-seven weeks. The daily dosage of theobromine in order of visits was 15 grains the first week and 30 grains thereafter.

CASE 2 (L. F., a man, aged 41).—The diagnosis was arteriosclerosis, hypertension, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 2+. The duration of study was sixty weeks. The daily dosage of theobromine in order of visits was 30 grains and 15 grains. The daily dosage of aminophylline in order of visits was 12 grains and 9 grains.

CASE 3 (M. A., a man, aged 62).—The diagnosis was arteriosclerosis, coronary sclerosis, sclerosis of the aorta, regular sinus rhythm. The habitual status was pain 2+. The duration of study was fifty-nine weeks. The daily dosage of theobromine in order of visits was 30, 30 and 15 grains.

12. Fowler, W. M.; Hurevitz, H. M., and Smith, F. M.: Effect of Theophylline Ethylenediamine on Experimentally Induced Cardiac Infarction in the Dog. *Arch. Int. Med.* 56:1242 (Dec.) 1935.

Gold, Harry; Travell, J., and Modell, W.: The Effect of Theophylline with Ethylenediamine on the Course of Myocardial Infarction in Experimental Coronary Occlusion, to be published.

CASE 4 (J. G., a man, aged 51).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 1 +. The duration of study was forty-nine weeks. The daily dosage of theobromine in order of visits was 20 grains for the first two and 30 grains thereafter.

CASE 5 (M. S., a man, aged 68).—The diagnosis was arteriosclerosis, hypertension, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was seventy-one weeks. The daily dosage of theobromine in order of visits was 20 grains for the first two and 30 grains thereafter. The daily dosage of aminophylline in order of visits was 12, 12 and 6 grains.

CASE 6 (M. C., a man, aged 61).—The diagnosis was arteriosclerosis, enlarged heart, coronary sclerosis, regular sinus rhythm, bundle branch block. The habitual status was pain 3 +. The duration of study was eighty-three weeks. The daily dosage of theobromine in order of visits was 20 grains for the first week and 30 grains thereafter.

CASE 7 (A. B., a man, aged 60).—The diagnosis was arteriosclerosis, enlarged heart, coronary sclerosis, regular sinus rhythm. The habitual status was pain 2 +. The duration of study was eighty-eight weeks. The daily dosage of theobromine in order of visits was 20, 20, 30 and 30 grains.

CASE 8 (S. K., a man, aged 70).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was seventy-two weeks. The daily dosage of theobromine in order of visits was 30, 30 and 45 grains.

CASE 9 (A. K., a man, aged 53).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was seventy-six weeks. The daily dosage of theobromine in order of visits was 20 grains for the first five and 40, 40, 60, 60 and 15 grains thereafter.

CASE 10 (A. N., a man, aged 62).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, sclerosis of the aorta, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was seventy-two weeks. The daily dosage of theobromine in order of visits was 20 grains. The daily dosage of aminophylline in order of visits was 12 and 9 grains.

CASE 11 (F. B., a man, aged 65).—The diagnosis was arteriosclerosis, hypertension, coronary sclerosis, aortic sclerosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was fifty-four weeks. The daily dosage of theobromine in order of visits was 30, 30 and 30 grains. The daily dosage of aminophylline in order of visits was 12 and 9 grains.

CASE 12 (G. S., a woman, aged 56).—The diagnosis was arteriosclerosis, hypertension, enlarged heart, sclerosis of the aorta, regular sinus rhythm. The habitual status was pain 1 +. The duration of study was seventy-one weeks. The daily dosage of theobromine in order of visits was 15, 20 and 20 grains.

CASE 13 (H. R., a man, aged 55).—The diagnosis was arteriosclerosis, hypertension, enlarged heart, coronary thrombosis, sclerosis of the aorta, regular sinus rhythm. The habitual status was pain 2 +. The duration of study was seventy-four weeks. The daily dosage of theobromine in order of visits was 20, 30, 30 and 40 grains.

CASE 14 (J. C., a man, aged 40).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm with premature contractions. The habitual status was pain 2 +. The duration of study was seventy-six weeks. The daily dosage of theobromine in order of visits was 30, 30 and 30 grains.

CASE 15 (S. O., a man, aged 55).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was sixty-four weeks. The daily dosage of theobromine in order of visits was 15, 30, 30, 20, 40 and 20 grains.

CASE 16 (L. L., a man, aged 44).—The diagnosis was arteriosclerosis, enlarged heart, coronary sclerosis, sclerosis of the aorta, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was fifty-six weeks. The daily dosage

of theobromine in order of visits was 20, 15, 30 and 20 grains. The daily dosage of aminophylline in order of visits was 12, 12 and 12 grains.

CASE 17 (S. N., a man, aged 53).—The diagnosis was arteriosclerosis (diabetes) enlarged heart, coronary thrombosis, aortic sclerosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was seventy weeks. The daily dosage of theobromine in order of visits was 20, 40, 40, 30, 40, 30 and 15 grains.

CASE 18 (M. G., a man, aged 56).—The diagnosis was arteriosclerosis, enlarged heart, coronary thrombosis, regular sinus rhythm. The habitual status was pain 3 +. The duration of study was 120 weeks. The doses of theobromine in order of visits were 20, 40, 20, 30, 15, 15, 30, 30 and 40 grains.

CASE 19 (C. E., a man, aged 68).—The diagnosis was arteriosclerosis, enlarged heart, coronary sclerosis, regular sinus rhythm with ventricular premature contractions. The habitual status was pain 3 +. The duration of study was ninety-seven weeks. The doses of theobromine in order of visits were 30 grains for the first four visits; 25, 15, 30, 15 and 30 grains; the following twelve visits, 15 grains.

TECHNICAL FACTORS AFFECTING THE TUBERCULIN TEST

WALDO E. NELSON, M.D.

CINCINNATI

FLORENCE B. SEIBERT, PH.D.

AND

ESMOND R. LONG, M.D.

PHILADELPHIA

It has been known for some time that tuberculin is extremely heat resistant and that it adheres to glass and other materials after they have been washed and sterilized. Attention has been called to this fact by such workers as Zieler,¹ Smith,² Parish and O'Brien³ and Schick,⁴ and similar facts have been demonstrated for other allergens by Rackemann and Simon.⁵ Krause,⁶ in recalling experiments performed some years ago, has recently called attention to the precautions necessary to secure trustworthy results in immunologic experiments with extracts of tubercle bacilli. We have ourselves repeatedly secured positive reactions in tuberculin-hypersensitive persons when only physiologic solution of sodium chloride (0.85 per cent) was used in syringes previously employed for tuberculin, although these syringes had been washed and boiled and autoclaved. However, it has become increasingly evident to our two groups that insufficient attention is paid to this factor, and we have therefore decided to present jointly further data bearing on this subject.

The danger from such contamination may be illustrated by the following incident: A young physician whose Schick test had been negative several months previously stated that he was now Schick positive. On questioning it was discovered that the Schick test had been made with a syringe previously employed for

tuberculin. Separate Schick and tuberculin tests were performed with new (previously unused) syringes, and it was demonstrated that he had a positive tuberculin reaction and a negative Schick test.

Following this, simultaneous Schick tests were performed on 125 children with a new syringe for the test on one arm and a syringe previously used for tuberculin and then washed and sterilized on the other arm.

TABLE 1.—Simultaneous Schick Tests with a New Syringe and with a Syringe Which Had Been Previously Used for Tuberculin, Cleaned and Sterilized

92†	..	14	3

* From the Children's Convalescent Home of Cincinnati. Syringe autoclaved.

† From the Preventorium of the Hamilton County Tuberculosis Sanatorium. Syringes boiled. Tests performed by Dr. Helen Mabon.

‡ Seven of these gave a 50 per cent greater reaction with the contaminated syringe than with the new syringe, indicating that part of the reactions have been due to tuberculin. None showed the reverse order of reaction.

In seven instances the test was positive in the arm on which the toxin from the syringe previously used for tuberculin was used, while negative in the other arm on which the same amount of toxin was used from a new syringe. The patients injected were tuberculin positive, and these seven reactions must be looked on as falsely positive Schick tests, in reality tuberculin reactions (table 1).

Other incidents have demonstrated that tuberculin may be transferred by articles other than syringes and that rigid technic is necessary to avoid such contamination. An experiment, initiated at the Henry Phipps Institute primarily for the purpose of determining whether nonspecific reactions may occur from the intracutaneous injection of physiologic solution of sodium chloride (0.85 per cent) containing 0.5 per cent phenol, furnished an excellent example of the marked potency of infinitesimal amounts of tuberculin, the presence of which may be entirely unsuspected. In these tests a new syringe was employed, but it was discovered finally that the bottles had been filled with the various diluent solutions from a pipet that had been used previously for tuberculin and then washed and sterilized in the usual manner (tests 1, 2 and 3 in table 2). The seemingly inconsistent results obtained in these three tests, namely, that the largest percentage of reactions occurred with the "buffer diluent" alone and less with the "buffer diluent + 0.25 per cent phenol" and with the "buffer diluent + 0.5 per cent phenol" are probably explained by the fact that this was the order in which the solutions were pipetted into the bottles. Another means of contaminating nontuberculin solutions with tuberculin is illustrated in tests 4 and 5 in table 2. In these instances bottles of diluent were covered with rubber caps that had been employed previously to stopper tuberculin vials and then cleaned and sterilized. Sufficient tuberculin adhered to the rubber cap to "contaminate" the diluent and produce positive tuberculin reactions in persons hypersensitive to tuberculin.

Examination of the data included in table 2 reveals that reactions to "contaminated diluent" occurred only in those persons who had positive reactions to tuber-

culin. For this reason further tests were performed with buffered diluent and with physiologic solution of sodium chloride, both with and without 0.25 per cent and 0.5 per cent phenol. Care was taken to use new glassware, rubber and needles. Positive reactions were not obtained from the use of any of these solutions in either positive or negative tuberculin reactors. It seems clear that, with the ordinary method of cleaning, small amounts of tuberculin may remain adherent to glass and rubber, and probably to other materials, in sufficient amounts to produce a positive tuberculin reaction in persons hypersensitive to tuberculin.

METHODS OF CLEANING SYRINGES

A desire to clean syringes adequately naturally leads to the use of alkali, since this was found to be the best solvent for the tuberculin protein and its fractions during their isolation. Accordingly, a syringe that had been used for tuberculin tests for some time was rinsed with 5 per cent sodium hydroxide solution, subsequently with water, and then sterilized. It was filled with the "buffer diluent + 0.25 per cent phenol" that had been shown to give no reactions and, as noted in table 3, test 1, positive reactions were obtained in some reactors to tuberculin (purified protein derivative [P. P. D.]), indicating that this method of cleaning the syringe was inadequate. Another syringe previously employed for tuberculin was immersed in 5 per cent sodium hydroxide

TABLE 2.—Contamination of Diluting Solutions with Tuberculin by Syringes, Pipets and Rubber Caps; Effect of 0.5 per Cent Phenol in Skin Testing Solutions

Test	Description of Test	Number of Tests	Number Positive to Tuberculin (P.P.D.)	Number Positive to Diluent Among

over night, rinsed many times with water, sterilized and then filled with "buffer diluent + 0.5 per cent phenol," also shown previously to produce no reactions. Three reactions occurred in nineteen positive reactors (test 3, table 3) to the purified protein derivative, indicating again that this method is not satisfactory for cleaning syringes.

The efficacy of cleaning tuberculin syringes with sulfuric acid-dichromate cleaning mixture and by boiling in soap solution has also been tested. Eight simultaneous tests in tuberculin-positive children were performed with known tuberculin-free physiologic solution of sodium chloride. The syringes employed had previously been used for tuberculin and treated as shown in tests 3 to 8, inclusive, in table 3. Positive reactions were obtained with solutions from the syringes that were simply washed and sterilized or even heated for ten minutes in cleaning mixture. However, the syringes seem to have been cleaned adequately if immersed for twelve hours or more in cleaning mixture or boiled in soap solution for ten minutes.

Since, however, such unusual measures are necessary to make certain that syringes previously used for tuberculin are, after cleaning, free from tuberculin particles, it would seem best to keep separate syringes for tuberculin and other types of skin testing solutions.

THE EFFECT OF 0.5 PER CENT PHENOL IN SKIN-TESTING SOLUTIONS ON THE SKIN REACTION

The experiment (tests 1, 2 and 3, in table 2) originally designed to determine whether 0.5 per cent phenol was capable of producing a skin reaction was repeated. New glassware was used throughout in the preparation and injection of the solutions. Buffered diluents and physiologic solutions of sodium chloride were prepared with 0.25 per cent phenol and with 0.5 per cent phenol (tests 7 to 12, inclusive, table 2). No reactions were obtained to any of these solutions with the exception of an occasional papule 2 or 3 mm. in diameter. Such reactions were as frequent with the physiologic solution of sodium chloride as with the 0.5 per cent phenol and were thought to be due to trauma. Furthermore, five persons having 4 plus or severe 3 plus reactions with tuberculin and at the same time small reactions in the other arm with a buffer diluent containing 0.25 per cent phenol given from a syringe previously used for tuberculin were retested one week later with the control solution. This time a new syringe and needle were used and no reactions occurred. In order to ascertain whether free alcohol on the injected surface might increase the likelihood of nonspecific small reactions, simultaneous tests were performed with physiologic solution of sodium chloride and with physiologic solution of sodium chloride + 0.5 per cent phenol on dry skin surfaces and on skin wet with alcohol. Fifteen children thus received sixty tests. In only one instance was there any reaction after forty-eight hours. This was a papule 2 mm. in diameter from a test with physiologic solution of sodium chloride + 0.5 per cent phenol on a dry arm.

CONFUSION OF THE TERMS PHYSIOLOGIC AND NORMAL SALT SOLUTION

A curious accident indicates the possibility of an unusual source of error. While the experiments described here were in progress, "normal saline" was ordered from the preparation room. There was supplied, however, normal, i. e., molar NaCl (5.8 per cent). This, according to instructions, was put up with and without phenol. All the children tested with these solutions had small reactions with marked redness and slight edema, and twenty-five of thirty-three children who were tested with the hypertonic salt solution + 0.5 per cent phenol had reactions with areas of central necrosis. None of these reactions were larger than 8 mm. in diameter. Similar reactions to hypertonic salt

solutions were observed by one of us (F. B. S.⁷) in animals in the early work of crystallizing tuberculin protein. Such small amounts of crystalline protein were obtained at that time that it was impossible to remove all the ammonium sulfate from the preparations before testing. It was, however, possible to distinguish the salt reactions of marked necrosis from the true tuberculin reaction with much edema.

Although the term "normal saline" is rather widely employed to designate physiologic solution of sodium chloride, it would seem safer to use the term "physiologic" or, even better, to specify the percentage of NaCl.

SUMMARY AND CONCLUSIONS

Evidence is presented on the heat stability of tuberculin and the tendency of tuberculin to remain adherent to glassware and rubber. A certain proportion of tuberculin-positive subjects react to the injection of physiologic solution of sodium chloride from syringes previously used for tuberculin and then simply washed and sterilized. The use of pipets and rubber stoppers, previously employed for tuberculin and subsequently

cleaned by ordinary methods, may introduce into supposedly tuberculin-free mediums sufficient tuberculin to produce occasional reactions.

The clinical importance of these facts is apparent. When Schick tests were made with syringes previously used for tuberculin and cleaned by ordinary methods, falsely positive Schick tests, in reality tuberculin reactions, were often obtained. The danger in the employment of tuberculin syringes in routine allergy tests, as with pollen proteins, is also apparent.

Phenol in concentrations of 0.25 and 0.5 per cent in physiologic solution of sodium chloride does not cause a reaction simulating the tuberculin reaction.

The most effective methods of cleaning syringes to destroy all traces of tuberculin are boiling in soap solution and prolonged immersion in sulfuric acid-potassium dichromate cleaning fluid. It is probably safer and more practical, however, to use syringes never before used for tuberculin whenever a tuberculin reaction might confuse the result, as in the Schick test or in various protein allergy tests.

The increasing number of inquiries coming from physicians in various sections of the country makes it desirable to publish at this time a note on the results of recent work on chemoprophylaxis in experimental poliomyelitis and to suggest a procedure which may hold something of practical value in controlling the spread of this disease in man during epidemic periods.

The more fundamental aspects of the disease which initiated these studies have been summarized by one of us in an earlier article in *THE JOURNAL*.¹ The chief facts that need to be carried in mind to follow the logic of this new approach are briefly as follows:

1. The disease is caused by a highly neurotropic virus, which in size is among the smallest of known ultramicroscopic viruses.²

2. In monkeys, and probably in man also, the virus reaches the central nervous system by way of the olfactory nerve. Complete section of both olfactory tracts in monkeys definitely prevents invasion of the central nervous system by virus subsequently instilled intranasally.³

3. Virus reaching any part of the nervous system, either peripheral or central, travels by axonal paths, probably largely or entirely inside the protoplasmic substance of neurons. This conclusion is supported by the effect of sectioning nerve paths,⁴ by the results of sampling different parts of the nervous system during various stages of the infection,⁵ by the appearance of intranuclear inclusion bodies in some of the nerve cells⁶ and by the fact that nerve cell degeneration is primary and largely independent of the inflammatory reactions seen in the fully developed disease.⁷ It is supported also by observations which indicate that immune serum is not effective in reducing the severity of the experimental disease in monkeys, and this even when the serum is administered several days before the onset of

symptoms.⁸ The results of more critical studies on the value of serum therapy in the human disease are in harmony with these observations in animals.⁹

4. So far as is known, the actual portal of entry, which in general is through the olfactory area, may be either the olfactory hairs, the "olfactory cells" (cell bodies of the first neurons), which lie quite superficially in the olfactory mucosa, or the perineural spaces of the olfactory nerves, or some combinations of these. Whichever of these it may be, it is quite clear from recent experimental studies that immune serum even in very large doses is not significantly effective in preventing infection with virus which is subsequently administered by the nasal route.¹⁰ This suggests that it is not necessary for the virus to pass a barrier of immune serum to reach its destination in the central nervous system.

5. Vaccines also have not proved significantly effective in establishing resistance against infection by the intranasal route.¹¹ The action of vaccines, even of living vaccines, seems to be limited largely or entirely to the stimulation of antibody formation, but, as has already been pointed out, humoral antibodies do not in themselves provide an effective barrier against either invasion or the subsequent dissemination of the virus in the nervous system. When a nonliving (inactivated) vaccine is used even the stimulus to antibody formation tends to drop out of the picture.

6. Acquired active immunity to this disease seems to depend primarily on some kind of modification of the protoplasm of the nerve cell, a modification which is brought about only by intimate contact of the cell with the virus.¹² However, thus far no method has been found which, in monkeys at least, will provide this intimate contact without also producing paralysis.

7. Although naturally acquired active immunity to poliomyelitis is generally associated with humoral antibodies, these seem to constitute merely an adventitious by-product of the infection and are probably largely the result of a reaction to virus which has left its natural nervous channels and come in contact with the antibody-producing mechanism of the body.¹³

8. Many normal adults without knowledge of a previous exposure to poliomyelitis show antibodies for the virus in their blood, and this sometimes in high concentrations,^{13b} but if the presence of such antibodies in normal persons is always associated with an acquired active immunity to this disease, which appears not to be true,¹⁴ they should probably be regarded as merely indicators of an earlier infection and not so much as active participants in the state of resistance.

In short, a fuller understanding of the pathogenesis of this disease has not only served to explain the uncertain results that have been obtained with serums and vaccines but left the profession also with comparatively little hope of controlling the disease by such orthodox means. The present status of our knowledge of this disease, therefore, indicates that the only real hope of bringing it under control lies in modifying the normal portal of entrance by some measure which will insure at least temporary protection to the susceptible individual.

The idea that certain chemicals applied to the olfactory mucosa might in some way modify its permeability to the virus seems to have occurred to three independent groups of workers about the same time. In May 1935 Armstrong and Harrison¹⁵ of the National Institute of Health in Washington reported that monkeys treated intranasally with a 4 per cent sodium aluminum sulfate (alum) solution exhibited a high incidence of resistance to subsequent intranasal instillation of virus. Some months later, Sabin, Olitsky and Cox¹⁶ of the Rockefeller Institute confirmed these observations and reported that 4 per cent tannic acid also exercises a protective action. Early in 1935, after making a study of the value of serums and vaccines in preventing the experimental disease and having before us earlier observations which indicated that preliminary intranasal irrigation with phosphate buffer solutions of different p_H influences differently experimental infection by the intranasal route,¹⁷ we began carrying out a few small experiments to elicit whether some degree of protection might be obtained against this disease by means of chemicals that might in some way decrease the permeability of the olfactory area. The results of initial tests in which we used tannic acid did not appear especially encouraging, and so we turned our attention to other agents, among them trinitrophenol (picric acid), paranitrophenol, trinitrocresol and mercurochrome, which we thought might modify the portal by their staining or some other local action. All those mentioned were found to exercise a definite protective action, but what came as a great surprise to us was the duration of the resistance induced by at least one of these agents. Feb. 5, 1936, we reported¹⁸ to the Pacific Coast Section of the Society for Experimental Biology and Medicine the important fact that monkeys given several successive daily intranasal washes with picric acid may without further treatment remain resistant to repeated instillations of virus for more than a month. Several weeks later (February 28) a paper by Armstrong and Harrison¹⁹ appeared, also testifying to the protective action of picric acid. Their results were in all essentials like ours except that they did not determine the duration of the protection that the picric acid had afforded.

Thus far we have tested the protective value of forty chemical agents. We undertook to test this many in

order to determine as fully as possible the range of substances which may convey a more or less well defined protection against subsequent intranasal instillations of virus in monkeys. The results will be published in full later. In this paper we wish merely to announce that out of the array of substances which we have tested there is one, namely, zinc sulfate, which because of its simple composition, relatively low toxicity and surprisingly high protective action in monkeys seems to deserve a trial in man. Because of the remarkably uniform results obtained in our initial experiments we proceeded to make a more exhaustive study of this agent than we have of the others. More than 240 animals have now been treated intranasally with different concentrations of zinc sulfate in solution, administered a varying number of times and at different intervals of time, and the resistance of these test animals has been compared with a total of nearly 300 untreated controls.

We may summarize the results very briefly by saying that two or three successive daily intranasal sprays with a 1 per cent solution of zinc sulfate in physiologic solution of sodium chloride (0.9 per cent NaCl) will generally protect all, or nearly all, of the animals so treated against virus administered one month after the treatments have been applied. This degree of protection is exhibited under sufficiently heavy instillations of virus to bring down about 90 per cent of the controls. Zinc sulfate affords not only a higher percentage of protection in monkeys than picric acid, or picric-alum in equivalent concentrations, but also a more lasting resistance.²⁰ Many of our treated animals have survived repeated virus instillations for two and even three months, following one or more intranasal applications of the zinc sulfate solution. In an experiment now in progress, twelve monkeys were each given one intranasal spray with a 1 per cent solution of zinc sulfate in physiologic solution of sodium chloride. Virus instillations were begun a week later and have been kept up on five successive days each week for seven weeks to date; two additional sprays with zinc sulfate two weeks and four weeks, respectively, after the first treatment have punctuated these virus instillations, the latter being continued without further treatment twenty-seven days after the last spraying with zinc sulfate. Thus far, only two of the animals have succumbed to poliomyelitis, while the disease has developed in all of the eleven controls with which we started the experiment. In another experiment, in which eight monkeys were given a single intranasal spray with a solution containing 1 per cent zinc sulfate and a local anesthetic of 0.5 per cent pontocaine²¹ (para-butylaminobenzoyldimethylaminoethanol hydrochloride) and without further treatment were given seven virus instillations from twenty-five to thirty-two days later, seven survived the virus instillations, while all of the eight controls became infected.

The remarkable protection yielded by this simple and relatively nontoxic agent in animals suggests the desirability of carrying the investigation over to man. We say "investigation" advisedly, for it does not necessarily follow that the results which have been obtained in monkeys apply equally in man. Therefore, with the most important question still to be answered—that of its effectiveness in man—there must be no relaxation of the principles that must guide a research in carrying

the investigation over to man, for, unless great care is exercised, no really helpful information will be likely to come out of such further work. In a critical review of the application of picric-alum solution in Alabama last summer, Armstrong²² points out the pitfalls that beset a satisfactory field test. The observations that he presents in this paper make it very clear that the application of a prophylactic measure such as this must be kept entirely in the hands of those who are fully competent to apply it properly. It is not a prophylactic measure which can be turned over to the public for self administration. It is already known that in order to be effective the agent must be actually applied to the olfactory mucosa and that adequate coverage of this area is not assured by self administration with an ordinary hand atomizer.

With these considerations in mind, we would suggest the following procedure in carrying this investigation over to man:

1. The use of a solution containing 1 per cent zinc sulfate, 0.5 per cent sodium chloride and 1 per cent local anesthetic (pontocaine) as suggested.

2. The solution should be prepared with U. S. P. zinc sulfate, U. S. P. sodium chloride and distilled water.

3. It should be applied at least once every two weeks during times when the risk of infection is great. A more desirable procedure would be to apply the agent on two or three successive days and once every two weeks thereafter. The latter would naturally prove more difficult to carry out in actual practice.

4. It should be applied with an atomizer equipped with a suitable tip and in accordance with the technic described by Dr. Max Peet in this issue of THE JOURNAL.²³

5. Since the zinc sulfate solution thoroughly applied in this manner may be somewhat painful, Dr. Peet suggested several months ago that we determine whether the addition of 0.5 per cent pontocaine to the zinc sulfate solution detracts in any way from its protective action. From the results of tests on thirty-two monkeys treated with a solution containing 1 per cent zinc sulfate and 0.5 per cent pontocaine we can say definitely that pontocaine in no way detracts from the protective action of the zinc sulfate. The influence of other local anesthetics on the prophylactic action of this agent are now being studied by us.

6. The prophylactic zinc sulfate mixture should be administered under the auspices and supervision of national, state or local health organizations, aided by members of the medical profession who have been instructed in the special technic that should be followed. This calls for some previous organization of local health forces.

7. A record should be kept in the local health office of all persons treated. These should bear the name, age, address of the person treated, dates of all treatments and a notation of any anatomic conditions in the nasal passages which may have interfered with a satisfactory application of the solution. The general health of the individual should also be noted.

8. Those who supervise the treatments should be alert to any possible side actions or important harmful local or general effects. While we have not observed any noteworthy gross or microscopic changes in the nasal mucous membranes of monkeys treated repeat-

edly with zinc sulfate other than a mild grade of inflammation, such as may be seen at times even in untreated monkeys, it nevertheless seems important to suggest alertness to any effects which may contraindicate the general use of this agent or agents if pontocaine is included in the solution. Although there is no good reason to believe that zinc sulfate, in the small amounts required to cover the olfactory area, would produce any undesirable or harmful effects, either local or general, idiosyncrasies should be kept in mind.

9. Any objectionable or undesirable effects from the treatment should be reported to the local health officer, who should enter the information on the card and take such steps as may seem desirable.

10. In measuring the results later, only those persons who have received adequate treatments under competent supervision and for whom there is a record of treatment on file should be considered as having received valid treatments. Claims of self administration of the solution should not be regarded as valid.

The first practical human application of any such laboratory observation as this must of necessity be in the nature of an investigation, and unless this part of the work is carried out with care it is unlikely that any significant additional information will be obtained from such field application. While further laboratory studies may in time lead to a more satisfactory procedure, the immediate task before the profession is to make the best possible use of the most promising practical measure now available for the control of this disease.

THE CHEMICAL PROPHYLAXIS FOR POLIOMYELITIS

THE TECHNIC OF APPLYING ZINC SULFATE INTRANASALLY

MAX M. PEET, M.D.

DEAN H. ECHOLS, M.D.

AND

HARRY J. RICHTER, M.D.

ANN ARBOR, MICH.

The recent discovery that certain chemicals applied to the olfactory area of the nose in monkeys gives a temporary immunity against subsequent instillations of an active poliomyelitis virus is the first definite evidence that this disease can be prevented and offers the hope that similar prophylactic treatment in children will likewise protect them. In 1935 Armstrong and Harrison¹ of the United States Public Health Service reported that monkeys could be protected against intranasal inoculations of poliomyelitis virus by previous douching of the nose with solutions of alum, trinitrophenol (picric acid) or a combination of the two. A rather extensive field application of this type of prevention² was made in the summer of 1936, but the nasal spray applications were generally carried out in such a manner as to indicate, in the light of later work, that the majority of the children received no protection.

From the Division of Neurosurgery and the Department of Otolaryngology, University of Michigan Medical School.

The investigation on which this report is based was made possible by a grant from the President's Birthday Ball Commission for Infantile Paralysis Research.

23. Peet, M. M.; Echols, D. H., and Richter, H. J.: The Chemical Prophylaxis for Poliomyelitis: The Technic of Applying Zinc Sulfate Intranassally, this issue, p. 2184.

In 1936 Schultz and Gebhardt³ showed that a solution of zinc sulfate gave a more lasting and a higher degree of protection than any other chemical of a long list, including alum and picric acid. The demonstration by Schultz and Gebhardt⁴ that a single spraying of 1 per cent zinc sulfate protects an animal for at least three weeks against repeated intranasal instillations of an active virus increased the practicability of applying chemical prophylaxis to human beings.

This experimental work of Armstrong and Schultz now offers the first definite hope of controlling infantile paralysis, since the various vaccines that were advocated as protection in human beings have completely failed to protect monkeys against an intranasal inoculation of the virus. Extensive research work has shown that the virus probably enters the body only through the olfactory nerves.⁵ Intracranial division of these nerves completely protects the monkeys against subsequent intranasal inoculations of the virus. This demonstration that the virus enters only through the olfactory nerves, combined with the proof that a 1 per cent zinc sulfate solution so modifies the portal of entry that the virus cannot pass, provides a definite lead for extensive field trials in the prevention of poliomyelitis in children.

Several questions are immediately presented: First, will zinc sulfate be as effective in protecting human beings as monkeys? This can be determined only by actual clinical use during an epidemic. Second, will the application of this prophylactic measure be free from danger? Zinc is a harmless metal, and authorities agree that there is no evidence of the existence of chronic zinc poisoning. Zinc sulfate has long been used in diseases of the eye and nose without a single instance of serious harm resulting. With such a weak solution as 1 per cent, the strength recommended for nasal instillation, and in the small quantity used, we feel certain that no serious sequelae will result. However, it was found that when zinc sulfate was actually applied to the olfactory area^{6,7}, produced a severe burning or smarting sensation with coryza and in most subjects a severe headache, which lasted for several hours. Zinc sulfate introduced into the lower portion of the nose does not produce such symptoms. It is only when it is applied to the olfactory area that this pain results. While the probable protection afforded would justify this discomfort, it was felt advisable to eliminate the pain as much as possible. It was found that the local anesthetic pontocaine hydrochloride, added to the zinc sulfate solution, would minimize and in many cases completely eliminate the discomfort that follows high nasal instillations of 1 per cent zinc sulfate alone. Various percentages of the local anesthetic were tried. Five-tenths per cent pontocaine gave considerable relief, but a 1 per cent solution was much more effective, and in twenty of a group of twenty-five subjects little or no real discomfort was noted. However, a few adults complained of a dull headache of from one to several hours' duration after the immediate effect of the anesthetic had disappeared. Children were less adversely affected by the zinc sulfate, and in none of the children tested was headache noted when the 1 per cent panto-

caine was added to the spray. The burning or smarting sensation felt immediately after the instillation of 1 per cent zinc sulfate without pontocaine was not observed when the local anesthetic was used.

A careful review of the literature fails to disclose any instance of pontocaine poisoning. The probabilities are that in a very wide application of this treatment individuals may be found who do have an idiosyncrasy to this anesthetic. However, even in susceptible persons one would not expect serious reactions, since the anesthetic is applied only on the surface, in a dilute solution, and in a total quantity of not more than 2 cc. The local anesthetic could, of course, be applied to the olfactory area as a surface spray before the application of the zinc sulfate. Such a procedure is no more effective and has certain disadvantages, especially in an extensive field application such as would be necessary in a threatened epidemic. Two intranasal applications would require double the time for their administration and certainly in small children it would be much simpler to get cooperation for a single spraying than for two. We therefore advise the use of a solution

Fig. 1.—The type of atomizer recommended for spraying the roof of the nose.

containing 1 per cent zinc sulfate, 1 per cent pontocaine hydrochloride and 0.5 per cent sodium chloride (to make the solution more nearly isotonic).

The question naturally arises Does the zinc sulfate and pontocaine mixture have any harmful effect on the olfactory nerves? Careful investigation of this problem has been undertaken. A group of medical students were carefully tested by Elsberg's⁸ method of quantitative olfactometry before and after the zinc sulfate spray or the zinc sulfate and pontocaine spray had been applied to the olfactory area. When the solution has been properly applied to the upper nasal mucous membrane the sense of smell is temporarily lost, or at least impaired, but always returns to normal in a week to two weeks. The rapidity of recovery is dependent on the number of consecutive days the zinc sulfate has been used.⁷

The actual application of the zinc sulfate solution to the olfactory area has been found more difficult than was anticipated. It is apparently much simpler to cover the olfactory area in monkeys than in human beings. This we have demonstrated by spraying both monkeys and children with radiopaque substances such as skiodan and thorium dioxide sol,⁸ using an ordinary atom-

8. Because of the radioactivity of thorium dioxide sol we did not use children who had a life expectancy of more than one year.

izer. With the monkeys' heads tilted slightly backward, the olfactory area was thoroughly covered. However, in children, the radiopaque material did not regularly reach the cribriform plate when applied in an identical manner. With the patient held in the Proetz position (patient on the back with the head hanging over the edge of the table) thorium dioxide sol sprayed by the

Fig. 2.—Proper application of the spray.

ordinary method would reach the olfactory area in some children but in many others it would not. Shrinkage of the nasal mucous membrane preliminary to spraying did not always aid in reaching the olfactory area. Direct nasal examination after spraying a large number of children with methylene blue showed that in practically all instances the solution did not go above the middle turbinate if an ordinary atomizer was used with the tip of the spray introduced only slightly within the nostril. It was this type of spraying that was used extensively during the summer of 1936 in Alabama, and we now feel convinced that a large proportion of the children did not receive adequate prophylactic treatment. From our experiments in which radiopaque substances and certain dyes were used, it is evident that the spray must be applied directly to the olfactory area. Such application can be made under direct vision with an atomizer⁹ with a long, narrow metal tip (fig. 1).

Nasal douching with the head in the Proetz position might be as effective in some children as a properly applied spray. However, it would require larger quantities of the solution with the probability that some of the anesthetic would enter the accessory sinuses and pharynx with the possibility that the cough reflex might be abolished, thus predisposing to pneumonia. The Proetz position with instillation of zinc sulfate by dropper may of necessity be used when small children are so uncooperative that insertion of the nasal spray tip is impossible. Under these circumstances the pontocaine should be omitted. The child should be kept in the head-down position for about two minutes.

We recommend the following method of application: The subject is seated and an attendant holds the head tilted backward about 45 degrees (fig. 2). This is the usual position for a nasal examination. A speculum

is introduced into the naris and under direct vision the spray tip is inserted upward along the septum until definitely past the middle turbinate (fig. 3). If it impinges on the roof of the nose it is slightly withdrawn. The bulb is squeezed the number of times required to introduce 1 cc. of solution. This amount, according to our x-ray and necropsy evidence, completely covers the olfactory area. A similar procedure is then carried out on the opposite side of the nose. Loss of the olfactory sense is thus obtained.

Only slight discomfort is felt when the spray tip is passed through the narrow cleft between the middle turbinate and the septum or when it touches the roof of the nose. If the nasal passage is found occluded on direct inspection the nasal mucous membrane should be shrunk by the application of ephedrine or benzedrine inhalant preliminary to the insertion of the spray tip. A power sprayer can be used instead of the hand bulb but should not deliver more than a few pounds of pressure. The quantity delivered by the power sprayer should be definitely determined and not more than 1 cc. of the solution introduced into each side of the nose.

According to the experimental work of Schultz, a single spray of zinc sulfate and pontocaine is sufficient to protect animals for at least two weeks. However, in our experiments on man we have repeated this spray for three successive days. Such intensive spraying, while perhaps not necessary, does give greater assurance of complete coverage, since on the first application of the spray there may be small areas covered by tenacious secretions which conceivably would not be present on the same areas on succeeding days. Possibly in an extensive field application of the zinc sulfate for the prevention of poliomyelitis a single spray repeated at intervals of two weeks would be sufficient; however, we recommend daily spraying for three consecutive days, then single sprays at intervals of two weeks.

It is evident that to be effective the spray must be directly applied to the olfactory area. We wish especially to emphasize this point. Ordinary spraying with

Fig. 3.—Tip of atomizer in proper position.

the atomizer tip introduced below the middle turbinate will not suffice except in isolated instances. Therefore, to offer a child the only protection now known for the prevention of infantile paralysis, the spray solution must be actually applied to the olfactory area, and this can be accomplished only under direct observation with proper equipment and by one trained in this particular

9. The spray used in this work was a DeVilbiss Atomizer No. 156 with spray tip No. 156 N. C.

technic. It is not a procedure which can be applied by the parents or by a physician not familiar with intranasal work.

SUMMARY

The definite proof that a 1 per cent zinc sulfate solution applied to the olfactory area affords a high degree of protection against intranasal instillations of active poliomyelitis virus in monkeys offers definite hope that a similar application will protect human beings from this disease. The actual proof, however, can be determined only by an extensive field trial in the presence of a threatened epidemic.

A 1 per cent zinc sulfate solution can be safely applied to the olfactory area but if used alone produces varying degrees of discomfort, such as burning or smarting in the nose, coryza and more or less severe headache lasting sometimes for several hours. The addition of a local anesthetic such as pontocaine will largely relieve this discomfort. The spray solution recommended is 1 per cent zinc sulfate, 1 per cent pontocaine and 0.5 per cent sodium chloride. This must be applied directly to the olfactory area.

The use of an atomizer with the ordinary tip introduced into the naris is of no value, since in the majority of cases the spray does not pass upward beyond the middle turbinate. A special spray tip must be introduced to the region of the cribriform plate under direct vision. At least 1 cc. of solution should be sprayed over each olfactory area. This procedure can be carried out effectively only by one trained in its technic.

AN ERYSIPELAS-LIKE ERUPTION COMPLICATING DERMATO- PHYTOSIS

EUGENE F. TRAUB, M.D.

AND

JESSE A. TOLMACH, M.D.

NEW YORK

The increased amount of attention focused on fungous infections in recent years has given rise to an ever greater number of new studies and observations. It has been interesting to note that in some instances cases of dermatophytosis of the feet are complicated by an eruption which bears great resemblance to erysipelas. The importance of recognizing this condition and differentiating it from true erysipelas is of obvious importance and prompts this report of eight cases.

REPORT OF CASES

CASE 1.—C. W., a man, aged 52, presented by one of us¹ at the March 1935 meeting of the New York Dermatological Society, complained of an eruption which had appeared on several occasions over a period of a year. The eruptions were of an erysipelas-like character and usually appeared on the lower part of either leg. Sometimes the two legs were involved at the same time. They were characterized by marked erythema and swelling together with considerable local heat and pain. A few attacks were accompanied by slight constitutional symptoms. The eruption lasted for periods varying from a few weeks to two months, and the patient noticed that walking or standing aggravated the condition. There was a slight amount of scaling and fissuring in the interspaces of the toes of both feet of which the patient was completely unaware. Microscopic examinations confirmed the diagnosis of dermatophytosis of the toe spaces. After repeated cultures we were able to grow *Trichophyton interdigitale*. Blood cultures were negative.

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

1. Traub, E. F.: *Dermatophytosis with an Erysipelatous Dermatophytid of the Legs*, Arch. Dermat. & Syph. 33: 196 (Jan.) 1936.

Intradermal tests with trichophytin and oidiomycin were negative after forty-eight hours. Following the injection of trichophytin and oidiomycin, a flare up occurred on the dorsum of the left foot, the disease having been quiescent when the patient was first seen. The patient did not have a rise in temperature at this time. We had considered the erysipelas-like eruption to be an "id" and had expected a positive reaction to the intradermal tests. At the suggestion of Dr. Sulzberger and Dr. Barthel we then decided to repeat the tests and selected sites on the lower portion of the leg and the upper part of the arm. Within ten minutes of the trichophytin injections a wheal with pseudopods and a larger surrounding area of erythema developed in the arm. On the leg, surrounding the site of the trichophytin injection, a large hot, swollen erythematous reaction appeared which definitely simulated the erysipelatous eruption on the dorsum of the foot. The reaction reached its height in thirty minutes and had disappeared at the end of forty-eight hours. Oidiomycin tests were negative. Blood serum obtained from the patient was used for passive transfer tests. A normal control was selected and test sites were prepared. These sites were tested with various types of streptococci and staphylococci and with oidiomycin and trichophytin. Only the site tested with trichophytin gave an immediate positive wheal reaction. Reagents to trichophytin were apparently present in the patient's serum. We treated the patient with a fungus vaccine (*Trichophyton interdigitale*) every five days. After the fourth injection the left leg and foot were no longer red or swollen. Scaling was still present between the toes.

CASE 2.—K. A., a man, aged 35, seen June 1, 1927, complained of recurrent attacks of pain in the left popliteal space, which were followed by eruptions appearing on the left foot, ankle or leg. The attacks had been occurring over a period of twenty years. The first attack occurred while the patient was on a train journey. It was

ushered in by pain under the left knee, followed within a few hours by pain, redness and swelling in the left foot. At that time the entire left foot up to a few inches above the ankle was involved. A diagnosis of erysipelas was made. Chills and a high temperature accompanied the attack, which lasted about a week. Fever (from 102 to 104 F.) always was present during the subsequent attacks, all of which were limited to the legs.

When he was seen in June 1927 there was a red area about 1½ inches in diameter just below the tubercle of the right tibia. This area was distinctly infiltrated. The temperature ranged from 102 to 104. Dermatophytosis was present on both feet and mycelia were recovered from the right instep. The patient was seen again in March 1935 at the onset of another attack. At that time the eruption appeared on the left leg.

CASE 3.—H. B., a man, aged 52, seen in November 1923, complained of redness and swelling on the left ankle. The eruption simulated erysipelas in appearance and lasted one week. A second attack occurred in December 1924, the redness, swelling and general symptoms not being as severe as in the previous attack. A specimen from the fourth left toenail was loaded

Fig. 1 (case 1).—Left leg, showing the erysipelas-like dermatophytid, which appears close to the primary focus on that foot.

with mycelia. Culture also was positive. In August 1933, the patient appeared again, complaining of an attack which followed a great deal of walking on hard pavements. He complained too of loss of appetite and feverishness. The temperature was 99.6. There was a diffuse redness and swelling involving the left metatarsal region on the dorsal and plantar surfaces. The first and second toes of this foot also were red and swollen. The toenails and interspaces showed evidence of dermatophytosis. The trichophylin and oidiomycin forty-eight hour tests were negative. There was no immediate wheal reaction to the trichophylin injection. Nov. 1, 1935, the patient again appeared at the clinic with an erysipelas-like redness and swelling of the left leg. On this occasion the patient stated that he suffered with chills and fever. Within three days under treatment with boric acid wet dressings the redness and swelling almost entirely subsided.

CASE 4.—B. P., a woman, aged 54, complained of recurring attacks of an eruption on the left foot. The first attack appeared in July 1930 with chills, a temperature of 104 and redness on the dorsum of the left foot. This attack lasted for four days.

Fig. 2 (case 1).—Very slight degree of involvement of the left foot positive in both smear and culture.

Several attacks have occurred since, some severe, necessitating lying in bed for the duration of the attack and some mild with no fever. It is always the left foot and leg that become involved. When seen in February 1931 there was distinct swelling of the left leg without any edema. Fungi were recovered from three of the toenails and spaces of the left foot.

The involvement of the foot consisted of a slight amount of white maceration in several of the interspaces with several tiny vesicles on the toes, the lesions being so trivial that they were difficult to detect. The left leg has remained slightly increased in size with swelling since the first attack occurred.

CASE 5.—J. E., a man, aged 34, first appeared in the clinic Aug. 12, 1935, complaining of recurring eruptions on the left leg for two years. Examination revealed a marked erythema with swelling of the lower third of the leg. There was some scaling and vesiculation on the soles and toes. A diagnosis of dermatophytosis with an erysipelas-like "id" was made. Fungi were demonstrated microscopically in the first toenail on the toes and on the sole of the left foot. Positive reactions to trichophylin and oidiomycin were obtained after forty-eight hours. The patient was presented before the New York Academy of Medicine by one of us.²

CASE 6.—P. P., a man, aged 35, appeared in the clinic June 24, 1935, complaining of an eruption on the right hand and right foot. Examination revealed vesicular and scaly lesions

on the palm and fingers of the right hand. The interspaces of the toes of both feet showed vesicles, scaling and fissuring. On the dorsum of the right foot there was a large erythematous, slightly swollen area which was diagnosed an erysipelas-like "id." No constitutional symptoms were present. Fungi were demonstrated in the second right toenail. There was no immediate wheal reaction to the trichophylin test. The patient did not return and we were unable to record his forty-eight hour reaction to this test.

CASE 7.—T. D., a woman, aged 39, appeared at the clinic May 20, 1935, complaining of an eruption on the left leg. The eruption had been present for two weeks. On the middle third of the left leg there was an area about 4 inches in diameter which was fairly well circumscribed, reddish and warm to the touch. The patient had had no previous similar attacks. There were no constitutional symptoms. In the toe spaces of both feet there was some scaling and maceration. Fungi were recovered from the first toenail of the left foot. The forty-eight hour trichophylin test was negative. The oidiomycin test was positive (2+).

CASE 8.—A. Q., a man, aged 54, appeared at the clinic Aug. 17, 1936, complaining of recurring attacks of redness and swelling of the left foot. The condition had been occurring over a period of three years. Examination revealed marked redness, heat and swelling of the anterior half of the left foot. Scaling and maceration was present in all the toe spaces. Fungi were demonstrated in the second interspace of the left foot and *Trichophyton purpurem* was recovered in culture. The forty-eight hour trichophylin test was negative and the oidiomycin test was weakly positive (1+).

COMMENT

Cases of recurring erysipelas of the legs associated with infections of the feet have been reported. McGlasson³ reported a series of seventeen cases of recurrent erysipelas of the legs with dermatitis of the feet. Amoss⁴ reported a series of twenty-three cases of recurring erysipelas of the legs successfully treated with subcutaneous injections of streptococcus filtrate. Both of these authors assumed that streptococci were the causative agents. McGlasson did not find bacteria that could be considered causative agents, and Amoss stated that in a few cases he was able to grow hemolytic streptococci from the debris at the edge of the toenails. The finding of streptococci on the skin as in Amoss's cases raises an important question. In this connection it should be pointed out that Jordan⁵ of Jadassohn's clinic reported a series of 150 cases, in which he was able to demonstrate streptococci on the skin of 148. The patients were normal persons without skin lesions. The finding of streptococci on the skin is not necessarily proof that lesions have been caused by these organisms. The point here is not that these recurrent cases of erysipelas cited were not caused by streptococci but rather that some of the cases may have been attributable to fungi. In every one of Amoss's cases he found a fungous infection of the feet. Also a number of McGlasson's patients had *tinca pedis*. In commenting on McGlasson's paper, Williams⁶ in 1926 stated that "McGlasson reported cases with an erysipelas-like eruption on the legs and in each case a dermatophytosis of the feet, and that he found no bacteria which could be considered a causative factor. This immediately raises the question whether these cases of apparent erysipelas were not due to the dermatophytosis." At that time Williams stated that the secondary eruptions (the dermatophytids) the outbreak of which may be accompanied by constitutional symptoms such

as fever, headache and prostration, may vary in appearance. In his discussion of our case 1 at the New York Dermatological Society in March 1935, Williams stated:

In all these cases there is an eruption which resembles erysipelas but in those we have observed there are generally notable differences: the attacks are usually shorter, the prostration is generally less severe and the sharp margin seen in cases of true erysipelas is lacking. In most of the cases the local symptoms of tinea of the feet are mild. In the patient presented today the reaction around the site of the leg inoculated with trichophytin was identical in appearance with the erysipelous lesion on the dorsum of the foot; this, in my opinion, is conclusive evidence that the erysipelous eruption was a trichophytid. Of course it is possible that in some cases the tinea pedis serves only as a portal of entry for bacterial organisms, but it is my belief that in this case and in many others the whole process—vesicles in the feet, erysipelous eruption on the legs, enlargement of and pain in the inguinal glands—is due to a single mycotic organism and its toxins.

In addition to the already well known epidermal trichophytids, other forms have been noted: scarlatiniform exanthems and enanthems, erythrodermas, erythema nodosum-like lesions, migrating phlebitis and urticaria. We have observed also several cases of elephantiasis trichophytid in which one leg was enlarged from 2 to 2½ inches in circumference. The changes in this last variety may be either vascular or lymphatic.

There can be no question that fungi can produce an erysipelas-like eruption. We first called attention to this in our paper read at the ninth international congress at Budapest in 1935.⁷ In all our cases a clinically identifiable dermatophytosis of the feet was present. The diagnosis was confirmed by microscopic demonstration of mycelia; invariably this secondary manifestation appeared only a short distance from the primary focus of fungous infection. Fungicidal remedies applied to the focus on the feet always cleared up the complicating eruption, and it was not necessary to resort to any streptococcus or staphylococcus vaccines. Four of the eight cases gave negative forty-eight hour trichophytin reactions. In two cases the test was not performed, one patient did not return after his first visit and in one case it was positive. In our case 1 the positive reaction to trichophytin in passive transfer tests and the negative reaction to oidiomycin and streptococcus extracts indicated a causal relationship between the eruption and the fungous infection. This was further apparently indicated by the immediate wheal and flare reactions to trichophytin. In most of our cases the dermatophytosis of the feet was very mild and sometimes not even noticed by the patient. Three patients reported that the appearance of the erysipelous eruption was preceded by trauma, such as "a kick in the leg, walking a long distance on hard pavements and standing for a long period of time."

DIFFERENTIATION FROM TRUE ERYSIPELAS

It is sometimes necessary to make a differential diagnosis. The erysipelous "id" is usually found near a focus of fungous infection. The temperature is no guide, for it may be normal or as high as 104 F. There is not the definitely sharp margin or the progressive spreading of the lesion as in true erysipelas. There may be two separately involved areas present at the same time, such as in the two legs, in cases of erysipelas-like "id." The glazed appearance and brawny induration of erysipelas is not characteristic of these cases. Nor are apparent foci of pyogenic infection

found. A history of many and in some cases frequent recurrences is the rule. Constitutional symptoms are comparatively mild and of short duration. Fatalities have not been seen.

SUMMARY

1. This skin manifestation in erysipelas-like dermatophytid complicating dermatophytosis of the feet occurs near a focus of fungous infection and in our cases only in the feet or legs.
2. Fungicidal remedies applied to the focus are sufficient to cure the secondary eruptions without resorting to streptococcus serum, as used in the treatment of true erysipelas.
3. True erysipelas may be differentiated from this type of "id."
4. Trauma such as walking, a long period of standing or a direct blow may possibly initiate the appearance of this eruption.

RECURRENT ERYSIPELAS-LIKE MANIFESTATIONS OF THE LEGS

THEIR RELATIONSHIP TO FUNGOUS INFECTIONS OF THE FEET

MARION B. SULZBERGER, M.D.

ADOLF ROSTENBERG JR., M.D.

AND

DOROTHY GOETZE, M.D.

NEW YORK

According to modern concepts, pathogenic microorganisms may produce both systemic and local manifestations of disease by means of various mechanisms. One of these is through the elaboration of toxic products (toxins) that are intrinsically harmful to the tissues of the host. Another mechanism depends on the creation of a state of hypersensitivity to nontoxic, primarily innocuous constituents or products of the invading micro-organisms (bacterial allergens, fungous allergens and the like).

It appears probable today that both of these mechanisms play a part in most infectious diseases. In some diseases (e. g., diphtheria and tetanus) the toxic element undoubtedly predominates. In others (e. g., syphilis, tuberculosis, leprosy and mycotic conditions) the sensitization mechanism is the more important responsible factor. And in still other diseases (e. g., scarlet fever and the pyodermas due to streptococci and to staphylococci) it would appear as though both mechanisms were involved, and to different degrees, varying not only from disease to disease but perhaps even from case to case.

In erysipelas, the streptococcus toxin has always been considered the major responsible agent. While this is undoubtedly correct it is probable that here too sensitization to streptococcus allergens may be of importance. This concept is supported, for example, by the observation of both local and systemic erysipelas-like manifestations occasionally following the injection of foreign proteins or of other nonliving and nontoxic allergens in susceptible individuals. Those who have had some experience with the subcutaneous and particularly with the intracutaneous administration of various allergens (such as trichophytin and tuberculin) have surely

7. Traub, E. F., and Tolmach, J. A.: Dermatophytosis: Deliberations Congressus Dermatologorum Internationalis IX, Budapest, September 1935, pp. 714-719.

From the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital, Columbia University.

encountered local reactions consisting of sterile, non-toxic, highly inflamed erythema and edema with fairly sharply outlined, advancing, circinate borders and accompanied by sudden fever, chills and malaise—in short, the picture of erysipelas. The first experience with such a reaction is necessarily disturbing until the observer is reassured that these manifestations are due not to any accidental infection but to an allergic reaction to the sterile, nontoxic injected extract.

In view of this it must be recognized that pictures identical with or closely simulating erysipelas may not all be due to the action of *Streptococcus erysipelatis* and its toxins. Thus a doubt must exist as to the etiology of certain erysipelas-like cases, unless the rôle of the streptococcus has been definitely proved.

At dermatologic meetings in the past few years, cases have been reported and demonstrated that resembled recurrent erysipelas and occurred on the lower legs in men suffering from dermatophytosis of the feet.¹ In the presentations and in the discussions, Williams, Traub and one of us stated that these manifestations were not necessarily due to true erysipelas and that another hypothesis might be considered with regard to the pathogenesis and etiology of the disease syndrome presented. This hypothesis suggested that at least some of these cases might be due to the hypersensitivity of the tissues to allergens emanating from the foci of fungus infection on the feet. It was pointed out in support of this hypothesis that these cases presented certain peculiarities in common, notably that the adequate treatment of the dermatophytosis of the feet resulted in the complete disappearance of the erysipelas-like symptoms and also apparently prevented their recurrence. Williams and Traub mentioned that they had observed a series of such cases in which, after successful therapy of the dermatophytosis, there were no recurrences of the formerly frequent erysipelas-like attacks. (In one case of Williams, for example, there had been recurrences at irregular intervals over a period of twenty-one years. Treatment of the dermatophytosis resulted in a cure which is now of over three years' duration.)

Since it is a well known fact that chronic recurrent erysipelatos eruptions not infrequently lead to chronic lymphedema and elephantiasis, it is surely interesting to note that Allen,² in his study of the causes of lymphedema of the extremities, considered five out of fifty-seven cases of inflammatory lymphedema to be due to trichophytosis of the feet.

We here wish to present observations on four cases of recurrent erysipelas-like lesions of the lower legs, associated with dermatophytosis of the feet. We believe that this syndrome is sufficiently common to be of some general medical significance and that our observations in these cases may have practical as well as theoretical interest.

REPORT OF CASES

Three of our cases are here reported for the first time. The fourth case (C. W.) was first presented by Traub³ before the New York Dermatologic Society, and subsequently by Sulzberger^{1c} before the Bronx Dermatologic Society.

CASE 1.—B. B., a white man, aged 45, a salesman, seen at the Skin and Cancer Unit of the New York Post Graduate Medical School and Hospital June 11, 1936, complained of redness and swelling of the left lower leg for the past three days, and of malaise, fever and generalized aches and pains during the same period. He said that for the past four years he would have what he termed an "attack" about once every two months but that in the past six months he had been having the attacks as often as once every two weeks. He stated that the seizures were characterized by the sudden appearance of redness and swelling of the left lower leg, associated with fever, malaise and generalized aches and pains. The fever had been as high as 104 F. in some instances, and the systemic upset with each attack was sufficiently severe and of sufficient duration to confine the patient to his bed for from two to three days. He further stated that he had noticed that, prior to the onset of each attack, he would experience a feeling of heaviness or a sensation of dragging in the left leg.

Intradermal Reactions in Case 1

Test	Immediate Urticarial Wheal Reactions Read at 10 Minutes	Late Tuberculin Type Papular Reaction Read at 48 Hours
a. Normal skin, arm, trichophytin 1:30, 0.05 cc.	++ wheal	0

* These tests were done during attack.

† These tests were done in an interval between attacks.

in attack.

These sensations would manifest themselves from six to twelve hours before the onset of the more dramatic symptoms. Incidentally, all his attacks had been confined to the left leg, and the involved area was always the same. The skin involvement began just above the ankle and went about two thirds of the way to the knee, affecting mainly the anterior and anterolateral surfaces. The posterior surfaces had never been involved. The patient stated that for about the same duration as he had experienced the attacks (four years) he had a more or less continuous itching and burning sensation on and between the toes, which had also become more pronounced in the last six months.

The family history was negative.

The past medical history was negative.

On admission to the clinic the patient presented a markedly swollen and reddened left lower leg. The skin over this area was tense, shiny and warm. The affected area began above the ankle and extended about two thirds of the way to the knee and gradually faded into normal skin around the anterolateral aspects of the leg. The toes and the interspaces presented much macerated tissue, with cracks in some of the interspaces.

The general physical examination revealed no abnormalities beyond those described.

The Wassermann and Kahn reactions were negative.

Microscopic examinations of the scrapings from the affected areas between the toes were repeatedly positive for a hyphomycete, with a finding of numerous typical branching mycelia characteristic of a pathogenic fungus. It is perhaps noteworthy that this fungus failed to grow in repeated attempts at culture on suitable mediums.

No streptococcus could be demonstrated extemporaneously or in culture, either from the scrapings between the toes or from the tissue fluid recovered from the leg lesions. The tissue fluid from the leg lesions was also negative for tinea.

Experimental Data.—Both the normal skin and the affected site, during and after an attack, were tested by the intracutaneous injection of 0.05 cc. of the following extracts: trichophytin 1:30, oidiomycin 1:100, old tuberculin (Koch) 1:1,000, vaccine of *Streptococcus haemolyticus* and *staphylococcus toxoid*. The injection sites were observed both for the immediate wheal type of reaction at from ten to twenty minutes after injection, and for the late papular tuberculin type of reaction at forty-eight hours after injection. The results of these tests are set forth in the accompanying table.

The results of these injections demonstrate a marked forty-eight hour type reaction to old tuberculin 1:1,000. This finding is not sufficiently unusual to make it necessary to consider it significant in this case.

The significant manifestations seem to be:

(a) The complete lack of forty-eight hour tuberculin type of reaction to trichophytin, despite the demonstrated presence of pathogenic fungi in the foot lesions.

(b) The strongly positive immediate wheal reaction to trichophytin. This is a finding so unusual in individuals with common fungous disorders who have never received injections of trichophytin that we are inclined to consider it of some as yet inexplicable significance.⁴

Patch tests with undiluted trichophytin and oidiomycin were negative on both the previously affected and the normal skin.

The patient's urticarial wheal reaction to trichophytin was accompanied by specific reagins; i. e., specific Prausnitz-Küstner antibodies to trichophytin were demonstrated in the patient's serum. This result may be considered of significance since Prausnitz-Küstner reagins to trichophytin are a most uncommon finding in patients with uncomplicated forms of fungous infection.⁴

Therapy.—Treatment was begun at the time of the first presentation, June 11, and during an acute attack. It consisted of local treatment of the dermatophytosis of the feet, in the form of potassium permanganate soaks, followed by topical applications first of gentian violet and then of Castellani's basic fuchsin tincture.

In addition to the local treatment, we inaugurated immunologic treatment by means of repeated injections of trichophytin, both intracutaneously and subcutaneously, July 23. To date the patient has received more than twenty intracutaneous and more than twenty subcutaneous injections.

Course.—Between June 11 and July 21 we observed four typical erysipelas-like attacks. The first was the one presented at the time the patient was first seen, June 11. This attack subsided within two days. Subsequent similar attacks appeared June 20, July 9 and July 21.

As stated, trichophytin desensitization was begun July 23, and since that date there have been no further attacks. This is the longest period of freedom from attacks experienced by the patient since the beginning of his complaint four years ago.

The skin reaction to trichophytin at the time of the last intracutaneous test, November 20, remained unchanged. The immediate wheal reaction was still present in approximately its original intensity, and there was no late, forty-eight hour, tuberculin type, papular reaction. (One of us⁵ has had frequent occasion to point out the fact that, as a rule, the immediate

wheel type of skin sensitivity cannot be materially reduced by repeated injections, whereas the late tuberculin type of skin response can be regularly diminished by repeated intracutaneous injections of the specific allergens.)

CASE 2.⁶—E. C. H., a white man, aged 44, seen in the private practice of one of us, on April 15, 1935, complained of pain, tenderness and swelling of the left lower leg for the past week. The attack had begun with an oral temperature of 101 F. and had been accompanied by malaise and general symptoms. The patient stated that for the past eleven years he had been suffering from recurrent attacks of a similar nature. The seizure preceding the present one had occurred two months previously and was inaugurated by a chill and temperature of 103. The patient had been confined to a hospital for three weeks during his last attack. The local manifestations had always been confined to the lower anterior portions of the left leg.

On examination there was a more than palm sized, bluish red edematous swelling of the anterior portion of the lower left leg. The involved area faded gradually into the normal surrounding skin. There was tenderness, but the skin surface of the bluish red swelling was of approximately the same temperature as that of the surrounding normal skin. The consistency was firm and elastic.

The left foot exhibited considerable maceration and scaling of the sole and some maceration and several deep fissures between the third, fourth and fifth toes.

The right foot presented less marked evidence of eczematous dermatophytosis, with slight scaliness of the sole and of the interdigital webs.

Extemporaneous microscopic examination of scales from the left foot was positive for tinea, revealing numerous branching mycelia.

Experimental Data.—No cultural studies for fungi or streptococci were made. Intracutaneous skin tests with trichophytin and oidiomycin revealed a moderate immediate wheal and flare reaction to trichophytin and none to oidiomycin.

The late, forty-eight hour, tuberculin type reaction to trichophytin was moderately strong, while the late reaction to oidiomycin was pronounced.

No attempt was made to demonstrate Prausnitz-Küstner reagins in this case.

Therapy.—The dermatophytosis of the feet yielded to topical applications, and the leg lesion subsided rapidly.

Under prophylactic dermatologic measures (nightly soaks with 0.5 per cent sodium thiosulfate solution and the application of a mild antiparasitic ointment) the feet have been kept free from lesions. There has been no recurrence of the erysipelas-like attacks. The period of observation was one year and seven months.

CASE 3.⁷—S. N., a white man, aged 40, first seen in office practice, Nov. 3, 1936, had been confined to bed for the last few days because of a painful swelling of the dorsum of the left foot. The attack had been initiated by headache, malaise, chills and a sharp rise in temperature to 103 F. There was a history of numerous preceding attacks of similar nature and in the same site, about once a year for eight or nine years, and a history of "athlete's foot" of many years' duration and preceding the erysipelas-like attacks.

On examination there was a fairly sharply circumscribed erythematous swelling of all the toes and of the dorsum of the left foot; there was a lymphangitic strand on the lower part of the left leg and a palpable tender lymph gland in the left inguinal area. The interdigital spaces presented maceration and there was a typical papulovesicular dermatophytosis of both soles. The third and fourth interspaces on the left foot were the site of deep fissures.

Under local treatment (soaks with 0.5 per cent aqueous solution of silver nitrate and application of boric acid ointment) the systemic manifestations, the leg lesions and the dermatophytosis rapidly subsided. There was a residual chronic lymphedema of the anterodorsal portion of the left foot and of the dorsa of the toes. On the toes and at the proximal ends of the interspaces there were numerous elevated papillomatous warty excrescences, such as are often found in elephantiasis of the extremities.

6. This case was referred by Dr. DeWitt Stetten of New York.

7. This case was referred by Dr. Edgar Mayer of New York.

4. This subject is discussed further by:
Sulzberger, M. B., and Kerr, Phyllis: Trichophytin Hypersensitiveness of Urticarial Type, with Circulating Antibodies and Passive Transference, *J. Allergy* 2: 11 (Nov.) 1930.
Wise, Fred and Sulzberger, M. B.: Urticaria and Hay Fever Due to Trichophytin (Epidermophyton Interdigitale), *J. A. M. A.* 95: 1504 (Nov. 15) 1930.
Sulzberger, M. B.: Experiments in Passive Transference of Urticarial Hypersensitiveness to Fungous Extracts, *J. Immunol.* 23: 73 (July) 1932.
Tomlinson, W. J.: Trichophytin Hypersensitiveness: Report of a Case with an Immediate or Reaginic Type of Reaction, *J. Allergy* 6: 573 (Sept.) 1935.
5. Sulzberger, M. B.: Allergy in Dermatology, *J. Allergy* 7: 385 (May) 1936.

Cultures taken from the interdigital fissures on the day of the first examination showed *Streptococcus haemolyticus* and *Staphylococcus aureus*. Unfortunately, no mycologic, microscopic or cultural study was made.

The intracutaneous skin tests with trichophytin and oidiomycin revealed a slight immediate wheal and flare reaction to trichophytin and no reaction to oidiomycin.

At forty-eight hours the tuberculin-type papular reaction to trichophytin was scarcely visible, while a moderate to marked reaction was present at the oidiomycin site.

In this case no reagins to trichophytin were demonstrable in the blood serum.

Case 4 is not described in detail here because it has already been reported elsewhere⁸ and forms the first case of a report by Traub and Tolmach.⁹

CASE 4.¹⁰—C. W., a white man, aged 52, seen in the service of Dr. C. M. Williams at the Skin and Cancer Hospital, complained of recurrent erythematous swellings of the anterior portion, sometimes on the right and sometimes on the lower part of the left leg, with considerable local heat, pain and tenderness. There was typical mycotic scaling and maceration of the interspaces of both feet, from which fungus mycelia were repeatedly demonstrated on microscopic examination but failed to grow despite many inoculations on suitable mediums.

Intracutaneous skin tests with trichophytin, oidiomycin and vaccines of staphylococci and streptococci yielded a large immediate wheal and flare reaction solely to the trichophytin and no immediate reactions to the other extracts.

In contrast to the large immediate wheal response, the forty-eight hour tuberculin type reaction to trichophytin was completely negative!

One of us, in immunologic studies of this case, carried out for Drs. Traub and Williams, showed that the intracutaneous injection of 0.1 cc. of trichophytin, when performed on the lower leg, produced not only a wheal and flare up but also an almost palm-sized, hot, erythematous swelling, exactly duplicating the clinical lesion from which the patient suffered. On the other hand, injections of trichophytin in the skin of parts of the body other than the lower leg, and injections of other fungous and bacterial extracts in any skin area did not result in reactions simulating the spontaneous clinical lesions.

Extensive Prausnitz-Küstner experiments were carried out with the serum of this patient. There were no demonstrable reagins to vaccines of streptococci, staphylococci or monilias but a high titer of reagins to trichophytin was repeatedly demonstrable.

The tinea of the feet yielded to classic dermatologic treatment, and to date there have been no recurrences of the erysipelas-like attacks.

COMMENT

The picture of recurrent erysipelas-like attacks of the lower legs is not uncommon, and the association of this syndrome with dermatophytosis has been mentioned by various observers. In addition to cases reported by Traub,¹ Williams and others in the more recent literature.¹ McGlasson,¹¹ for example, in 1926 devoted an article to the subject of recurrent erysipelas of the legs and dermatitis of the feet. In McGlasson's report of sixteen cases it was assumed that dermatitis of the feet opened portals of entry for the etiologic agent (*streptococcus*) and that the attacks were those of true recurrent erysipelas. In the later literature the attacks have been regarded as possibly due to a sensitivity to fungi and their products, emanating from the foci of mycotic infection on the feet. It seems to us that both these hypotheses are still distinctly tenable but that certain older experimental and clinical data, and particularly several observations in our present cases, speak rather in favor of the latter assumption.

The sum of these observations seems to lend support to the idea that at least some of these cases are erysipelas-like dermatophytids. In the first place, the older animal experiments of Jadassohn¹² and of one of the present authors¹³ have demonstrated the rapid passage of fungous elements from primary foci; secondly, the observations of Jadassohn and Peck¹⁴ and of Peck¹⁵ have shown that, in human beings with dermatophytosis, irritation of foci on the feet produces an absorption and dissemination of the fungous allergens. It is further noteworthy that "ids" of the lower legs in the form of sudden painful swellings (erythema nodosum-like ids) and of lymphangitis and lymphadenitis have previously been described.¹⁶ In one case,¹⁷ fungi were demonstrated even in the inguinal lymph glands.

It is therefore by no means to be excluded that the recurrent painful swellings of the legs in our cases may be due to fungous allergens; and it is, of course, well known that many trichophytids produce general symptoms with sudden fever, malaise, prostration and even generalized glandular swellings and enlargement of the spleen (the systemic disease properly called trichophytosis¹⁸).

Those manifestations in several of our cases, which seem to speak rather for the dermatophytid nature of the erysipelas-like syndrome, are, above all, the demonstrated alterations in their immunologic response to trichophytin. The negative trichophytin reaction at forty-eight hours, seen in cases 1, 3 and 4, is not entirely unknown but is surely exceptional in cases in which fungi have been demonstrated in lesions of the foot. The same statement applies with at least equal force to the moderate to strong immediate wheal reaction to trichophytin, as exhibited by all four of our cases, and to the finding of Prausnitz-Küstner reagins to trichophytin, which were demonstrable in cases 1 and 4. All these observations certainly evidence an atypical immunologic response to the fungous infection and to the fungous allergens. Moreover, it is possible that the failure of the microscopically demonstrated fungi to grow on culture mediums, as seen in cases 1 and 4, may also be due to the influences of a peculiar immunologic state; for example, to the possible presence of growth inhibiting antibodies.¹⁹

Further observations that suggest the mycotic and possible "id" nature of the syndrome in our cases are: (a) the absence of streptococci on culture (case 1); (b) the local exact reproduction of the clinical lesion by means of a specific intracutaneous injection of trichophytin in the skin of the lower leg, and the failure to produce such an erysipelas-like response with trichophytin in distant, nonsensitive skin areas, as well as the failure to produce nonspecific erysipelas-like responses with extracts of various other microorganisms, such as monilia, streptococci and staphylococci⁹ (Traub and Tolmach's case, i. e., our case 4); (c) the apparent prophylactic effect of specific immunologic procedures in the form of trichophytin injections

(case 1), and (d) to a certain degree, at least, the cessation of erysipelas-like attacks when the dermatophytosis of the feet was kept under control.

All these facts suggest that the erysipelas-like syndrome could be considered a dermatophytid in the form of a local allergic cellulitis and lymphangitis and of a systemic allergic response to fungous products emanating from the dermatophytosis of the feet.

However, it must be borne in mind that, at least in some cases, a fortuitous combination of erysipelas and dermatophytosis may occur, while in others the dermatophytosis may open the portals for the entrance of the streptococcus of erysipelas; in still others the syndrome may be produced by fungi alone or by fungi in combination with streptococci or even by some still unknown other mechanism. It seems to us that our case 3 is one in which the dermatophytosis may have prepared the way for the entrance of the streptococcus, while in cases 1, 2 and 4 no evidence incriminating a streptococcus could be brought forward.

In summing up, we believe that it must remain the problem of future studies to decide as to the exact etiology and pathogenesis of each individual case of the type here under discussion and that it will be essential in the future to demonstrate the presence of *Streptococcus erysipelas* in lesions of the leg before it can be concluded that such erysipelas-like syndromes of the lower legs are necessarily true erysipelas.

While our observations only lend additional support to the concept of the existence of erysipelas-like dermatophytids of the lower legs, they seem to prove conclusively a point which is, in itself, not without practical significance; i. e., that, as previously emphasized by Williams,¹⁰ proper and adequate dermatologic management of the existing dermatophytosis of the feet and prevention of its exacerbations will tend to prevent the recurrences of erysipelas-like attacks of the lower legs. Moreover, in consideration of the results in our case 1, it is possible that immunologic treatment with repeated injections of trichophytin may be of some influence in the prophylaxis of the erysipelas-like reactions.

SUMMARY AND CONCLUSIONS

1. The occurrence of erysipelas-like attacks on the lower legs, associated with active dermatophytosis of the feet, is not uncommon.

2. Some of these cases may be recurrent erysipelas-like dermatophytids of the lower legs and not true erysipelas.

3. These cases are likely to present aberrant immunologic responses to trichophytin in the form of (a) positive immediate wheal responses to intracutaneous injections, (b) a negative or weak forty-eight hour tuberculin type of reaction, and (c) the presence of Prausnitz-Küstner reagins to trichophytin. These immunologic peculiarities and the reproduction of the clinical lesion by means of a trichophytin injection (in one case) are regarded as lending support to the hypothesis of the dermatophytid nature of the erysipelas-like syndrome here presented.

4. Whatever the pathogenesis and etiology of the erysipelas-like attacks (whether they are due to streptococci, to fungi, to their combination or to other unrelated agents and factors), the proper and adequate dermatologic treatment of the mycotic disorder of the feet seems to offer an excellent means of preventing recurrences of the erysipelas-like syndrome of the legs.

DINITROPHENOL AND DESICCATED THYROID IN THE TREATMENT OF OBESITY

A COMPREHENSIVE CLINICAL AND LABORATORY STUDY

SAMUEL SIMKINS, M.D.

PHILADELPHIA

(Concluded from page 2117)

SKIN REACTIONS

The most common toxic action observed with dinitrophenol is a skin rash.⁸¹ The incidence reported varies from 15 per cent⁸² to 23.4 per cent.⁸³ There is no way of predicting sensitivity to the drug. The Derrien test is now known to be of no value in this respect.⁸³ Skin tests are of no value; neither the direct test (patch test, scratch test, intradermal wheal test) nor the indirect or passive transfer test (Prausnitz-Küstner test).⁸⁴

In the present series there was a total of thirty-two patients who showed skin reactions. Of these, a few developed more than one type of skin lesion.

1. Simple pruritus occurred in four patients. It disappeared in three without the medication being discontinued. In the fourth (a patient with vasomotor rhinitis) the dinitrophenol was resumed safely, shortly thereafter. Of the four patients, one had hay fever and one vasomotor rhinitis. One reaction occurred in the fourth week, one in the seventh week, and two in the seventeenth week of continuous dinitrophenol medication.

2. Macular rashes developed in three patients, all within two weeks after the institution of dinitrophenol therapy. In all patients the dinitrophenol was continued, and the rash disappeared spontaneously within three days.

3. Papular and maculopapular rashes developed in twelve patients. One was allergic to many foods and had severe migraine at the time of her menses; another suffered from migraine. The rash was usually papular and developed in the second to the eighth week, persisting from one to five days. Three of the rashes were barely pruritic; nine varied greatly in the degree of pruritus. In two patients the rash appeared twice, several weeks apart. In all twelve patients the rash disappeared spontaneously as the medication was continued.

4. In four patients there was marked swelling and redness of the hands and feet. The time of onset varied greatly. In one it developed after the ingestion of only four 100 mg. capsules. After the lapse of one day, medication was resumed without recurrence of the rash. Another developed marked manifestations in the second week and was able to resume medication after a short lapse. A third patient developed the reaction after three and one-half months of medication. The catholicity of skin reactions to dinitrophenol is well illustrated by this

patient, a woman of 28, who developed four types of reactions during an intensive course of dinitrophenol in therapeutic dosage. A generalized pruritic, papular eruption appeared on the fourth day of medication and disappeared spontaneously after a few days. At three and one-half months she developed marked redness and swelling of the hands and feet, which disappeared as soon as the dinitrophenol was omitted. The medication was resumed safely within a few days. A month later there occurred itching of the neck together with redness of the skin, which persisted one week. At five and one-half months she developed several large, painful subcutaneous nodules that disappeared spontaneously after a few days. The fourth patient had tabes and developed urticaria in the fifth week. Two days after the drug was stopped the urticaria disappeared, and the hands and feet became red and swollen. Soreness and tenderness of the hands and feet persisted eleven days after the drug was discontinued.

5. Urticaria occurred in ten patients. In five the rash was generalized; in the remainder the rash was scattered and limited chiefly to the extremities or to the buttocks and chest. Of the first five patients, one suffered an extremely violent febrile reaction, which will be described later; the other four were afebrile. All five rashes developed within the first ten days of medication. Summing up the ten cases, two were continued on the dinitrophenol, even when urticaria had developed, without mishap. Four patients, who had developed urticaria, were shortly afterward given the drug again without recurrence of the rash. Another patient developed prompt recurrence of the urticaria when medication was resumed. The other three patients in the series did not have the drug repeated. Of the ten patients one, who had a few scattered hives during the second week of medication, eventually developed cataracts.

In the series of thirty-two patients who developed skin rashes, there were twenty-nine nonallergic and three allergic (one vasomotor rhinitis, and two allergic to various foods). Of these three, one had migraine. Two others of the thirty-two had migraine. Contrast these figures with the number of allergic patients in the entire series. Of a total of 159 patients, fourteen were allergic (three with hay fever, ten with a history of former urticaria, and one with vasomotor rhinitis), as well as six with migraine. Of the fourteen, only three developed skin manifestations (one pruritus, one maculopapular rash and one urticaria). These results support Matzger's⁸⁴ conclusion that dinitrophenol reactions are not allergic in character.

6. In the tenth week of dinitrophenol therapy one patient developed an eruption remarkably simulating pityriasis rosea. The rash disappeared in ten days, without interdiction of the drug.

The incidence of skin reactions was rather high (thirty-two cases in 159, or 20.1 per cent), which compares with McGavack's⁸⁵ figures of 23.4 per cent.

ALOPECIA

One patient developed alopecia. A search of the literature discloses no other case report. Hitch and Schwartz⁸⁶ have recently reported an exfoliative dermatitis following dinitrophenol therapy, in which a certain degree of alopecia was present:

Mrs. M. C., aged 47, white, who weighed 231 pounds (105 Kg.), took an average of five 100 mg. capsules of sodium

dinitrophenol daily between April 5, 1935, and June 21, 1935, with a resultant loss in weight of 32 pounds (14.5 Kg.) and no apparent ill effects. Medication was resumed with three capsules daily on Aug. 30, 1935, at which time she weighed 201 pounds (91 Kg.). September 5 she began to complain of persistent pain in one arm, which grew steadily worse. At that time she noticed that her hair was falling out slightly. September 20 (at which time the dose was four capsules daily) she developed marked edema of the ankles. This condition continued until November 11, when the drug was discontinued. The alopecia became progressively worse. Local treatment for six weeks was of no avail. There was marked scaling and redness of the scalp together with the development of numerous small ulcers. The hair fell out, in clumps, in scattered areas throughout the scalp. The alopecia continued for two months, and then the condition of the scalp began to improve. The hair is gradually growing in, and the scalp is beginning to approach normality in its appearance.

URTICARIA

C. C., a white woman, aged 23, who weighed 130 pounds (59 Kg.), took an average of $4\frac{1}{2}$ grains (0.3 Gm.) of sodium dinitrophenol daily between Jan. 22 and March 16, 1935, with no apparent ill effects. The weight loss was slight (5 pounds, 2.3 Kg.). May 6 she resumed medication with the same dosage. On May 12 itching of the thighs developed. The next morning generalized urticaria appeared. The patient felt drowsy and vomited. Epinephrine hydrochloride, 5 minims (0.3 cc.) by hypodermic injection, gave prompt but only temporary relief. May 14, tremendous urticarial lesions appeared, especially involving the wrists and ankles. The hands and feet were immensely swollen and intensely hot and red. Practically the entire body was covered with large wheals. The temperature was 100 F., the pulse 112, the respiration 28, and the blood pressure 112 systolic, 64 diastolic. Examination otherwise was negative. Epinephrine again gave prompt relief. Ephedrine and calcium by mouth were prescribed. The next day the urticaria decreased somewhat. As old lesions disappeared, new ones developed. The temperature and respiration were now normal, but the pulse remained rapid (112). By May 16, nearly all the lesions were gone. New lesions cropped up intermittently for three weeks thereafter, though they were so scattered as to cause very little discomfort.

PERIPHERAL NEURITIS

It is only recently that the rôle of dinitrophenol in the causation of peripheral neuritis has been noted.⁸⁶ The striking symptoms are practically always sensory, the legs and feet being affected first, the arms and hands next. Various paresthesias, such as numbness and "pins and needles," develop and after the drug is stopped clear up slowly, within three weeks to two months. Cases of motor weakness, such as foot drop, are rare.⁸⁷ The weakness disappears rapidly after the drug is stopped, usually within a week. After the recovery period, the medication may usually be resumed at a lower dosage level without further symptoms.⁸¹ In the author's series there were only four frank cases of peripheral neuritis. The symptoms developed very gradually in all, and only after prolonged medication (from the fourth to the tenth week). The condition persisted for weeks and gradually cleared up after the medication was discontinued.

A very interesting feature is the development, in a few patients, of disturbances of the sensation of taste, or dysgeusia.⁸⁸ Five patients developed loss of taste, especially for salt, sweet, sour and the like, as well as numbness and tingling of the tongue, usually within the

fifth to the seventh week. In no case was the drug interdicted. In one patient the loss of taste lasted only two days, in another five days; in the other three patients it persisted several weeks, disappearing spontaneously even though the drug was continued.

BLOOD CHANGES

In view of the close chemical relationship of dinitrophenol to benzene, cases of diffuse bone marrow depression following dinitrophenol therapy might be expected a priori. The common factor in dinitrophenol, aminopyrine, arsphenamine, benzene and so on, is the benzene ring. In animal experiments no apparent changes in red or white blood cells have been noted even when massive doses of dinitrophenol were given over periods as long as six months.⁸⁹ The first case of granulopenia following dinitrophenol administration was reported in 1934.⁹⁰ Since that time, seven similar cases have been reported,⁹¹ of which two proved fatal.⁹² In every one the dosage was nontoxic. Tainter, Cutting and Stockton⁴³ found no alteration in the fragility of the red cells. One case of urticaria presented petechiae of the legs and feet.⁹³ In a series of 170 patients no agranulocytosis developed.⁹⁴ In the present series no clinical cases of agranulocytosis developed. Eleven patients were studied carefully with repeated, complete blood counts during prolonged courses of dinitrophenol medication, without any significant changes being noted. Hence one must agree with Tainter and his colleagues³⁴ in their conclusion that dinitrophenol does not affect the blood cells except in rare instances of "some preexisting idiosyncrasy or defective constitution in the individual patient, in whom dinitrophenol or any other drug or toxin may act as a precipitating agent."

MENSTRUAL EDEMA

A subject of intrinsic interest that has not received the attention it merits is menstrual edema. Thomas⁹⁴ described two cases of extensive, generalized edema occurring only at the time of the menses. Such a phenomenon is not limited to women with clinically recognizable gland dysfunction but occurs in varying degree in presumably normal individuals.⁹⁵ The explanation of the phenomenon—the shift in water balance—is not clear. In the present series eighteen women complained of feeling "bloated" shortly before or during their menses. Of the eighteen, only six gained weight at the time of the catamenia. In the entire series a total of fourteen gained weight at the time of the menses. Ten were given dinitrophenol exclusively, and four 2 grains (0.13 Gm.) of desiccated thyroid daily in addition to the dinitrophenol. The gain in weight was variable, ranging from 2 to 5 pounds (0.9 to 2.3 Kg.). After the menses were over, the increment in weight was usually lost rapidly.

MENSTRUAL CYCLE

There is a marked, though totally unpredictable, action by dinitrophenol on the menstrual cycle in many women. This effect was noted in fifteen patients. While it is true that "most of the menstrual disorders common in the obese are corrected by proper diet alone,"⁹⁶ the change in menses in many patients is so marked and occurs so soon after the institution of drug therapy (before there has been any significant weight loss) that one must conclude that direct action of the drug is involved. Three patients who had irregular, delayed menses became regular promptly. On the other hand, two whose menses had been perfectly normal became irregular; in one, the catamenia was a week late and scanty; in the other, four days delayed and very profuse. In the latter patient, dysmenorrhea and menstrual headache vanished for the first time in years. In two patients the menses became very scanty, in one very profuse. Four patients began to have early, scanty menses. One patient became totally irregular and one became amenorrheic. In contrast, a young adult, who had been amenorrheic for eighteen months following childbirth, began to menstruate regularly but somewhat scantily.

DINITROPHENOL CATARACTS

The *bête noire* of dinitrophenol therapy is cataracts. It is only slightly more than a year ago that the first reports crept into the literature.⁹⁷ Since that time numerous cases have been reported.⁹⁸ The pathogenesis is obscure.⁹⁹ No case has shown spontaneous resolution. The shortest time reported for the development of cataracts is one month, the longest twenty-one months. The number of cases reported ranges between fifty and a hundred.¹⁰⁰ The actual incidence of cataracts is very difficult to estimate, as there are few reports in the literature of extensive clinical studies of dinitrophenol. Tainter, Stockton and Cutting³⁴ had one case in 170 patients, Hill one in sixty-eight;¹⁰¹ I had one in 159. Horner¹⁰⁰ estimates from 0.1 to 1 per cent. Undoubtedly many cases of recent origin have not been linked to dinitrophenol, and in view of the long latent period before the cataracts become clinically manifest and in view of the extremely widespread usage of the drug both with and without medical supervision, a rapidly increasing number of cataracts may be expected in the near future. An interesting feature, which has received only slight attention, is disclosed by a careful study of almost all cases reported in detail. It consists of the fact that patients who developed cataracts are those who, in nearly all cases, had more than one course of dinitrophenol. It is during the second or subsequent course that dimness of vision begins.

Even now, with the evidence pointing to dinitrophenol as the causative agent of these cataracts, many deny the rôle of the drug. As they point out, during the latter part of the World War many workers in

French munition plants showed toxic symptoms, but there are no records of any cataracts. Moreover, in recent work Horner¹⁰² has found cases in which similar cataracts have occurred without the ingestion of dinitrophenol. "Dinitrophenol can scarcely be the essential factor when identical changes are seen in those who have never taken the drug."

Horner, Jones and Boardman¹⁰³ reported one case in which there was transient blurring of vision, which disappeared after a few doses. Bilateral, faint, lenticular opacities were discovered, which did not progress. In the present series, three patients developed intermittent blurring of vision at the beginning of dinitrophenol therapy, which disappeared spontaneously after a few days. To date (fifteen months, seventeen months and twenty-two months after the institution of therapy) no lenticular changes have appeared.

Vitamin C is present in the normal lens in high amounts.¹⁰⁴ With age and cataract formation, the vitamin C diminishes and may become absent.¹⁰⁵ The drop in vitamin C parallels the drop in glutathione content and the drop in its oxidation activity. "The vitamin C content of organs depends on the amount of ascorbic acid fed and decreases as the metabolic rate of the tissue is increased."¹⁰⁶ The metabolic rate of organs is increased by the administration of thyroid extract, and alpha-dinitrophenol. The value of vitamin C may be presumed to lie in the maintenance of a clear lens. Consequently, increased permeability of the capsule¹⁰⁷ may result in lessened vitamin C content of the aqueous and thus predispose to cataract formation. In naphthalene poisoning (cataracts) there is a marked decrease in vitamin C concentration of the lens and aqueous, possibly because of increased permeability of the capsule.¹⁰⁸ Intravenous injection of vitamin C in animals gave conflicting and inconclusive results.¹⁰⁹ In his preliminary report, Josephson¹¹⁰ gave results of treatment of cataract cases with vitamin C. His treatment employed the intravenous use of vitamin C, in part at least. He reported that the swelling of the lens capsule was reduced and that the lens became more transparent.

DINITROPHENOL CATARACTS

Mrs. M. C., aged 48, was given sodium dinitrophenol, in an average dose of from 300 to 400 mg. daily from July 27 to Oct. 8, 1934, with a loss of weight from 157 pounds (71 Kg.) to 144 pounds (65 Kg.). From Oct. 8, 1934, to March 26, 1935, the drug was discontinued. By this time her weight had regressed to 153 pounds (69 Kg.). Sodium dinitrophenol was again given, in the same dosage, until April 29, 1935, when her weight was 145 pounds (66 Kg.). At that time there were no visual complaints. The drug was then discontinued. Aug. 3, 1935, while bathing at a seaside resort, she became cold and complained of marked chilliness. Within a few minutes, huge urticarial wheals covered the entire body with the exception of the face. The urticaria disappeared within an hour. Three hours later she developed diplopia when she closed her left eye. The condition became gradually worse until September 4, when an ophthalmologist discovered bilateral cataracts. Shortly afterward, dimness of vision began to develop and grew rapidly worse during December. The diplopia (right eye) persisted until vision was completely lost at the end of December 1935.

Dr. O. F. Merston reported that examination, Sept. 4, 1935, showed the eyes externally entirely normal. Muscle balance was normal for distance and near. The pupils were round, central, and equal, and reacted to light and in accommodation. The vision of each eye was 6/9. Both lenses showed numerous fine white flaky deposits, resembling naphthalene, scattered throughout the cortical substance, the area immediately beneath the capsule being clear. The right eye was more affected than the left. The eyegrounds and vessels were normal. In six weeks there was an increased myopia of 1.50 diopters. The flakes were more pronounced. Vision of each eye was 6/9—1. Four weeks later the vision of the right eye was 6/30 and of the left eye 6/12½. No view of the backgrounds was possible. The right lens was a beautiful pearly white color and the flakes in the left eye were much more confluent. Two weeks later the right was matured and the left vision 3/60. There was still a narrow clear area immediately beneath the capsule. Treatment was of no avail. Dr. Luther C. Peter operated on the right eye Dec. 30, 1935, and the patient now has 6/6—vision in the eye. The left eye has not been operated on. Reexamination of the right eye following cataract extraction showed no retinal lesion.

By Feb. 22, 1936, the left cataract was mature. Only slight light perception was left. The whole lens was now pearly white as the right lens had been and was ready for extraction. On the basis of experimental work already described, I decided to try the effect of large doses of vitamin C on the cataract. Beginning May 18 the patient began to drink 40 ounces of orange juice¹¹¹ daily and has continued thus since. Within twelve days perception of light became so sharp as to be annoying. June 26, additional vitamin C therapy was instituted in the form of crystalline vitamin C¹¹² (ten 50 mg. tablets daily). By July 4 the shiny hard pearliness of the left pupil had become much less marked. The dosage of the tablets was steadily increased until at present (October 1936) she is taking twenty-five 50 mg. tablets (1.25 Gm.) daily in addition to 40 ounces of orange juice daily (about 0.40 Gm. of vitamin C).

There has been a slow, but steady, improvement in both vision and the appearance of the pupil. The patient can now distinguish various colors and the blurred outlines of large objects. The pupil, which originally had a shiny pearl-like hardness, has now lost this appearance and seems to be semitranslucent. When dilated, the periphery of the pupil appears normal. To gross examination the cataract now appears variable in density, being roughly irregular in the temporal portion and much paler there. Slit lamp examination discloses that the anterior cortex, up to the nucleus of the lens, is transparent. The appearance of the lens otherwise is unchanged. There can be no doubt that definite improvement in this cataract has occurred. What the ultimate outcome will be is, of course, problematic as yet. The future course of this patient will be reported at a later date.

TOXIC REACTIONS

Special types of toxic reactions are described in their proper sections. There are certain types of reactions that have not received their proper attention in the literature. Four patients complained of marked languor and weakness. Of the four, one was a patient with hyperinsulinism whose blood sugar dropped below the premedication levels. Three patients felt drowsy and presented a "toxic" appearance, if one may be permitted the use of such an expression. They had no outstanding complaints but their appearance and clinical behavior became so rapidly worse that the drug had to be discontinued. One patient was prostrated for several days after ingesting one capsule. This happened twice, so that the drug had to be abandoned. One patient developed extreme generalized aches and pains after the ingestion of three capsules. The symptoms recurred after the drug was resumed.

Among other side actions noted were the development of an acute cystitis in one patient and marked dizziness in another, necessitating the withdrawal of the drug.

111. One one-hundredth gram of vitamin C corresponds to about 1 ounce of fresh orange juice.

112. The form used was Celbione, a preparation of Merck & Co., who cooperated in supplying the drug.

Colds and sinusitis developed in thirteen patients, in a few twice. Five patients developed acute bronchitis, two acute laryngitis, and three acute tonsillitis. The incidence of these infections of the upper respiratory tract was certainly no greater than would be the case in a control group, yet there is no gainsaying the fact that the excessive sweating, to which many patients are subject, does predispose to the development of colds. Noun's¹¹³ patient, who became sensitized to dinitrophenol and developed asthma, is worthy of note.

* Patients who did not receive dinitrophenol.

The patients included three with chronic arthritis and five with syphilis (including one with tabes). None suffered any ill effects except the one with tabes, who developed urticaria. Several patients were alcoholic addicts but showed no untoward reactions. Patients with renal damage also showed no unusual susceptibility to the action of the drug. Four patients with moderately advanced rheumatic heart disease (two with mitral stenosis) were included. The drug may be used apparently with impunity in such cases.

Seven fatalities have been reported, six from dinitrophenol and one from dinitro-orthocresol.¹¹⁴ Only two were definitely due to overdosage.¹¹⁵ One cannot refrain from remarking that, in view of the remarkably extensive use of the nitrophenols, often without medical supervision, fatalities are extremely rare.

RESULTS

Tainter, Stockton and Cutting³⁴ achieved weight reduction in 165 of 170 unselected obese patients. The average daily dose was 0.34 Gm. and the average weight loss 1.4 pounds (635 Gm.) a week (table 7, group 9). Others reported losses ranging from 0.92 to 1.7 pounds a week.¹¹⁶ In a review⁸³ of 290 cases in the literature, 276 showed a weight loss. Bayer and Gray¹¹⁷ found dinitrophenol to be an effective adjunct to diet, after the weight loss on diet alone had become stationary. Negative reports in the literature are few.¹¹⁸ Other reports show very disappointing losses of weight.¹¹⁹

In the present series the 181 patients were divided into several groups (table 7). When analyzed statistically, some surprising results are obtained. Fifty-nine patients were given dinitrophenol alone (groups 1 and 2). Of these, twelve (20.3 per cent) lost no weight. Forty-seven lost weight very satisfactorily, an average of 2.1 pounds (953 Gm.) a week. This compares with Tainter, Stockton and Cutting's³⁴ average of 1.4 pounds (635 Gm.) a week. Taken as a group, the average loss of weight for the patients on dinitrophenol (group 3) was 1.7 pounds (770 Gm.) a week. The percentage of failure is quite high compared with Tainter's percentage (only five of 170 lost no weight) and yet is more consistent with the fairly numerous failures of reduction reported in the literature. The dosage is not in question, as in an effort to secure weight loss the dose was raised considerably above that of the group which lost weight (3.9 mg. per kilogram in group 1 compared with 3.2 mg. per kilogram in group 2; in many patients the dose ranged between 5 and 6 mg. per kilogram without result).

In group 4, forty-one patients were given 2 grains (0.13 Gm.) of desiccated thyroid and the dinitrophenol dosage was raised enough to produce a satisfactory weight loss. In this group the average weight loss was the same as in group 2, and the dinitrophenol dosage was slightly higher. The chief difference was that all patients lost weight, as contrasted with a failure of 21 per cent in group 3. In group 5 (thirty-nine patients) the thyroid dosage was increased to from 3 to 4 grains (0.2 to 0.26 Gm.) daily. In spite of this increase and a fairly marked increase of dinitrophenol dosage the weight loss was distinctly lower than in either group 2 or group 4. Again there were no failures of weight reduction. In group 6 (which comprised a small group of patients resistant to ordinary dosage) the average loss of weight was the same as in the preceding groups, but the dinitrophenol dose reached was the highest in

TABLE 7.—Effects of Dinitrophenol and Desiccated Thyroid on Reduction of Weight

* Summation of groups 1 and 2.

the entire series. The thyroid dosage was also high. One patient, who had pituitary dysfunction, became refractory to thyroid after a dose of 9 grains (0.6 Gm.) daily was reached. The dose was steadily increased to 33 grains (2.15 Gm.) daily without any clinical effects whatever.

In group 7 (thirteen patients), each patient was given one 100 mg. capsule of sodium dinitrophenol daily, and the desiccated thyroid dose was regulated to yield a satisfactory loss of weight. In this group the best results of the series were obtained, the average loss of weight being 2.6 pounds (1,180 Gm.) a week. It must be noted, however, that the duration of treatment was

short, covering an average of three weeks, when patients lose weight most rapidly under any regimen of treatment.

Why the addition of moderate doses of desiccated thyroid (2 grains, or 0.13 Gm. daily) should enhance the action of dinitrophenol is a matter for speculation. Possibly the beneficial effect is due to the action of thyroid on the distribution of water in the body. Thus it tends to prevent the water-logging of the tissues, to which many failures of dinitrophenol therapy must be ascribed. Possibly a few patients in this group would have lost the same amount of weight without the presence of sodium dinitrophenol, even though no rigid dietary measures were followed. It will be noted in groups 2, 4, 5 and 6 that, as the thyroid dosage was steadily raised, a corresponding increase in the dinitrophenol dosage occurred, in order to produce comparable losses of weight. The significance of this is undetermined.

Dinitrophenol acts most satisfactorily in patients with the exogenous type of obesity. "Individuals with pituitary or gonadal gland deficiency often tolerate the drug badly or not at all."⁹ Its ineffectiveness in hypothyroid patients has been noted.¹²⁰ This tendency was also observed in the present series.

A group of twenty-two patients (group 8) were put on a regimen of a moderately restricted high protein diet (averaging 1,500 calories a day) abetted by desiccated thyroid. The dose was controlled by watching the pulse rate. The thyroid was discontinued or reduced when the pulse rate reached 100 a minute. It was controlled also, of course, by the development of nervousness, palpitation, substernal pressure or headache. The effect of thyroid is proportional to the dose. The average rate of weight loss was the lowest of all the groups (1½ pounds, or 680 Gm., a week). The thyroid dosage was moderate. This method of weight reduction is very satisfactory and easy to control. The results obtained may be compared with those of Lyon and Dunlop,¹²¹ who obtained an average daily loss of 273 Gm. on diet combined with thyroid as contrasted with 162 Gm. a day on diet alone. Patients with pituitary disease often show very little response to thyroid therapy. The weight loss in ovarian cases is markedly increased by thyroid.¹²² In group 8 were two patients with hypopituitarism: one did not respond to even a dose of 15 grains (1 Gm.) daily; the other patient lost 36 pounds (16 Kg.) in twenty weeks and then gradually became refractory to even 30 grains (2 Gm.) of desiccated thyroid daily for four months.

REPORT OF CASE

Mrs. M. T., aged 46, white, who weighed 310 pounds (140 Kg.), first began treatment Oct. 31, 1934. She concluded her treatment June 30, 1936, at which time she weighed 170 pounds (77 Kg.), a loss of 140 pounds (63.5 Kg.). She received treatment for eighty-four weeks (treatment being intermitted about every three months for one week). Her average rate of loss was 1.7 pounds (770 Gm.) a week. During her period of treatment she ingested a total of 254 Gm. of dinitrophenol with no ill effects whatever. The dose varied tremendously, the average being 0.5 Gm. daily. For three weeks she took 0.65 Gm. daily. Complete laboratory studies were negative throughout (urine, blood count, icteric index, van den Bergh test, bromsulphalein test, intravenous phenolsulfonphthalein test, dextrose tolerance test and electrocardiogram). She represents the largest loss of weight on dinitrophenol medication recorded in the literature.

COMMENT

In dinitrophenol the medical profession has acquired a remarkable drug, a metabolic agent that is well adapted to both clinical and laboratory research. The problems connected with its unpredictable, and occasionally alarming, reactions in some patients are far from solved. Apparently it is nontoxic to the liver, kidneys and heart in therapeutic dosage. Neutropenias are rare. Peripheral neuritis is rather common but not troublesome. Skin rashes, which are common, no longer excite their quondam fear. Cataracts, whether due to the direct effects of the drug or possibly to some unknown mechanism mediated by it, are common. No loss of weight can be condoned at the price of cataracts, and consequently the indiscriminate clinical use of dinitrophenol should be discontinued at once until the problem of complicating cataracts is solved. The clinical use of dinitrophenol should be reserved for urgent indications only.

CONCLUSIONS

1. One hundred and eighty-one unselected ambulatory obese patients were studied. One hundred and fifty-nine patients were given therapeutic doses, by mouth, of 2:4 sodium dinitrophenol alone or in combination with desiccated thyroid. Twenty-two patients were treated with dietary control and desiccated thyroid.

2. The therapeutic administration of dinitrophenol does not impair liver function (as disclosed by studies of the icteric index, van den Bergh test and bromsulphalein test), renal function (as disclosed by studies of the urine and the intravenous phenolsulfonphthalein test) or cardiac muscle (as disclosed by electrocardiographic tracings).

3. The pulse rate is unaffected by therapeutic dosage. There were two unusual cases of bradycardia. Ten hypertensive patients (including two who had chronic nephritis and one malignant hypertensive patient) showed marked prompt reduction of blood pressure. Normal blood pressure shows no significant change. One case of dinitrophenol phlebitis was observed. The drug can be used very satisfactorily in obese patients with rheumatic heart disease.

4. The dextrose tolerance studies in normal patients reveal that with short courses of dinitrophenol administration there is a moderate elevation of the fasting blood sugar (though not hyperglycemia) and a moderate impairment of dextrose tolerance in the majority of cases. With prolonged therapeutic administration there is no change in the fasting blood sugar and a marked increase in dextrose tolerance. In diabetic patients on short courses of dinitrophenol the results are variable, the dextrose tolerance being increased as often as decreased, with parallel changes in the fasting blood sugar. With prolonged administration in patients with diabetes there is an increase of carbohydrate tolerance.

5. Gastro-intestinal disorders are negligible.

6. The average increase in the basal metabolic rate is about 11 per cent for each 0.1 Gm. daily dose. No consistent effect of dinitrophenol on blood cholesterol was noted.

7. Skin rashes were observed in 20.1 per cent. Simple pruritus occurred in four cases, a macular rash in three, papular and maculopapular rashes in twelve, swelling and redness of the hands and feet in four, and urticaria in ten. A violent urticarial reaction was observed. A case of dinitrophenol alopecia was observed.

8. There is no way of predicting sensitivity to dinitrophenol. Skin tests are of no value. Dinitrophenol reactions are probably only rarely allergic in character.

9. Four patients developed marked peripheral neuritis. Five patients showed disturbances of taste that disappeared without omission of the drug.

10. No case of agranulocytosis developed nor were any changes noted in the blood cells, as shown by blood counts.

11. In a case of cataracts complicating dinitrophenol therapy, somewhat encouraging results were obtained with vitamin C therapy.

12. Other toxic side-actions, such as generalized pains and weakness, were observed.

13. With dinitrophenol alone, 20.3 per cent of patients (twelve of fifty-nine) lost no weight. The average loss of weight for the remainder (forty-seven patients) was 11.1 pounds per patient, with an average rate of weight loss of 2.1 pounds weekly. The addition of 2 grains (0.13 Gm.) of desiccated thyroid daily produced a marked increase in dinitrophenol effectiveness, no failure of reduction occurring in this group. The average weight loss in this group was 11 pounds per patient, with an average rate of loss of 2 pounds a week. The group treated with diet and desiccated thyroid lost an average of 15 pounds, with an average rate of weight loss of $1\frac{1}{2}$ pounds a week.

14. One patient lost 140 pounds (63.5 Kg.) in eighty-four weeks, an average of 1.7 pounds (770 Gm.) a week. During that time she took 254.6 Gm. of sodium dinitrophenol with no ill effects, as demonstrated by complete repeated laboratory and clinical studies.

15. The indiscriminate clinical use of dinitrophenol should be discontinued until the vexing problem of cataracts complicating dinitrophenol therapy is solved.

402 Spencer Street.

Clinical Notes, Suggestions and New Instruments

PRIMARY HEMATOGENOUS OSTEITIS OF THE PATELLA

F. L. FLACK, M.D., TULSA, OKLA.

Primary spontaneous hematogenous osteitis of the patella is evidently quite unusual, according to the reported cases in a review of the literature on this subject. Also the diagnosis of this condition is rarely made early enough to prevent marked destruction of the patella and an extension of the infection. Chesky¹ in 1923 made an extensive review and found thirty-five cases reported and added one of his own. Other cases have been reported by Christopher,² Dillehunt,³ Martin⁴ and Sagel.⁵ The following case is of unusual interest:

Mrs. M. Y., aged 20, was seen Dec. 28, 1936, at St. John's hospital. Examination showed the right knee and the region just above and below to be swollen to about twice the normal size. The swelling extended about 8 inches (20 cm.) above the knee and 2 or 3 inches (5 or 7.5 cm.) below. This area of swelling was red and painful, and the skin over the knee joint was darkly mottled. The extremity was fixed in extension and was very painful on flexion or extension. There was but slight pain on motion in a longitudinal direction. The swelling was tense and no fluctuation could be made out. The temperature was 102 F., pulse 120 and respiration rate 26. Physical examination was entirely negative in other respects. The white blood count was 8,150. The Kahn and Kline reactions were

negative. There was physical and laboratory evidence of a moderate secondary anemia. There was no evidence of tuberculous or gonorrheal infection.

X-ray examination of the region of the right knee showed marked absorption and osteitis, with many sequestrums involving the entire patella. All the other bony structures in the region of the knee joint were normal.

The patient gave a history of gradually increasing pain in the region of the right knee, which had started eight weeks previously. She had been treated during these eight weeks with various forms of therapy for variously named diseases. No history of trauma or local infection was obtained.

Under spinal anesthesia the knee joint was aspirated with a large bore needle and no fluid was found. An incision was made over the patella, and a large amount of pus, estimated at two thirds of a pint, was evacuated. The pus had extended into the prepatellar bursa and up the median side of the thigh a distance of 6 inches (15 cm.). The knee joint did not contain an increased amount of fluid. The patella was practically destroyed and all that remained was several sequestrums. The sequestrums were removed and drainage was established.

Microscopic examination of the pus and blood agar cultures showed numerous colonies characteristic of *Staphylococcus aureus* in pure culture. Microscopic examination of the sequestrums showed marked neutrophilic and round cell infiltration with much focal necrosis.

During convalescence repeated questioning disclosed no history of trauma or infection to the knee or any other part of the body. There was no history of any infection obtained. No doubt some infection in the throat or some part had been present.

Following the removal of the sequestrums and drainage she was immediately relieved of pain, and her general physical condition rapidly improved. The drainage continued for about five weeks. At this time, Feb. 20, 1937, the wound is closed, she has about 50 per cent motion of the knee, which is increasing, and she is walking with a slight limp and bearing weight on this leg.

816 National Bank of Tulsa Building.

Osteitis of the patella.

Weelum MacLure.—Stouten your hearts by reading of the doctor in fiction, and emulate Lydgate, at least up to the point which will warn you against marrying the wrong woman. Familiarize yourselves with the writings of healthy-minded doctors like Oliver Wendell Holmes and John Brown, of Rab and His Friends. If you need an antidote for the cynicism of Arrowsmith, buy or borrow Sarah Orne Jewett's nigh-forgotten story depicting her own father as a country doctor; for there are still John Leslies in the country districts and room for many more—plenty of room, too, for Nan; and if she is really serious about it she's worth to the world a thousand Leoras. Perhaps best of all, if you would learn what unalloyed professional devotion may be and what rewards it may bring, read or reread the last chapters of Ian Maclaren's *Beside the Bonnie Briar Bush* and let the example of Weelum MacLure, to whom I have already alluded, become a part of you.—Cushing, Harvey: *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

Special Article

DIPHTHERIA MORTALITY IN LARGE
CITIES OF THE UNITED
STATES IN 1936

FOURTEENTH ANNUAL REPORT

For the preparation of this annual review, data have been obtained from the health departments of the same ninety-three cities that have been considered in previous annual reviews on diphtheria death rates and likewise the same cities for which data were tabulated on typhoid.¹ The health officers were asked to furnish their own local estimates of population in view of the fact that figures for 1936 have not been released by the United States Census Bureau. In the case of Scranton, the figures were furnished by the Pennsylvania State Health Department. In a few instances in which the local health department did not furnish an estimate, the 1930 census figures were employed. It is believed that any reasonable corrections in population would not materially influence the rates.

As has been the case in previous articles, the health department was requested to report not only the total number of diphtheria deaths that actually occurred in the community but to indicate the number of deaths among nonresidents.

The fourteen New England cities (table 1) continue to have a good record, the death rate for the entire group being practically the same as for 1935. In each of the last two years there were twenty-eight deaths from diphtheria in this group. While for 1935 half of these cities reported no death from diphtheria, in 1936 there were only three cities (Cambridge, New Haven, Somerville) with no death; but there were three addi-

tional cities (Worcester, Bridgeport, Springfield) in which it is stated that all deaths occurred among nonresidents. Cambridge and New Haven have had no death from diphtheria during the past three years (table 10). Cambridge and Somerville reported no death from diphtheria or typhoid in 1936 (table 12).

The preceding articles were published in THE JOURNAL, Sept. 20, 1924, p. 918; April 25, 1925, p. 1269; April 3, 1926, p. 1005; April 30, 1927, p. 1396; May 19, 1928, p. 1621; May 25, 1929, p. 1759; June 7, 1930, p. 1838; May 23, 1931, p. 1768; May 7, 1932, p. 1644; May 20, 1933, p. 1595; May 26, 1934, p. 1758; June 15, 1935, p. 2182, and June 13, 1936, p. 2060.

1. Typhoid in the Large Cities of the United States in 1936, J. A. M. A. 108: 2118 (June 19) 1937.

Lowell, with a rate of 8.0 (table 1), not only had the highest death rate of any city in the group but also the highest death rate of any of the ninety-three cities (table 9). The death rate in this city has been relatively high for many years. With this one exception, no city in the group had a rate in excess of 2.0. Boston, the largest city, reported seven diphtheria deaths, of which two were in nonresidents.

There are eighteen cities in the Middle Atlantic states in which eighty-seven deaths from diphtheria were reported in 1936, a definite decrease from the 129

‡ Incomplete data.

§ Diphtheria data for Scranton furnished by Pennsylvania Department of Health, Harrisburg

deaths in 1935. The rate of 0.65 (table 15) is but two thirds of the rate for 1935. This group of cities had the lowest quinquennial average for 1930-1934 as well as the lowest rates for the past two years. While in 1935 there were three cities with a rate higher than 2.0 (Trenton, Camden, Jersey City), there were but two cities with rates above 2.0 in 1936 (Pittsburgh, Yonkers). Yonkers finds itself in the unenviable position of having both a high diphtheria (5.5) and a high typhoid (4.8) rate in 1936. This is quite in contrast to the low death rate reported in Yonkers since 1930. No comment is made by the health officer of any unusual outbreak. Eight cities reported no death from diphtheria in 1936. Syracuse has had no death in four consecutive years, Utica has been without a death during the past three years, and Albany, Erie and Rochester report no deaths in 1935 and 1936 (table 10). Syracuse and Utica have the distinction of being in the group of six cities (table 12) that report no death from diphtheria or typhoid in 1936. Among the largest cities, New York with thirty-five resident deaths records a new low rate (0.5). The rate is the same in Philadelphia (0.5), with ten resident deaths. Of ten deaths in Buffalo, five occurred among nonresidents. Of the sixteen deaths in Pittsburgh, two were of nonresidents. Of the nineteen cities with no diphtheria death in 1936, eleven are in the New England and Middle Atlantic groups (table 11). Of the six cities with no deaths from typhoid or diphtheria, four are in these two groups (table 12). Of the eight cities that have gone two or more years without a death from diphtheria, all except Tacoma are in the New England and Middle Atlantic groups (table 10).

The nine cities of the South Atlantic group record sixty-seven deaths, compared with eighty in 1935, a

rate in 1936 of 2.59. One city (Wilmington) reports no death in 1936. Five of the nine report rates in excess of 2.0. Atlanta and Washington have rates below that of the preceding year (table 3). Of twenty-seven deaths in Washington, nine were among non-residents; of five deaths in Richmond, three were among nonresidents. If correction for residence is made, the list of cities without a death increases to three with the addition of Miami and Tampa. Baltimore with ten deaths, two of which were of non-residents, shows an increase over 1935; however, this city continues to maintain a relatively good position in this division.

The cities in the East North Central states report 168 deaths compared with 236 in 1935 (table 15).

* All diphtheria deaths were stated to be in nonresidents.
† One third or more of the reported diphtheria deaths were stated to be in nonresidents.
Diphtheria deaths from Chapin's Municipal Sanitation.
Incomplete data.

The group rate of 1.73 is lower than that of 2.45 in 1935. Grand Rapids is the only city (table 4) with no death, although Milwaukee, Canton and Peoria record that all deaths were among nonresidents. For Milwaukee it is stated that two nonresident cases were brought into the city for hospitalization. There are but four cities of the eighteen which have a corrected rate in excess of 2.0. Evansville, at the top of the list in 1935 with no death, dropped nearly to the bottom in 1936 with a rate of 2.8, as a result of three resident deaths. Among the larger cities Chicago records eighty-seven deaths, all but one being residents; Detroit reports eighteen deaths, of which five are among nonresidents; Cleveland reports ten deaths, of which all are among residents. Of the eight deaths in Cincinnati, three are of nonresidents.

The six cities in the East South Central states have greatly improved their records over the preceding year, there being thirty-eight deaths in 1936 in contrast to fifty-nine in 1935 (table 15). Of these thirty-eight deaths fourteen, or 37 per cent, occurred among non-residents, again showing how these Southern cities

recorded as among residents. Of the seventeen deaths in St. Louis, three are of nonresidents and of the five in Des Moines, two are of nonresidents. Duluth seems to be holding its place as the leader in the West North Central group.

The eight cities in the West South Central group, while showing a decrease in the number of deaths from 108 in 1935 to eighty-seven in 1936, continue to have the highest rate for any section of the country (table

15). It is this same group of cities that records the highest death rate for typhoid. There is not a city in the group with a diphtheria death rate in 1936 below 2.0 (table 7). Dallas, with nineteen deaths, of which six are among nonresidents, has the highest rate. As in the case of the East South Central states, non-residence plays an important part, as evidenced by four nonresident deaths out of thirteen deaths in San Antonio and ten out of twenty in New Orleans. In Houston there is no separation by residence for the fourteen deaths from diphtheria. Of the five cities with the highest rate for 1936, two (Dallas and San Antonio) are in this group. Fort Worth and San Antonio show a noteworthy decrease in rate over the preceding year.

The Mountain and Pacific states record seventy-one deaths in 1936, compared with eighty-three in 1935 (table 15). As in the preceding year there are three cities with no deaths (table 8). In only one instance (Tacoma) has there been complete absence of deaths

for two consecutive years. Of the eleven cities there are but three with rates in excess of 2.0 and there are six cities with a rate less than 1.0. Oakland reports a noteworthy decrease from 5.7 to 1.0. Of forty-six deaths occurring in Los Angeles, seventeen were among nonresidents.

Of the entire ninety-three cities there were nineteen in 1935 with a rate of 5.0 and over (table 13). In 1936 there were but five cities in this class. The number of cities with no deaths from diphtheria was the

same each year, nineteen. There were, however, only eight cities (table 10) that were in this class for both years.

While no attempt has been made to determine the relationship between an active program of diphtheria prevention and the prevalence of this disease, the gen-

eral opinion gained by observation and knowledge of local circumstances leads inevitably to the conclusion that the preventive programs so extensively instituted throughout the country are resulting in a lower death rate from diphtheria.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

AT ITS 1936 MEETING THE COUNCIL DISCUSSED THE STATUS OF AMINO-PHYLLINE. AS A RESULT OF THE DISCUSSION THE COUNCIL VOTED TO CONTINUE RECOGNITION OF CLAIMS FOR THIS DRUG AS A MYOCARDIAL STIMULANT AND DIURETIC. THE COUNCIL DECIDED THAT THERE IS NO WARRANT FOR CLAIMS OF EFFICACY AS A DILATOR OF THE CORONARY ARTERIES OR OF USEFULNESS IN OVERCOMING PAIN IN CORONARY OCCLUSION OR ANGINA PECTORIS. AS A RESULT OF FURTHER CONSIDERATION THE COUNCIL VOTED THAT CLAIMS FOR ALL OTHER ACCEPTED XANTHINE DERIVATIVES BE SIMILARLY RESTRICTED AND THAT MANUFACTURERS OF ACCEPTED PRODUCTS BE NOTIFIED THAT AFTER OCTOBER 1 ALL ADVERTISING FOR SUCH PRODUCTS MUST CONFORM TO THESE LIMITATIONS.

THE COUNCIL FURTHER AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.

PAUL NICHOLAS LEECH, Secretary.

LIMITATIONS OF CLAIMS FOR AMINO-PHYLLINE AND OTHER XANTHINE DERIVATIVES

Few significant studies relating to the action of theobromine and theophylline preparations in cardiovascular disease have appeared since this subject was last reviewed.¹

Experimentally it has again been demonstrated that these substances cause dilatation of the coronary arteries in dogs² and in rabbits.³ In the latter the effect secured seemed to vary with the concentration of the drug, as it was noted that strong solutions of theobromine with sodium salicylate caused actual vasoconstriction while weaker concentrations produced the more usual vasodilatation. The dilator effect in intact dogs when theophylline ethylenediamine was given intravenously in doses comparable to those used clinically was found to last from six to forty-seven minutes, with an average duration of 21.6 minutes.^{2b}

A new experimental approach to a study of the vasodilator effect of these substances was devised by Fowler, Hurevitz and Smith,⁴ who noted the effects of theophylline with ethylenediamine on cardiac infarcts produced by ligating the coronary arteries of dogs. When the artery was tied, an area of cyanosis appeared corresponding to the infarcted area. If the drug was then given, the cyanotic area decreased in size. Furthermore, the resulting infarct was smaller in those animals which were treated with daily doses of the drug postoperatively before being killed. From these observations the authors concluded that "theophylline ethylenediamine promotes the development of the collateral circulation in experimentally induced cardiac infarction in the dog. The results justify the use of this preparation in the treatment of disease of the coronary arteries and acute coronary occlusion."

With these conclusions Wiggers and Green⁵ are in disagreement. These authors failed to detect significant changes in the inflow rate at high perfusion pressure before and after the use of drugs following experimental coronary occlusion in dogs; nor were they able to prevent contractile failure or to restore contractions to the ischemic area. The drugs used included theobromine and theophylline preparations. Summing up, the authors stated that "a sufficient sampling of possible

useful drugs by these methods necessitates, we regret, the conclusion that an increase in collateral circulation sufficient to be of functional use cannot be attained by use of vasodilating drugs after complete coronary occlusion."

Clinically the use of theobromine and theophylline preparations has continued to be widely recommended for the relief of such complaints as cardiac pain, cardiac asthma, paroxysmal dyspnea, Cheyne-Stokes respiration and intermittent claudication. For the most part these reports are uncritical and the observations are uncontrolled. No attempt will be made to review these papers here.

Two carefully controlled studies of the effect of drugs in reducing the frequency of attacks of angina pectoris have been made. In 1933 Evans and Hoyle⁶ reported their observations on the effect of thirteen drugs compared with a placebo on the frequency and severity of attacks in a series of patients with angina pectoris. The medications employed included sodium-theobromine, sodium salicylate and aminophylline. In summary the authors stated that "with one exception a measure of improvement appears to result from every remedy tried, and at least as great an improvement during treatment with placebo. This universal efficacy can only be explained by natural variations in the severity of the symptoms, which give a spurious value to each remedy. . . . We have been unable to convince ourselves that any drug tested is worthy even of trial in the routine treatment of the disease." A substantially similar study of theobromine and aminophylline has been made by Gold, Kwit and Otto,⁷ who concluded that "the xanthines exert no specific action which is useful in the routine treatment of cardiac pain."

The peripheral vasodilating effect of theobromine and its salts has been studied by measurements of the skin temperature under the necessary carefully controlled conditions. In fifteen patients with peripheral vascular disease, Newell and Allen⁸ found that theobromine with sodium salicylate produced an average rise of 1.8 degrees C. and that this lasted about two hours. They concluded that the drug was less effective than other measures but that it might be used as an adjunct to them. An essentially similar conclusion was reached by Scupham.⁹ More recently McGovern, McDevitt and Wright,¹⁰ giving large amounts of theobromine with sodium salicylate by mouth and by iontophoresis to patients with vascular disease of the extremities, found it to be a feeble and unreliable vasodilator and concluded that it was valueless in the treatment of peripheral vascular disease.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1937, p. 69.

The following dosage form has been accepted:

Ampoules Procaine Hydrochloride Solution 2%, 1 cc.: Each cubic centimeter contains procaine hydrochloride 0.02 Gm., sodium chloride 0.005 Gm., and distilled water to make an isotonic solution of 1 cc.

DIGIPOTEN (See New and Nonofficial Remedies, 1937, p. 192).

The following dosage forms have been accepted:

Digitoten Tablets 0.05 Gm. (3/4 grain): Each tablet contains 1/2 U. S. P. digitalis unit.

Digitoten Tablets 0.1 Gm. (1 1/2 grains): Each tablet contains 1 U. S. P. digitalis unit.

GASTRIC ACIDITY AND EXPERIMENTAL
ULCER

Recently evidence was discussed¹ in support of the view that ulcers produced in the gastro-intestinal tract of dogs by certain experimental procedures are due chiefly to the corrosive action of excessive amounts of free acid in the chyme. The increase in the free acidity of the gastric contents may result from either an increased secretion of acid, as some believe to be the case frequently in human ulcer, or from a decrease in the amount of available neutralizing alkali, particularly in the duodenum. The latter factor appears to be of primary importance in the production of ulcer in dogs by surgical procedures. It was stated also that within wide limits the concentration of pepsin appears of little importance, granted of course, that some of the enzyme is present.

Recently also further studies on ulcers produced surgically in the dog have been reported.² This work likewise serves to emphasize the etiologic importance of unneutralized gastric acidity in the production of this type of ulcer and the essential rôle of the alkaline duodenal secretions in the prevention of the lesion. In addition, the observations indicate that there are differences between the efficacy of the bile, of the pancreatic juice and of the secretion of the duodenum itself in inhibiting ulcer formation. Sixty healthy dogs were used in the investigation. The pylorus was severed and the gastric and duodenal ends were closed; continuity of the gastro-intestinal tract was then reestablished by an anterior gastrojejunostomy. The animals were divided into four groups, one of which, consisting of twenty dogs, served as controls. In a second group of ten dogs the accessory pancreatic ducts were ligated and severed and the main pancreatic duct was transplanted into the terminal portion of the ileum. In a third group of twenty dogs the common bile duct was transplanted into the ileum, and in the fourth group both the main pancreatic duct and the bile duct were transplanted into the ileum. Thus the experimental animals differed in only one respect, namely, the presence or absence of bile or pancreatic juice in the duodenum, and hence the contact of these fluids with the gastrojejunal anastomosis.

In the control animals in which only a gastrojejunostomy was performed, typical subacute and chronic ulcer formation was observed near the gastrojejunal anastomosis in 50 per cent of the animals. Ulcers developed in the same location in 70 per cent of the dogs in which the pancreatic duct alone was transplanted, in 90 per cent of those in which the common bile duct alone was transplanted, and in 100 per cent of those in which both the pancreatic and common bile ducts were transplanted. These observations again emphasize the

importance of the alkaline duodenal fluids in inhibiting the development of experimental ulcers of this type and, in addition, appear to warrant the conclusion that, "of all the constituents of the alkaline duodenal juices, bile has the most significant and effective influence in preventing the formation of jejunal ulcer; the duodenal secretion, the succus entericus, is the least important, and the pancreatic juice is midway between the two in this respect." These results add further to the growing mass of evidence that the amount of free acid present in the gastric chyme is a primary factor in the etiology of at least the experimental type of ulcer of the gastro-intestinal tract.

TEST TUBE SYNTHESIS OF SPECIFIC
ANTIBODIES

A quarter of a century ago Carrell and Ingebrigsten¹ of the Rockefeller Institute reported that fragments of guinea-pig bone marrow (or lymph glands) suspended in homologous blood plasma will form specific hemolysins against goat erythrocytes if these foreign red blood corpuscles are added to the culture medium. This apparent test tube synthesis of specific antibodies was consistent with the generally accepted side chain theory of immunity, which was not seriously challenged at that date. Many immunologists were skeptical, however, of the reported results. In attempting to confirm this alleged test tube production of specific antibodies, Kuczynski, Tenenbaum and Werthemann, Sato, Kimura, Bloom and a half dozen others failed.² Sato could find no trace of antibody synthesis in his tissue cultures. A few of his cultures did show traces of apparent antibody production, titers as high as 1:16 being obtained, for example, with 1:4 titers in his control tubes. (Serologic titers of 1:40,000 or even 1:100,000 are readily obtained in intact animals.) Recent experimental studies by Salle and McOmie² of the University of California have led to the quite definite conclusion that "neither precipitins, agglutinins nor hemolysins are produced as a result of the addition of homologous antigens to tissue cultures." The tissues tested by the California investigators were splenic, pulmonary and bone marrow explants from embryonic chickens, guinea-pigs and rabbits.

Several investigators have modified the original Carrel-Ingebrigsten tissue technic. Ludke, Kuczynski, Tenenbaum and Werthemann, for example, injected rabbits and guinea-pigs intravenously with large doses of killed bacteria and made explants from the spleen or bone marrow of the injected animals. These explants contained numerous phagocytosed bacteria. After five days' incubation the antigen laden explants yielded no traces of specific bacterial agglutinins. Przygode,

Reiter, Meyer and Loewenthal, and Sato, in contrast, obtained positive evidences of specific agglutinin production by this technic, titers as high as 1:160 being reported in Sato's papers.

Since all this conflicting evidence was obtained by application of the earlier, relatively crude, methods of tissue culture a reinvestigation of the entire problem seemed desirable. Landsteiner and Parker² of the Rockefeller Institute therefore transplanted fragments of adult rabbit spleen into the most favorable modern tissue culture medium thus far developed. This medium consisted of three parts of normal (autogenous) rabbit serum, one part of isotonic sodium bicarbonate (1.4 per cent) and two parts of Tyrode's solution containing four times the usual amount of dextrose, to which was added 0.005 per cent of phenol red to serve as an indicator. Each flask was supplied daily with an atmosphere consisting of 80 per cent oxygen, 8 per cent carbon dioxide and 12 per cent nitrogen. This medium and method of cultivation preserves a splenic fragment in a high degree of functional activity without stimulating excessive proliferation of its cytologic elements.

The New York investigators found that fragments of adult rabbit spleen removed from the animals two to three days after intravenous injections with guinea-pig erythrocytes almost invariably produce hemagglutinins for guinea-pig red blood corpuscles, titers often reaching 1:320. Control tests with duplicate cultures kept at 4 C. showed no hemagglutinin production. The New York investigators, however, were surprised to find that under the same cultural conditions splenic fragments taken from rabbits injected from one to twenty-four hours previously failed to produce demonstrable antibodies. This indicates that the production of antibodies by splenic explants depends on certain preparatory adaptations occurring in intact animals, which reactions are not completed till the second or third day after intravenous injection of a given antigen. Spleens taken from animals injected twenty-four hours previously and cultivated in fully prepared serum (i. e., serum taken from control rabbits injected three days previously) also yielded negative results. This indicates that serologic preparation or adaptation alone is not sufficient to insure *in vitro* antibody production. The fixed tissues themselves must apparently undergo a supplementary *in vivo* preparation. Parallel injections with nonviable bacterial antigens (e. g., *Vibrio metchnikovii*) confirmed these conclusions.

The authors conclude that, "in view of the positive results obtained when the antigen was allowed to remain from two to three days in the [intact] animal, the negative results obtained when this period was shortened . . . antibody production [must be a much] more complicated process than is usually assumed." No new theory as to the nature of this preliminary *in vivo* preparation of serum and fixed tissue cells, however, is

suggested by these authors. In the light of their results, however, the recently alleged neurologic integration of antibody-producing tissues (or functions) seems worthy of detailed investigation.

SUPERVITAMINOSIS AND TUBERCULOSIS

Much of the present-day commercial exploitation of vitamins and vitamin-rich foods is based on a belief that excessive intakes will increase the resistance of normal persons to microbic infections. Abundant experimental evidence supports the view that prolonged vitamin deficiencies do decrease antimicrobial resistance, but the data regarding the immunologic effects of superabundant vitamins are inadequate. An experimental study of the possible immunologic benefits of superfluous vitamin C has been reported by Heise and Martin¹ of the Trudeau Sanatorium.

Fifteen normal guinea-pigs were fed a stock ration consisting of carrots, hay, lettuce and oats. Five animals were used as controls and were not given additional vitamins. The other ten were given each a daily intra-abdominal injection of 20 mg. of crystalline cevitamic acid in the form of a neutral salt. After a seven day period, both control and vitamin-treated animals were injected with 300,000 tubercle bacilli into the groin. The daily injections of vitamin C were continued in the test group for five more months. No differences were noted in the two groups. At the end of this period one of the control animals died. All the remaining animals were then killed and necropsies performed.

The degree of tuberculosis in each animal was estimated on the basis of a possible maximum 4+ for each organ: lungs, spleen, liver and lymph nodes. Averaging the results gave a severity of 3+ for the control animals and of 2.2+ for the vitamin-treated group. Enlarged inguinal glands with marked caseation were found in both. The spleen was enlarged in both and thickly studded with tubercles, as was the liver. The lungs were involved to a lesser extent in both the treated and untreated groups.

Those observations were interpreted as establishing the fact that no significant differences exist between the extent and spread of experimental tuberculosis in guinea-pigs on a normal diet and in those having an excessive intake of cevitamic acid. Two possible criticisms of the experimental methods were recognized: The relatively large dose of tubercle bacilli might have masked slight differences in resistance, or undetected differences might have been shown by a study of the survival time, provided a sufficiently large number of animals for statistical reliability had been available. The results, nevertheless, are interesting because of their failure to demonstrate any experimental support for excessive vitamin C administration in tuberculosis.

Current Comment

COORDINATION OF ARMED AND CIVILIAN MEDICAL SERVICES

There seems at this time to be but little evidence that pacifism is gaining or that the campaign against wars is making appreciable progress throughout the world. It is more difficult, says Armstrong¹ in a recent article on this subject, for the civilian physician than it is for a member of the naval or military medical services to contemplate war. If war does come, medicine or the lack of it will, as it always has, play an extremely important part in the outcome. In past centuries, indeed, the lack of adequate medical service has destroyed more armies than have been destroyed by armed forces. While in the last war this was no longer true, medical preparedness must recognize the fact that future wars will not be waged exactly like the last one. The element of surprise and the unpreparedness of the defender play an important part in the medical problems of any nation. Moreover, it is already clear that in future conflicts civilian populations will suffer severely either directly or indirectly. Poison gases and demolition bombs, which are the two most effective weapons of bombardment aviation, will probably be utilized to a great extent; hence civilian physicians become immediately as important as members of the regular medical services. Armstrong recommends therefore that civilian physicians prepare themselves for wartime rôles by enlistment in the active reserves or by individual efforts to coordinate the work of the two branches of medicine. The latter objective can best be obtained through the medical and dental schools, the local and state health boards, the medical societies, special organizations, the Veterans' Administration, the U. S. Public Health Service and the organized reserves and National Guard.

NEUROGENIC THEORY OF ANAPHYLAXIS

Earlier immunophysiology assumed that allergic and immune reactions are initiated by the central nervous system or at least mediated through it. Recently Metalnikov¹ of the Pasteur Institute, Paris, reasserted his belief that in immunizing laboratory animals we are immunizing principally a hypothetic "immunity center" in the central nervous system, which in turn "directs the sensitivity of peripheral tissues." From this theory several European clinicians have concluded that therapeutic blockade or surgical interruption of the connection of the "immunity center" with peripheral tissues would prevent anaphylactic reactions in these tissues. Such a blockade has been attempted by alcohol injections² and by regional sympathectomy.³ Most immunologists are convinced that local anaphylaxis is wholly independent of central nervous connections. Ajo and Arthus⁴ of the Laboratory for Organotherapeutic Research, Garches, France, for example, have recently retested this belief so far as it relates to the local

anaphylactic reaction technically known as the Arthus phenomenon in rabbits. First they studied the effects of unilateral resection of the sciatic nerve in hypersensitive rabbits. They found that the Arthus reaction takes place with the same promptness and severity in the leg thus deprived of all sensory, motor and "trophic" connection with the central nervous system as in the control leg. To test the effects of sympathetic innervation, these investigators removed the left cervical ganglion in hypersensitive rabbits, causing sympathetic paralysis of the left ear. Both ears were then tested by subcutaneous injection with the same dose of specific foreign protein. The Arthus phenomenon occurred with equal promptness and equal severity in the two ears, the only observed difference being a slightly more rapid recovery on the sympathectomized side, presumably because of the hyperemia and hyperthermia of the paralyzed ear. The authors do not assume that this slightly accelerated rate of recovery is of practical clinical significance.

THE HYPOPHYSIS AND IMMUNITY

Clinical observation has suggested a relationship between hypophyseal function and immunity, characterized, for example, by a statistically subnormal antimicrobial resistance in acromegaly and an increased resistance in Cushing's disease.¹ Experimental confirmation has been recently reported by Churg² of the Institute for General and Experimental Pathology, Vilna, Poland. Confirming the previous investigations by Druckrey,³ he found that daily intravenous injections of the gonadotropic substance from human pregnancy urine were without apparent effects on the blood coagulation time of male rabbits. In normal female rabbits, however, the same substance caused a transient decrease in blood coagulability followed by shortening of the coagulation time. The increased coagulability persisted for several weeks after cessation of the injections. No similar results were observed in parallel tests of ovariectomized female rabbits. Females given daily subcutaneous or intravenous injections had an initial 100 per cent increase in serum complement titer, followed by a fall to about 50 per cent of the normal. This subnormal titer persisted for several weeks after cessation of the injections. No effects were demonstrable in the complement of male rabbits or in ovariectomized females. Churg concluded that the gonadotropic substance of pregnancy urine acts indirectly on the serum through stimulation of the female sex glands. Partial confirmation of this view was obtained by the injection of estrogen into ovariectomized females, which caused typical fluctuations in blood coagulability and complement titer. Progesterin injections, however, were without demonstrable effect. Churg's tentative explanation of the observed effects is based on Fuchs's⁴ theory of the identity of prothrombin and "komplementmittelstück." The greater the extent of transformation of prothrombin into thrombin, the less prothrombin is available for complement action.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE EIGHTY-EIGHTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 7-11, 1937

(Continued from page 2145)

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, June 8

The House of Delegates was called to order at 9:45 a. m. by the Speaker, Dr. Nathan B. Van Etten.

Roll Call

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. William D. Johnson, New York, and carried, that the House dispense with the roll call.

Presentation of Minutes

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. A. T. McCormack, Kentucky, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Credentials

Dr. Benjamin F. Bailey, Chairman, reported that additional delegates had been registered since the previous report of the committee, making a total registration of 165. He requested several members of the House who had not signed attendance slips to do so immediately.

Report of Board of Trustees

Dr. Austin A. Hayden, Secretary of the Board of Trustees, presented the following report of the Board, which was adopted on motion duly made, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried:

Resolutions Recommending Establishment of Council on Medical Ethics and Economics introduced by Dr. Carl F. Vohs, Missouri: The Association already has a Bureau of Medical Economics and a Judicial Council. The Board of Trustees suggests that, if the changes outlined in the resolutions are desired, suitable amendments to the Constitution and By-Laws should be introduced in the prescribed manner.

Resolution on Production of Educational Films introduced by Dr. C. A. Dukes, California: The Board has already studied the question of the education of the public with motion picture films and will be glad to give consideration to future needs in this respect as they arise.

Resolution on Program of Public Education introduced by Dr. Fred Moore, Iowa: Here again the Board would report that it has given long and earnest consideration to the development of a program of public education. The Bureau of Health and Public Instruction has developed an extensive program for the education of the public, and its efforts along this line have been approved by the House of Delegates. The Board of Trustees will be glad to give consideration to further development of this plan as the need arises.

Resolution on Investigation into Conduct of Magazine *HYGEIA* introduced by Dr. Walt P. Conaway, New Jersey: The Board would report that it has constantly endeavored to guard against the abuses recited in this resolution. It has ever been the policy of *HYGEIA* to instruct the public in sound medical science and particularly as to the value and importance of the physician in procuring suitable medical care. The Board is glad to take this opportunity again to reiterate its policy in this respect.

Resolution on Review of Motion Picture Films introduced by Dr. Thomas P. Farmer, New York: The Board of Trustees respectfully suggests that it has established in the headquarters office a Bureau of Exhibits which has available information concerning scientific films of value for those wishing such information. In cases in which films are used to

exploit medicaments or physical apparatus, the Council on Pharmacy and Chemistry and the Council on Physical Therapy may be asked for an opinion concerning the products mentioned.

Resolutions on Presentation of Exhibit of the American Medical Association at San Francisco International Exposition introduced by Dr. Elbridge J. Best, California: As plans become more mature, the Board of Trustees will gladly consider the cost and the advisability of an exhibit at the San Francisco International Exposition as these matters are presented.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Floyd S. Winslow, Chairman, presented the following report:

REPORT OF BOARD OF TRUSTEES

1. Dr. Charles Gordon Heyd, President: Your committee joins with the Board of Trustees and the Members of the American Medical Association in regretting the untimely death of Dr. James Tate Mason, President of this Association. It approves the action of the Board of Trustees in electing as President the Vice President, Dr. Charles Gordon Heyd, and it commends Dr. Heyd for his faithful performance of the many presidential duties during the past year.

2. Business Operations: The increase in gross earnings and miscellaneous income and the increase in expenditures for wages, salaries and other items reflect the widening of the activities of the Association in advancing the interests of its membership and meets with the approval of this committee.

3. Building and Equipment: Additions to building and equipment have kept pace with the increased demands of the work of the Association and are approved of by this committee, which furthermore approves of the contemplated additions to the equipment.

4. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION: Your committee congratulates THE JOURNAL on maintaining its leadership in its field of medical publication. It commends the management of THE JOURNAL for its foresight in the publication of "The Pharmacopeia and the Physician." It feels that this department has been serviceable to the membership and is in favor of the cooperation existing between THE JOURNAL and the United States Public Health Service in the work on venereal diseases. It is also in favor of the work of THE JOURNAL in the correspondence with other countries on the subject of economic and social relations of medical practice and commends the intensive development of the Department of Queries and Minor Notes and the efforts put forth to maintain high standards in medical education and practice.

5. Special Journals: The publications covering dermatology and syphilology, neurology and psychiatry, pediatrics, internal medicine, surgery, pathology, ophthalmology and otolaryngology are of the highest character and should be sources of great pride to the Association and to the respective specialties because of their completeness, usefulness and the clean character of their advertising pages. The growing competition in these fields of other journals by commercial concerns not maintaining advertising standards comparable to those of the periodicals of this Association is viewed with genuine alarm, since subscription support is thereby withdrawn in some measure from these journals. This is particularly noticeable in one periodical formerly published at a profit and now at a marked loss. At the present time your committee has reason to believe at least one certain specialty whose periodical is now operating at a loss contemplates the launching of a new journal to be pub-

lished by a commercial house. Your committee feels that this is most regrettable and whole-heartedly agrees with the Board of Trustees in issuing its warning that if the members of the specialties do not give their whole-hearted support to their journals it may become necessary to consider seriously the advisability of suspending publication of those special journals responsible for the large part of the losses incurred.

6. **HYGEIA:** Your committee feels that *HYGEIA* furnishes a constant and valuable source of information to its readers. The financial loss to the Association through the publication of this periodical in 1936 was less than half the loss during 1935. Your committee recommends that the publication of *HYGEIA* be continued.

7. **The Library:** Your committee recognizes in the Library one of the vital activities of our organization. It approves the provision of larger quarters for the Library and for increased activities in this department.

8. **Cooperative Medical Advertising Bureau:** Your committee is glad to note the wide support this bureau is receiving from the majority of the constituent medical associations and recommends that other state journals take steps to ally themselves with this department.

9. **Division of Food, Drugs and Physical Therapy:** Your committee commends the formation of this division and the creation of a committee on policy representing the three councils and believes that this plan will increase the efficiency of the work of these councils.

10. **Council on Pharmacy and Chemistry:** Your committee views with interest the ever increasing work of the Council on Pharmacy and Chemistry; it feels that this council renders valuable service to our membership by its investigations, and it recognizes the difficulties in connection with the selection of names for newly discovered therapeutic agents, particularly in the nomenclature of endocrine principles. Your committee is sensitive to the value of the work done on investigation of catgut sutures and nonspecific protein therapy. It approves the efforts of the Council and recommends that they be continued. This council deserves and should have the whole-hearted support of the medical profession in its efforts to maintain rationalism in the field of therapy.

11. **Council on Physical Therapy:** Your committee feels that one of the most important functions of the Association is the investigation and publication of reports on the use of physical therapy apparatus by this council. It also looks with favor on the educational activities of this council in its work with our constituent state and component county societies, whose members have received information of value by this means.

12. **Council on Foods:** Your committee feels that the efforts of this council tend to maintain high standards for food products and also improvement in the nature of advertising them. The reports on the nutritional significance of various classes of foods are of value to the general practitioner of medicine. During the past year the reports on the vitamins have been especially helpful.

13. **Chemical Laboratory:** The work of this laboratory continues to be of great value to our organization from the standpoint of its independent investigations and investigations of matters referred to it by the Council on Pharmacy and Chemistry and the Bureau of Investigation.

14. **Bureau of Investigation:** Your committee feels that the Bureau of Investigation has been of important assistance to the federal government and to better business bureaus and urges the continuance of this department.

15. **Bureau of Exhibits:** Your committee emphasizes the desirability of the continuance of the work of the Bureau of Exhibits in cooperation with the work of the Committee on Scientific Exhibit.

16. **Extension of Medical Service to the Indigent:** Your committee approves the attitude of the Board of Trustees in announcing its willingness with other organizations to make plans for providing medical service to the indigent.

17. **Motion Picture on Syphilis:** Your committee feels that the cooperation of the American Medical Association with the United States Public Health Service for better control of venereal disease is desirable.

18. **Report of the Committee to Study Air Conditioning:** In view of the importance of further study of air conditioning your committee recommends that the investigation of this committee be continued.

19. **Report of the Committee on Asphyxia:** Your committee recommends that the report of the Committee on Asphyxia be accepted and that the power requested be granted, with the exception that there be omitted from the report the following: "Your committee suggests the desirability of taking over the work and carrying on the program initiated and maintained for the last four years by the Society for the Prevention of Asphyxial Death. Informative material accumulated by this organization might be filed by the committee for the use of the Association and contacts with organizations and groups interested in the prevention of asphyxial death may be preserved and developed."

REPORT OF SECRETARY

The lucid report of our ever faithful Secretary deserves hearty commendation. The disparity that exists between "members" and "Fellows" suggests the wisdom of frequent appeal to "members" to become "Fellows," in order to increase the solidarity of our organization.

Substitution of the Organization Section of *THE JOURNAL* for the *BULLETIN* should be continued for another year to determine whether the new order of publication will fulfil its purpose.

The Annual Conference of Secretaries of Constituent State Medical Associations is indorsed. In event of an expectant absence of a state secretary from these gatherings, provision should be made to send the duly authorized alternate, as the loss to a given state society cannot be atoned for until the following year. Agenda could readily include topics for discussion, not fully decided by the House of Delegates, thereby paving the way for future action by the House.

The untiring work of the Secretary and his personnel in maintaining personal relation with county societies and with the humblest members of the American Medical Association serves to exemplify the finest traditions of our organization and your committee hereby commends our Secretary and his assistants on the completion of another successful year's work for our membership.

Respectfully submitted.

FLOYD S. WINSLOW, Chairman.
ARTHUR C. MORGAN.
C. L. CUMMER.
J. F. SILER.
MCLAIN ROGERS.

On motions duly made, seconded and carried, the report of the reference committee was adopted section by section and as a whole.

Invitation to Hon. J. Hamilton Lewis

Dr. W. C. Woodward, Director, Bureau of Legal Medicine and Legislation, reported that in accordance with instructions he had communicated with Hon. J. Hamilton Lewis, United States Senator from Illinois, who stated that he would be glad to appear before the House of Delegates on Thursday or Friday, June 10 or 11.

After discussion of a motion to invite Senator Lewis to appear before a special session of the House on Thursday morning, June 10, the matter was referred to the Reference Committee on Executive Session.

Report of Reference Committee on Reapportionment

Dr. Walter F. Donaldson, Chairman, presented the following report, which was adopted on motion of Dr. Donaldson, seconded by Dr. H. B. Everett, Tennessee, and carried:

The present apportionment of delegates is on the basis of one delegate for each 775 members or fraction thereof. Each constituent association is represented by at least one delegate irrespective of the number of members.

The By-Laws specifically provide that the total membership of the House of Delegates shall not exceed 175. The total membership of the Association on April 1, as recorded in the office of the Secretary, was 105,460.

An apportionment on the basis of one delegate for each 800 members would produce a total of 178 delegates, three more than are permitted by the By-Laws.

On the basis of one delegate for each 825 members, the total membership of the House would be 174, which is two more than the present membership. On this basis, Massachusetts and the Philippine Islands would each gain one delegate, New York would gain two delegates, and Missouri and Oklahoma would each lose one delegate.

On the basis of one delegate for each 850 members, the total membership of the House would be 170. On this basis, New

Number of Delegates Based on Different Ratios

State	Number of Members, 4/1/37	Bases of Apportionment and Number of Delegates Under Each	
		825	850
Alabama.....	1,472	2	2

United States Public Health Service.....	257	1	1
1 for each Scientific Section.....	95	1	1
		15	15
		174	170

The total voting membership of the House of Delegates shall not exceed 175.

York and the Philippine Islands would each gain one delegate, while Missouri, Oklahoma, Tennessee and Texas would each lose one.

The committee recommends that the apportionment of delegates for the next three years be made on the basis of one delegate for each 825 members or fraction thereof. Each state medical association, irrespective of the number of members, no matter how small its membership may be, is entitled to one delegate. On this basis, the membership of the House will be 174.

Respectfully submitted.

WALTER F. DONALDSON, Chairman.
H. B. EVERETT.
CHARLES J. WHALEN.
N. B. VAN ETEN.
OLIN WEST.

Report of Reference Committee on Sections and Section Work

Dr. James E. Paullin, Chairman, presented the following report:

Mr. Speaker and Members of the House of Delegates:

1. Your Reference Committee on Sections and Section Work has studied with interest and pride the report of the Council on Scientific Assembly.

Your committee commends the activity of the Council for the meticulous care used in the selection of subjects and the preparation of the program which has been furnished for the general scientific sessions and for the various section meetings. Such a well balanced program evidences the general interest of the Council in stimulating and advancing medical science and supplying useful and timely information.

2. Perusal of the program of the Scientific Assembly gives evidence of the importance of the scope and range of the activities of the Council in furnishing this short postgraduate course of instruction in general medicine, surgery and the various specialties. One is impressed with the fund of information available in the various sectional and general meetings.

3. In particular, your committee commends the innovation this year of a division of the general sessions program on Tuesday into a section devoted to the discussion of general medical topics and a section devoted to a discussion of outstanding surgical problems. Such a division gives promise of increasing the function of the general sessions within the time normally allotted the scientific program.

4. In view of the recent nation-wide interest manifested in venereal diseases, your committee commends the Council on Scientific Assembly for presenting a Symposium on Syphilis.

5. Your committee again calls attention to the wealth of material available in the Scientific Exhibit. A study of the Exhibit offers an easily assimilable summary of the present day advances in medicine and surgery.

6. Referring to the comments of the Council on Scientific Assembly concerning a proposed change in the By-Laws of the American Medical Association, namely, section 13, chapter XIV: "A Fellow shall present no more than one paper at any Scientific Assembly," a study of the minutes of the 1936 session of the House of Delegates reveals that no such amendment to the By-Laws was offered for consideration. Your committee believes that the purpose of the suggestion previously made was to give an opportunity to a greater number of Fellows to appear on the program of the sections. Your committee strongly urges that in the preparation of section programs the name of a Fellow either to present or to discuss a paper appear only once. This has no reference to the general scientific program.

7. The resolutions from the Section on Obstetrics, Gynecology and Abdominal Surgery request a change in name of a section which would necessitate a change in By-Laws and is without the jurisdiction of this committee. Your committee recommends that the resolutions be referred to the Council on Scientific Assembly for action, with the recommendation from this committee, however, that the request of the section be granted.

Respectfully submitted.

JAMES E. PAULLIN, Chairman.
ARTHUR J. BEDELL.
ELBRIDGE J. BEST.
CHARLES R. SCOTT.

On motions of Dr. Paullin, duly seconded and carried, the report of the reference committee was adopted section by section and as a whole.

Report of Reference Committee on Hygiene and Public Health

Dr. James Q. Graves, Chairman, presented the following report:

1. Resolutions on the Family Physician and the School Child introduced by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology: Your committee has carefully considered these resolutions and with the approval and consent of

Dr. Shurly, who introduced them, submits the following substitute resolutions:

WHEREAS, The family physician has labored for these many years without full recognition of his valuable services; and

WHEREAS, The various school systems of the United States depend on the family doctor for the prevention and diagnosis of disease and the protection of the public; therefore be it

Resolved, That the school boards and authorities in charge of the school systems all over our country be respectfully requested to enter and file on the index card of every school child the name and address of the chosen family doctor; and be it further

Resolved That the designated family doctor, together with the parents or guardians of the child, be informed by the proper school authorities of any accident or illness that may befall the child in the schools of this country; and be it further

Resolved, That it be recommended to the school authorities that the regular physical examinations of school children be made by the family physician whenever the parents desire, on forms provided by the school or health authorities, and that these examinations be accepted by the public authorities in lieu of examinations made by the school physician; and be it further

Resolved, That it be recommended that all records of health examinations accompany the scholastic record of the child as he passes from grade to grade; and be it further

Resolved, That the provisions of these resolutions be brought to the attention of the secretary of each state medical society and that he in turn inform the secretary of each local medical society.

2. Resolution on Importance of Preventive Medicine presented by Dr. Terry M. Townsend, New York: Your committee has considered this resolution and recommends its adoption.

3. Report of Board of Trustees on Motion Picture on Syphilis: Your committee has read the report of the Board of Trustees concerning the Motion Picture on Syphilis as printed on page 110 of the Handbook and recommends the adoption of the report.

JAMES Q. GRAVES, Chairman.

L. B. BATES.

W. F. DRAPER.

MEREDITH MALLORY.

G. H. MUNDT.

Section 1 of the report of the reference committee was referred back to the reference committee for a subsequent report, on motion of Dr. H. A. Luce, Michigan, seconded by Dr. George M. Fisher, New York, and carried.

On motions, duly seconded and carried, the second and third sections of the report of the reference committee were adopted.

It was moved by Dr. Graves, seconded by Dr. A. T. McCormack, Kentucky, and carried, that the report be adopted as a whole, with the exception of the first section, which had been referred back to the committee.

Report of Reference Committee on Medical Education

Dr. F. S. Crockett, Chairman, presented the following report:

REPORT OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Your Reference Committee on Medical Education, having read the report in the Handbook, and supplementary reports, wishes to commend the Council on Medical Education and Hospitals for its splendid work as evidenced by the marked improvement in the facilities of medical schools and the higher standards obtained for medical education.

Special attention is directed to the report on those schools giving only the first two years of basic medical sciences. While improvement of these schools has shown commendable progress, yet the problem of transferring from a school of basic medical science to a clinical school for completion of a medical education presents increasing difficulties and is a matter of serious concern to prospective medical students.

The annual census of hospitals met with response from 96 per cent of those registered. It is of interest to learn that, while only 939 hospitals are approved for internship and residencies, these approved institutions accommodated more patients than the 5,250 hospitals that are registered but not approved for intern training.

Attention is also called to the 3,612 hospitals existing in this country not approved by the Council or by the College of Surgeons. Your committee urges that some way be found to inspect and grade these institutions in the interest of the public welfare.

It is encouraging to learn that the Board of Trustees has authorized additional assistance to the Council for inspection. Another point of interest shown by the report is the commendable improvement in the percentage of necropsies stimulated largely through the activities of the Council. In 1926 only 249 hospitals were able to report 15 per cent or more of necropsies, while nine years later, 1935, some 692 hospitals had attained this average. Too much stress cannot be placed on the necropsy because of its educational value.

Your committee notes that a revised list of "Approved Colleges of Arts and Sciences and Junior Colleges" has been published this year. It is the opinion of your committee, however, that in at least some colleges premedical students should be afforded better actual medical contacts. Your committee would urge that the premedical adviser in each college offering a premedical course keep in close touch with the Council on Medical Education and Hospitals.

The report properly directs attention to the overcrowded conditions existing in mental hospitals. It is of especial interest to note that there is a definite relationship between overcrowding and the discharge and parole rate, showing a definite advantage in psychiatric treatment in those institutions in which sufficient space and adequate facilities are provided.

To give the Council time for further study of the five year period of training now required for certification by the specialty boards, your committee approves the proposed extension to Jan. 1, 1942, of the date on which this requirement becomes effective.

Your committee approves the Council's proposed study of graduate medical education now in process of formation. The evident advantage of well organized and wisely planned methods of making available to the practicing physician the latest developments of medical science must be obvious to all.

RESOLUTION REQUIRING PHYSICIANS ON STAFFS OF ACCREDITED HOSPITALS TO BE MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The idea underlying the resolution introduced by Dr. John Z. Brown Sr., Utah, in behalf of the Utah State Medical Association calling for membership in the county medical society of all hospital staff members is being administered now by the Council on Medical Education and Hospitals, pursuant to a resolution introduced and approved by this House of Delegates at the Cleveland session in 1934. It is interesting to learn that hospitals generally have cooperated with the spirit of this resolution.

RESOLUTIONS ON CLARIFYING POLICY OF THE AMERICAN MEDICAL ASSOCIATION ON QUESTION OF GROUP HOSPITALIZATION

Your committee believes that, for the purposes contemplated in the resolutions introduced by Dr. C. W. Stone, Ohio, as resolutions adopted by the house of delegates of the Ohio State Medical Association regarding problems from group hospitalization contracts, it is advisable to define hospital facilities rather than to attempt a comprehensive definition of medical practice.

It is recommended therefore that the contract benefit provided by group hospitalization insurance should be limited to the room, bed, board and nursing facilities ordinarily provided by hospitals, routine drugs, and the routine services of interns only when acting under the direction of the attending physician.

Except as stated above, the contract should not include the services of physicians either general or special. The term physician as used here shall be understood to include all licensed practitioners holding the degree of doctor of medicine and all others who assume on their own account to interpret laboratory findings in terms of disease and diagnosis or to administer or direct treatment.

RESOLUTION REQUESTING THE NORTH CENTRAL ASSOCIATION OF COLLEGES TO AMEND ITS MANUAL

Your committee has considered the resolution offered by Dr. T. R. K. Gruber, Michigan, in behalf of the Michigan State Medical Society, calling attention to certain health service requirements, set forth in the manual of accrediting procedure of the North Central Association of Colleges and Secondary Schools and to which exception is taken.

Your committee is in accord with the idea contained in this resolution and endorses the first paragraph of the summary published on page 95 of the Handbook as it applies to this resolution.

Your committee would urge that the North Central Association of Colleges and Secondary Schools modify its manual of accrediting procedures to permit each member institution to adopt its own health service in conjunction with its own county medical society and to comply with the principles enunciated in paragraph 1 of the summary published on page 95 of the Handbook.

Respectfully submitted.

F. S. CROCKETT, Chairman.
GEORGE BLUMER.
J. T. CHRISTISON.
C. A. DUKES.
W. E. VEST.

On motions, duly seconded and carried, the report of the reference committee was adopted section by section and as a whole, with the exception of that portion of the report referring to the Resolutions on Clarifying the Policy of the American Medical Association on the Question of Group Hospitalization, which was referred back to the reference committee.

Report of Reference Committee on Executive Session

Dr. Thomas A. McGoldrick, Chairman, presented the following report, which was adopted on motion of Dr. McGoldrick, seconded by Dr. Horace Reed, Oklahoma, and carried:

Your committee recommends that the time for hearing Hon. J. Hamilton Lewis, U. S. Senator from Illinois, be fixed for 11 a. m., Thursday, June 10.

Report of Reference Committee on Reports of Officers

With the Vice Speaker, Dr. H. H. Shoulders, Tennessee, presiding, Dr. Wingate M. Johnson, Chairman, presented the following report, which was adopted section by section and as a whole on motions, duly seconded and carried:

Your Reference Committee on Reports of Officers feels that all the addresses were of an unusually high order.

1. Address of the Speaker: The Speaker in his address paid a high tribute to the personnel of the House of Delegates. He also justly placed the responsibility for the policies of the American Medical Association on the members of the House, who are selected to represent the various members of the American Medical Association throughout the United States. He recognized the service of thirty-six veteran members of the House and also established a good precedent by introducing the seventeen new members.

2. Address of the President: The President's address was an excellent discussion of the present status of medicine in this period of social upheaval. He called attention to the fact that medicine was constantly making progress—is not static but dynamic.

Your committee commends his pertinent observation that society may be divided into four main groups, of which the wage earners have the greatest political power and are being exploited by astute politicians. He issues a timely warning against sabotage by "groups on the fringe of the profession."

Your committee recommends a careful study by all physicians of the eleven propositions laid down at the close of the address. It feels, however, that some of these propositions are problems for local communities and that the acceptance of government subsidies involves such basic principles that it should be considered most carefully. Your committee also feels that care should be taken to safeguard a great group of our profession who have contributed so much to its progress, namely, the radiologists and clinical pathologists.

3. Address of President-Elect: In his address the President-Elect called attention to the vast differences in the populations in our various states, in race, in distribution and interests—forming "insurmountable obstacles to providing a standardized practitioner or a single standardized type of medical practice." He recognizes that changes in medical practice are best accomplished through evolution rather than revolution. Your committee wishes to commend the two objectives of organized

medicine that he suggests: first, an extension of postgraduate instruction and, second, the education of the public along medical lines.

WINGATE M. JOHNSON, Chairman.
J. N. HUNSBERGER.
R. L. SENSENICH.
J. F. SMITH.
G. W. WELLS.

Reference Committee on Miscellaneous Business

Dr. J. D. Brook, Chairman, presented the following report, which was adopted on motion of Dr. Brook, seconded by Dr. Arthur C. Morgan, Pennsylvania, and carried:

Your committee has given diligent and thoughtful consideration to the Report of the Committee to Study Problems of Motor Vehicle Accidents appointed by the President at the Kansas City session and in the main it agrees and approves of the conclusions.

While we are all cognizant of the various conditions and situations which contribute to traffic accidents, particularly those mentioned in the report, your committee feels that the causes which are attributed to the physical and mental phase of the question are greatly in the minority and that, this being so, the responsibility of the medical profession does not go beyond making recommendations for curbing of driving by mental and physical defectives. Your committee therefore sincerely approves the paragraph advocating a standard drivers' license law and urges the legislative committees of the various state societies to extend their activities to this end.

And although your committee is not opposed to a symposium on the various phases of traffic accidents, it feels that we would be trespassing on a subject which is not broadly within our domain and therefore that, unless such a symposium could be conducted by experts who have daily contact with traffic accidents and who have given study to the subject, it would be of little value.

Your committee is further of the opinion that traffic morbidity and mortality can be greatly reduced by law enforcement. This contention is based on the fact that most accidents are caused by the smart, in-and-out, take-a-chance driver and the ignorant driver. Your committee therefore sincerely believes and recommends that, because of the general apathy toward the obedience of any law, the primary, individual and collective objective to reduce traffic accidents should be the rigid enforcement of the present law.

Respectfully submitted.

J. D. BROOK, Chairman.
H. L. BRYANS.
WALT P. CONAWAY.
C. S. SKAGGS.
C. W. WAGGONER.

Message from American Dental Association

Dr. Charles Gordon Heyd, President, read the following telegram received from Dr. Leroy M. S. Miner, president of the American Dental Association:

From the forty thousand members of the American Dental Association, greetings to you and to the members of the American Medical Association. Please accept best wishes for a meeting of marked distinction and deep significance for the future of medicine and the health of our people.

On motion, duly seconded by Dr. Arthur T. McCormack, Kentucky, and carried, the Secretary was instructed to send a telegram of formal acknowledgment of this greeting.

NEW BUSINESS

Proposed Amendment to By-Laws

Dr. George Gray Ward, Section on Obstetrics, Gynecology and Abdominal Surgery, in accordance with the wishes of that section, proposed the following amendment to the By-Laws, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Amend Chapter XIV, Section 1, subhead 3, of the By-Laws, which now reads "Obstetrics, Gynecology and Abdominal Surgery," to read "Obstetrics and Gynecology."

Resolution Approving Creation of Division of Water Pollution Control

Dr. A. T. McCormack, Kentucky, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Resolved, That the American Medical Association approve the passage of the bill (H. R. 2711) to create a division of water pollution control in the United States Public Health Service and for other purposes.

Resolutions on Time and Place of Annual Session

Dr. Walter E. Vest, West Virginia, presented the following resolutions, which were referred to the Board of Trustees:

WHEREAS, The annual sessions of the American Medical Association continue to attract an increasing attendance by the medical profession, so that many sessions now register in excess of 7,000 physicians; and

WHEREAS, the number of cities in the United States fully equipped with a suitable auditorium and a sufficient capacity of rooms in their hotels to accommodate those wishing to attend the session is limited; and

WHEREAS, It has become increasingly difficult to select a place for the annual session fully meeting the requirements and offering a date for the meeting most appropriate to the needs of the medical profession; therefore be it

Resolved, That the House of Delegates request the Board of Trustees between now and the next annual session to secure invitations for the annual sessions of the American Medical Association in 1939, 1940 and 1941 and that these invitations be submitted to the House of Delegates at the annual session of the Association in 1938, with the understanding that the House of Delegates will then select places of meeting for these three sessions and that in accordance with the Constitution and By-Laws the Board of Trustees may by unanimous vote change the place of session sixty days prior to any annual session or again submit the question to the House of Delegates should any contingency arise; and be it further

Resolved, That in 1939 the House of Delegates shall select the place of the annual session for 1942 and thereafter shall annually select the place of the annual session three years in advance of the date of meeting.

Resolution on Investigation of Claims of Osteopathy and Other Sectarian Methods of Practice

Dr. McLain Rogers, Oklahoma, submitted the following resolution, which was referred to the Board of Trustees:

WHEREAS, The claims of osteopathy and other sectarian methods of practice have never been investigated and reported on by any qualified agency in the United States; and

WHEREAS, The persistent exploitation of such claims, including the claim of osteopathy to be on a parity with the nonsectarian practice of medicine in every respect, reacts to the detriment of the public; and

WHEREAS, A demand is now being made by the representatives of osteopathy for the recognition of osteopathy by the United States government through the United States Employees Compensation Commission as equivalent in every respect to the nonsectarian practice of medicine so far as relates to the treatment of diseases and injuries among employees of the federal government; be it

Resolved, That the House of Delegates hereby respectfully requests the Board of Trustees to procure through the United States government an investigation by some unbiased qualified agency of the pretensions of osteopathy and of other allegedly healing cults.

Resolution on Average Daily Census in Hospitals

Dr. Henry A. Luce, Michigan, presented the following resolution, which was referred to the Reference Committee on Medical Education:

The House of Delegates of the Michigan State Medical Society at its 1936 meeting introduced and approved the following resolution: "Whereas, the Council on Hospital Examination of the American Hospital Association requires an average of 75 patients per day in hospitals for approval for intern training, and whereas, when such requirements are met with three interns are allowed, and whereas, such requirements work an injustice on hospitals having between fifty and seventy-five patients, because below seventy-five patients no interns are allowed and above seventy-five three are allowed, therefore, be it resolved that the delegates from the Michigan State Medical Society to the American Medical Association introduce a suitable resolution to lower this standard for approval for intern training to fifty patients per day."

The following resolution is therefore presented:

WHEREAS, The House of Delegates of the American Medical Association realizes the advantages accruing from hospitals approved for internship training having an average daily census of seventy-five or more; and

WHEREAS, It is of the opinion that the well equipped small hospital has distinct advantages; therefore be it

Resolved, That the House of Delegates of the American Medical Association direct the Council on Medical Education and Hospitals to approve hospitals meeting the requirements of the American Medical Association, which have a daily census of fifty.

Dr. Luce explained to the House the reasons for the introduction of this resolution.

Resolution on Evils from Promiscuous Use of Barbituric Acid and Derivative Drugs

Dr. Henry A. Luce, Michigan, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The public is in danger of untoward evil and toxic effects from the promiscuous use of barbituric acid and derivative drugs; and

WHEREAS, The beneficent value of these drugs when used under proper therapeutic supervision is recognized; and

WHEREAS, The procurement thereof is of easy availability in all but a few states; and

WHEREAS, The evils of these drugs include habit formations, toxic cumulative action, their substitution for alcoholic beverages for drunken episodes, their use for successful as well as unsuccessful suicidal attempts, their improper use being a recognized causative factor in many motor accidents and their improper use being a recognized etiologic factor in some criminal assaults; and

WHEREAS, The laity is unaware of the dangers involved in their promiscuous, unguided use; therefore be it

Resolved, For the protection of the public, that the sale of these drugs be placed under proper governmental control and that the Bureau of Health and Public Instruction be directed to proceed immediately with measures to accomplish this.

Resolution on Campaign Against Syphilis

Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, presented the following resolution, which was referred to the Board of Trustees:

WHEREAS, The record of the United States as regards infection with syphilis appears to be higher than that of many other civilized countries; and

WHEREAS, The United States Public Health Service has initiated a widespread campaign against the prevalence of this condition; and

WHEREAS, The early diagnosis, prevention and adequate treatment of syphilis rest on the physicians of this country; be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees to cooperate with the United States Public Health Service in connection with these efforts and do its utmost to carry to physicians the latest available information on these subjects.

Message of Sympathy

Dr. Holman Taylor, Texas, announced that Dr. S. E. Thompson, Kerrville, Texas, was prevented from attendance at the session because of the serious illness of his wife.

On motion of Dr. Taylor, seconded by Dr. Arthur T. McCormack, Kentucky, and carried, the Secretary was directed to send to Dr. Thompson a telegram of sympathy.

Resolution on Contraception from American Neurological Association

Dr. Olin West, Secretary, read the following resolution from the American Neurological Association, which was referred to the Reference Committee on Executive Session:

The committee on contraception of the American Neurological Association, recognizing the important advance that has been made in the matter of the physician's use of contraceptives by the decision of the United States Circuit Court of Appeals for the Second Circuit, Nov. 30, 1936, desires to present the following resolution:

WHEREAS, Because the aforesaid decision of the United States Circuit Court of Appeals has handed down to the medical profession a bill of rights in the field of contraceptive medicine, and because the decision marks the termination of a struggle begun in 1873 to make clear that the federal obscenity laws do not apply to the legitimate activities of the physician, and that he may now prescribe a contraceptive in the interest of life and health; be it

Resolved, That the American Neurological Association urge the American Medical Association again to consider seriously the inroads that are being made on the prestige of organized medicine by the rapid advance of popular thought in the matter of social medical science as evinced by the success of lay organizations in carrying out their program for greater medical freedom in the matter of contraception. It has come to the pass at which the road for medical advance is blazed by laymen assisted by the law. Unless organized medicine is directed by far seeing and free thinking leaders untrammelled by the aged and antiquated fetters of Sophism, it will most certainly come to pass that organized medicine will in the not distant future come entirely under the control of lay and legal administration assisted by their political allies. The American Medical Association is further urged to take up at once the matter of the proper teaching of contraception at the medical schools and the organization of medically supervised contraceptive clinics in hospitals. The time has passed for discussion and debate. The fact remains that the physician is now free to use contraceptives in his practice and should be educated in their use.

The House recessed for ten minutes.

Report of Committee on Legislative Activities

Dr. E. H. Cary, Chairman, presented the following report, which was referred to the Reference Committee on Legislation and Public Relations:

Mr. Speaker and Members of the House of Delegates:

In February your committee met in Chicago, at which time it reported to the Board of Trustees concerning information gained in conference with various agencies in Washington. The view presented at the time was that pending legislation was of such nature that little attention would be directed to legislation affecting medical practice. It was therefore generally agreed that members of the Committee on Legislative Activities would not engage in extraordinary activity in their individual duties but would be alert regarding any new developments. Later, in April, the situation was canvassed, and it was decided that it would be well for the committee to check again any legislation affecting medical practice before Congress and the various bureaus. The following is a brief summary of the contacts made on that occasion:

Veterans' Legislation: Many bills had been introduced, proposing to authorize erection of additional veterans' hospitals for general medical and surgical cases. These bills were still in committee. Your committee was informed by officials of the Veterans' Administration and others in authority that no program was under consideration for the erection of additional hospitals for the purpose named. The introduction of such bills, however, probably may be accepted as indicating a current tending toward the restoration to veterans of the right to hospitalization for any and all disabilities, whether of service origin or not. As yet no such movement has materialized.

There is, however, pending legislation intended to give veterans whose disabilities are due to their own misconduct, and who have heretofore been excluded, equal rights and privileges accorded other veterans. With enactment of such legislation, the veterans benefited would be added to the class now entitled to hospitalization, and it is hard to estimate the increase in number.

Social Security Legislation: Your committee was informed that the Social Security Board was making no special studies on health insurance. Consideration was being given to the feasibility of providing benefits for persons totally disabled, by disease or injury, before attaining the age at which they are entitled to old age pensions. Also they were studying a plan to provide relief for wage earners temporarily prevented by illness or injury from carrying on their usual occupations but who are not entitled to compensation under workmen's compensation acts or occupational disease acts. At present the relief contemplated to be directly provided by the government in both instances seems to be monetary benefits and not medical and hospital services.

Your committee calls the attention of the House of Delegates to the recent decision of the Supreme Court of the United States, which validated most of the Social Security Act. Quite evidently this opens an avenue for new legislation which could involve the profession of medicine. The question of whether the present or any other administration will take advantage of the Supreme Court's decision and develop new social legislation affecting medicine will depend, it is believed, in large measure on the attitude of medical men throughout the United States and the influence they exert on their respective Congressmen. So far, this administration has not publicly expressed a change from the attitude pronounced by the President in his address at the opening of the Medical Center in New Jersey.

Reorganization of Government Departments: In the February report to the Board of Trustees, your committee mentioned the committee on reorganization of government departments. In May, studies were still under way to determine the most efficient plan for reorganizing the executive branch of the federal government. The question of whether one or more new executive departments would be created was still undetermined. Seemingly it was more or less agreed that a place for the Public Health Service would be sought elsewhere than in the Treasury Department. Where it would be placed, and what other of the governmental medical services would be similarly placed, are matters remaining yet to be determined. Your committee has requested the committee on

reorganization to permit it to be heard before any definite decision is reached on this question.

Resettlement Administration Clients: The Resettlement Administration is now an agency of the Department of Agriculture, but the medical problems are in charge of a commissioned officer of the United States Public Health Service. Apparently the Resettlement Administration has no one plan for procuring medical service for its clients. Its general policy seems to be to find in each community the pathway of least resistance. Primarily, the administration is seeking cooperation from state medical associations in asking that they recommend to the component county societies that their respective members adjust medical fees to correspond to the resources of the relief clients. With such cooperation from the state medical association as a basis, it seems that representatives of the Resettlement Administration have been approaching the local medical organizations with a view to procuring the desired adjustment of medical fees. It has been said that the activities of the administration have sometimes gone beyond this and that efforts have been made to induce physicians to fix fees not on the basis of services rendered but at some given amount per annum regardless of the amount of work done. The dangers inherent in this type of contract are evident and it is hoped that objectionable permanence may not be encouraged in meeting an emergency need. Apparently it seems that the plans being formulated by the Resettlement Administration are designed to place the responsibility of medical service for Resettlement Administration clients on the medical profession.

Medical Use of Narcotics: At the Bureau of Narcotics, evidence was submitted that certain physicians played a part in facilitating the development and continuation of narcotic addiction. The apparent apathy of the medical profession in respect to the abuse by physicians of their authority to prescribe and dispense narcotic drugs for professional use was pointed out.

Incidentally, the statement has been made that a similar situation obtains regarding the prescribing of alcoholic beverages. The medical profession does not wish such conditions to exist.

Certainly it can be said that these abuses seem to be limited to very few men in the different states. On other occasions your committee has called your attention to the fact that the licensing authorities in the various states should be more diligent in revoking licenses of practitioners who abuse such privileges. In the instances in which the boards of licensure have no such authority and the wrongdoer has to be tried in a circuit court, seemingly it would be possible to have the law amended. Your committee believes that the great mass of medical men would support such activity on the part of the boards. There is no reason why one or two rotten apples should be permitted, even though we all agree there is no contaminating influence on ethical medical men.

The Secretary of the Treasury introduced a bill proposing to impose certain restrictions on the production, manufacture and use of cannabis and its preparations and derivatives. These are similar to the regulations of the Harrison Narcotic Act on opium and coca leaves and their derivatives and compounds. The duplication of registration, additional taxation and record keeping required by this proposed legislation seems to be without justification. The Harrison Narcotic Act may be easily amended to include cannabis and its preparations and derivatives. There is positively no evidence to indicate the abuse of cannabis as a medicinal agent or to show that its medicinal use is leading to the development of cannabis addiction. Cannabis at the present time is slightly used for medicinal purposes, but it would seem worth while to maintain its status as a medicinal agent for such purposes as it now has. There is a possibility that a restudy of the drug by modern means may show other advantages to be derived from its medicinal use.

Your committee also recognizes that in the border states the extensive use of the marihuana weed by a certain type of people would be hard to control.

Food and Drug Legislation: Since the Seventy-Fifth Congress convened last January, seven bills have been proposed for regulating interstate and foreign commerce in foods, drugs, diagnostic and therapeutic devices and cosmetics. One of these,

commonly referred to as the Copeland bill, was reported by the Committee on Commerce, without a hearing having been given, and promptly passed by the Senate. It is now pending, along with the various bills introduced in the House of Representatives, before the Committee on Interstate and Foreign Commerce of the House. These bills do not seem to provide adequate standards for drugs and for diagnostic and therapeutic devices, or adequate penalties for false or misleading advertising.

The definite weakness of these bills was pointed out. As a committee we have exerted every possible influence to see that a law will be so drawn that it shall be an improvement, rather than a backward step, in such legislation.

Helium for Experimental Use: At the 1936 session in Kansas City, the House of Delegates proposed legislation that would make helium available for medicinal research and use. The federal government has practically a monopoly on this gas. There is only one other source from which it may be obtained. The price charged by the private producer is so high that it almost prohibits further experimentation with the gas or its use medicinally. The proposed legislation contemplates the sale by the government of such surplus helium as may not be needed for military or other governmental purposes. Bills were introduced in the Senate and House of Representatives authorizing the sale of government-produced helium at cost. The Senate bill was favorably reported by the Committee on Military Affairs and is now on the Senate calendar. The House bill was given a hearing, but the committee has not yet made a report.

United States Employees' Compensation Act and Osteopaths: A bill has been introduced in the Senate and in the House proposing to authorize the treatment of injured or sick employees of the federal government under the United States Employees' Compensation Act by osteopaths on the same basis as that on which they may now be treated by doctors of medicine.

The law heretofore has called only for medical treatment. These bills proposed to sanction osteopathic treatment. In both houses the bills are in committee.

Rural Medical Service: The Committee on Legislative Activities last year brought to this House the substance of a conference with representatives of the American Farm Bureau Federation. It now submits the following resolution of the American Farm Bureau directed to the Legislative Committee of the American Medical Association:

Whereas, the health of the people is of paramount importance to the well being of society, individually and collectively; and

Whereas, under the existing order the medical needs of the great middle class of society and particularly of rural people are needlessly going unmet or provided for only in part; and

Whereas, as a result of the condition mentioned above, great unrest and dissatisfaction exists, particularly among rural people; and

Whereas, numerous proposals are being offered, and will be offered, promising to correct the situation described above; and

Whereas, many of these proposals are contradictory, evidencing the need for further research or the dissemination of authentic information and sound advice on the subject; and

Whereas, we welcome the cooperation of any group, and particularly that of the American Medical Association, in our endeavor to develop and to put into practice a sound, practical, fair health program;

Therefore be it resolved, that the medical committee of the American Farm Bureau Federation respectfully requests the Legislative Committee of the American Medical Association:

- (A) We earnestly request that the American Medical Association make a careful study of plans in operation by organized groups to reduce costs of medical care.
- (B) We ask that the members of county medical societies express their willingness to confer with groups of organized farm people in an attempt to work out local problems in a manner mutually acceptable.
- (C) That the county medical societies take into account, in fixing scale of charges, the prices received in the community for farm produce.

(D) That the American Medical Association give some earnest thought to the change of the out-dated method of charge for a bedside call. In most instances, these charges were determined when roads were bad and horses used for transportation.

(E) That the American Medical Association take some action on the subject of fee splitting. This practice often renders cost of consultation by specialists prohibitive.

We further ask that the American Medical Association assist the American Farm Bureau Federation in evolving some definite workable plans that will help our farm people to work out this vexing problem.

Respectfully submitted.

By: AMERICAN FARM BUREAU FEDERATION
Committee on Medical Care.

BEN KILGORE, Chairman, Executive
Secretary—Kentucky Farm Bureau
Federation.

HERBERT P. KING, President, New York
State Farm Bureau Federation.

MABEL D. AHART, Chairman, Farm
Home Dep't, California Farm Bureau
Federation, Western Region Board
Member, Associated Women.

FRANK W. WHITE, President, Minne-
sota Farm Bureau Federation.

MRS. CHARLES W. SEWELL, Adminis-
trative Director.

Your committee considers this an important communication as explaining the attitude of one of the most influential farm organizations in the United States. It believes that the members of this House should go on record as recommending to county medical societies their close cooperation with local farm bureau organizations for the purpose of adjusting costs of medical service in a manner satisfactory to physicians and the rural communities which they serve.

Respectfully submitted.

E. H. CARY, Chairman.

J. H. J. UPHAM.

C. B. WRIGHT.

F. S. CROCKETT.

R. L. SENSENICH.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Floyd S. Winslow, Chairman, presented the following report, which was adopted on motion of Dr. Winslow, seconded by Dr. George W. Kosmak, New York, and carried:

Your reference committee feels that this Association should be deeply grateful to the Committee on Medicolegal Blood Grouping Tests for its thorough and comprehensive review on this important subject.

Your reference committee particularly desires to emphasize the recommendation in the report of the committee that the international nomenclature for blood grouping as recommended by the Health Committee of the League of Nations be adopted as a standard by the medical profession in general.

Your reference committee agrees with the recommendations of the committee as follows:

"That, where necessary, laws should be passed which would authorize courts to order blood grouping tests in cases of disputed paternity and to receive the results thereof in evidence. Such laws could be modeled after those which have been passed in New York State and Wisconsin and the laws now pending before the legislatures in California and New Jersey. It is also recommended that the question of the qualification of medical experts should be reviewed."

Respectfully submitted.

FLOYD S. WINSLOW, Chairman.

ARTHUR C. MORGAN.

C. L. CUMMER.

J. F. SILER.

McLAIN ROGERS.

The Speaker announced that permission to attend the Executive Session on Tuesday afternoon, June 8, would be granted to officers of constituent medical associations and to alternate delegates of the American Medical Association who were not sitting as delegates, as well as to regularly seated delegates.

The House recessed at 12:20 p. m. to reconvene at 2 p. m.

Executive Session—Tuesday Afternoon, June 8

The House of Delegates was called to order by the Speaker Dr. N. B. Van Etten.

The Sergeants-at-Arms polled the House, after which the House went into Executive Session at 2 p. m.

Report of Reference Committee on Hygiene and Public Health

Dr. J. Q. Graves, Chairman, presented the following report, which was adopted on motion of Dr. Graves, seconded by Dr. W. H. Seemann, Louisiana, and carried after discussion:

Your committee has carefully considered the resolutions introduced by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, and with the approval and consent of Dr. Shurly desires to submit the following substitute resolutions:

WHEREAS, The family physician has labored for these many years without full recognition of his valuable services; and

WHEREAS, The various school systems of the United States depend on the family doctor for the prevention and diagnosis of disease and the protection of the public; therefore be it

Resolved, That the school boards and authorities in charge of the school systems all over our country be respectively requested to enter and file on the index card of every school child the name and address of the chosen family doctor; and be it further

Resolved, That the designated family doctor, together with the parents or guardians of the child, be informed by the proper school authorities of any accident or illness that may befall the child in the schools of this country; and be it further

Resolved, That it be recommended that all records of health examinations accompany the scholastic record of the child as he passes from grade to grade; and be it further

Resolved, That the provisions of these resolutions be brought to the attention of the secretary of each state medical association and that he, in turn, inform the secretary of each county medical society.

J. Q. GRAVES, Chairman.
L. B. BATES.
W. F. DRAPER.
MEREDITH MALLORY.
G. HENRY MUNDY.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. J. N. Baker, Chairman, presented the following report: Report of Committee to Propose Amendments to By-Laws Providing for Fitting Recognition to Fellows Rendering Distinguished Service in Science and Art of Medicine, which was submitted by the chairman of the committee, Dr. H. H. Shoulders, Tennessee: It was the unanimous opinion of the members of the reference committee that the sentiments expressed in this report and the purposes which it sought to accomplish were entirely commendable. Discussion within the committee, which was quite lengthy, largely revolved around suitable methods of procedure seeking to accomplish the end desired. Two amendments to the By-Laws were submitted with the report. These amendments, after careful consideration both by the members of this committee and by the proponents of the amendments, were altered in certain particulars with the end in view of better accomplishing the purposes set forth in the report. Your reference committee submits for the consideration of this House the following amendments:

Resolved by the House of Delegates of the American Medical Association that the By-Laws of the Association be amended by the addition of a new chapter, Chapter XI, to follow Chapter X, to read as follows:

CHAPTER XI.—COMMITTEE ON DISTINGUISHED SERVICE AWARDS

SECTION 1. There is hereby created a special committee to be known as the "Committee on Distinguished Service Awards of the American Medical Association."

This committee shall consist of five members, who shall serve for a period of three years, except the first committee, two of which shall be appointed for three years, two for two years and one for one year.

Nomination for the award may be made by any Fellow of the Association, provided it is made in a manner prescribed by the committee and not less than two months in advance of the next regular annual session of the Association.

SEC. 2. DUTIES AND POWERS OF THE COMMITTEE ON AWARDS. The Committee on Awards shall make its own rules of procedure, not in conflict with those By-Laws, with respect to the performance of its duties, subject to the approval of the Board of Trustees.

It shall consider the eligibility of nominees for the Distinguished Service Award of the American Medical Association on the basis of meritorious services in the science and art of medicine and shall submit its findings and recommendations to the Board of Trustees annually within a time limit fixed by the Board of Trustees.

In the event that more than five nominations are received, the committee shall elect therefrom a list of not more than five to be submitted to the Board of Trustees, together with a brief statement of its findings with reference to each.

The present Chapters XI, XII, XIII, XIV, XV, XVI, XVII, XVIII and XIX shall become Chapters XII, XIII, XIV, XV, XVI, XVII, XVIII, XIX and XX, respectively.

Resolved, By the House of Delegates of the American Medical Association, that Chapter VI of the By-Laws be amended by the addition of a new section after section 4, as follows:

SEC. 5. TO ESTABLISH A DISTINGUISHED SERVICE AWARD OF THE AMERICAN MEDICAL ASSOCIATION. The Board of Trustees shall create and establish an award to be known as the Distinguished Service Award of the American Medical Association, which shall consist of a medal and a citation.

One Fellow of the Association shall be eligible to receive the award each year and shall be selected in a manner prescribed in these By-Laws.

The Board of Trustees shall consider the merits of nominees for the award recommended by the Committee on Distinguished Service Awards and shall select from the list not more than three Fellows to be balloted on by the House of Delegates. The Board of Trustees shall submit the list of nominees so selected to the House of Delegates for consideration, together with a brief statement of the findings of the Committee on Awards with respect to each nominee.

The House of Delegates shall select the recipient of the award from the list of nominees submitted by the Board of Trustees. The selection shall be by ballot, in the same manner as officers are elected. The vote shall be taken immediately after the nominees are placed before the House by the Board of Trustees.

The Board of Trustees is charged with the duty of having a suitable medal and citation prepared each year and is further charged with the duty of fixing the time and method of presentation.

Your Reference Committee on Amendments to the Constitution and By-Laws of the Association recommends that approval be given to the following amendment, submitted by Dr. George Edward Follansbee, Chairman, Judicial Council:

Amend Chapter IX, Section 1, of the By-Laws by adding to the second paragraph the following sentence: "The period of time within which appeal to the Judicial Council may be taken shall be limited to the six months following the date of decision by the constituted authority of a constituent association."

The following proposed amendments to the Principles of Medical Ethics were submitted by Dr. George Edward Follansbee, Chairman of the Judicial Council: Amend Section 2 of Article VI so that only the first paragraph shall be included in that section under the heading "Conditions of Medical Practice," and that the remaining three paragraphs of that section shall be included under a section 3 with the heading "Contract Practice."

Amend the first paragraph of the new Section 3 to read as follows:

"SEC. 3. By the term 'contract practice' as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization or individual to furnish partial or full medical services to a group or class of individuals on the basis of a fee schedule, or for a salary or a fixed rate per capita."

In accordance with the above proposed amendments, the present Section 3, Article VI, under the heading "Commissions," becomes Section 4, and the present Section 4, under the heading "Direct Profit to Lay Groups" becomes Section 5.

Your reference committee recommends that approval of the House be given to this proposed amendment with the addition

of the words "political subdivision" after the word "organization" in the above section. The section will then read as follows:

"SEC. 3. By the term 'contract practice' as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization, political subdivision or individual, to furnish partial or full medical services to a group or class of individuals on the basis of a fee schedule, or for a salary or a fixed rate per capita."

Your reference committee recommends that approval be given to the proposed amendments to the By-Laws dealing with the President and the President-Elect of the Association, submitted by Dr. George Edward Follansbee, Chairman, Judicial Council, as follows:

Amend the By-Laws, Chapter IV, Section 1, last sentence to read "No member of the House of Delegates nor general officer of the Association shall be eligible for election to the office of President-Elect or Vice President."

Amend the By-Laws, Chapter IV, Section 8, to read: "Installation as President—The President-Elect shall be installed as and assume the duties of President at the opening general meeting of the Scientific Assembly of the annual session following that at which he was elected."

At the 1936 meeting of the House of Delegates held in Kansas City an amendment to the By-Laws was submitted by Dr. George Edward Follansbee, Chairman, Judicial Council, but the official record of the House does not show that this proposed amendment was properly acted on at that time. Your reference committee, therefore, again submits this amendment and recommends that proper official action be taken on it at this time:

Amend Chapter V, Section 1, fourth sentence, to read: "With the approval of the Board of Trustees he is authorized to appoint committees, (a) requested by the councils, and (b) for emergencies and purposes not otherwise provided for."

Amend Chapter IX, Section 1, the second power invested in the Judicial Council, to read "(2) all controversies arising under this Constitution and By-Laws and under the Principles of Medical Ethics, to which the American Medical Association is a party."

Add to Chapter IX, Section 1, the paragraph "The Judicial Council shall have authority in its discretion from time to time to request the President to appoint investigating juries to which it may refer complaints or evidence of unethical conduct which in its judgment is of greater than local concern. Such investigating juries, if probable cause for action be shown, shall report with formal charges to the President, who, under Chapter V, Section 1, of the By-Laws, shall appoint a Prosecutor, who, in the name and on behalf of the American Medical Association, shall prosecute the charges against the accused before the Judicial Council. The Council shall have the power to acquit, admonish, suspend or expel the accused."

Your reference committee recommends the adoption of the following amendment:

Amend Chapter XIV, Section 1, subhead 3, which now reads "Obstetrics, Gynecology and Abdominal Surgery" to read "Obstetrics and Gynecology."

Respectfully submitted,

J. N. BAKER, Chairman.
C. H. GOODRICH.
G. P. JOHNSTON.
V. E. SIMPSON.
T. F. THORNTON.

Motions were duly made, seconded and carried, that each section of the report and the report as a whole be adopted.

On motions duly made, seconded and carried, the amendments recommended by the reference committee were made to the By-Laws.

Report of Reference Committee on Executive Session

Dr. Thomas A. McGoldrick, New York, presented the following report:

1. Resolutions on the Development of a National Health Program, presented by Dr. Samuel J. Kopetzky, New York: Your reference committee believes that this subject presented here is too important, too vast and too widespread in its application to be justly and adequately considered in a few hours or

even a few days by any reference committee. It recommends that the resolution be referred to the Board of Trustees of the American Medical Association for consideration and action at the earliest possible time.

2. Report of Committee to Study Contraceptive Practices and Related Problems: Your reference committee had before it the following report:

Your committee was appointed by the Board of Trustees pursuant to a resolution adopted by the House of Delegates June 11, 1935, as follows:

WHEREAS, Under the stimulus of large nonmedical groups, the general use of contraceptives is being advocated and encouraged despite the existing law, not only by the above mentioned groups but by commercial interests as well; and

WHEREAS, The ultimate effect of these measures on the health and general welfare of the population of the United States is unknown if not questionable and should accurately and extensively be studied by the medical profession, in whose care the health of the people rests; and

WHEREAS, The laws, both federal and local, governing the physicians in their advice to individual patients, where such advice is given as a therapeutic measure, seem to be complicated, not well understood, and generally unsatisfactory, and their interpretation difficult; therefore be it

Resolved, That a special committee be appointed after due consideration by the Board of Trustees to study these related problems and to present at least a preliminary report to the House of Delegates of the American Medical Association at the 1936 annual session; and be it further

Resolved, That the trustees be requested to appropriate the funds necessary in order to carry out the purposes of these resolutions.—*Proceedings, House of Delegates, 1935, p. 45.*

The committee submitted its first report at the Kansas City session of the House of Delegates in 1936. That report, modified as suggested by the Reference Committee on Executive Session, was adopted by the House on May 12. Pursuant to the report as thus adopted, the committee was continued by the Board of Trustees "to continue a study of birth control and to report further to the House of Delegates." This report is submitted in compliance with that mandate.

Since the first report of the committee was submitted, the committee has received communications from various organizations interested in the subject, which will be presented to the House of Delegates.

The present report of your committee is limited to a consideration of the prevention of conception only as it refers to the relation of physician and patient.

Information concerning contraception is admittedly available to persons in favorable economic circumstances. There appears to be no law to prevent physicians who work in dispensaries from furnishing patients there with any information that may lawfully be furnished to patients in any other economic group. In all cases, the legal justification is the medical need of the patient.

All dispensaries, clinics and similar establishments where information and advice concerning the prevention of conception are given to the public should in the opinion of your committee be under legal licensure and supervision and under medical control.

Medical conditions which make conception inadvisable or contraindicate it were listed in the first report of your committee. Nothing has come to the attention of the committee since that report was submitted requiring any significant modification of that list.

In view of the frequent occurrence of medical indications for the prevention of conception, and in view of the medical complications that arise from ill advised contraceptive practices resorted to by women on their own initiative and without medical advice, which call for medical care, medical students should, in the opinion of your committee, be instructed fully concerning fertility and sterility and taught the clinical considerations and therapeutic application of contraceptive methods.

It is recognized that voluntary family limitation is dependent largely on the judgment and wishes of individual parents. The intelligent, voluntary spacing of pregnancies may be desirable for the health and general well being of mothers and children. This raises the question of how many pregnancies are biologically desirable and physically safe, and of the best practical means for determining the proper interval between them. No arbitrary interval can be stated. A variety of factors must be considered, including the patient's general health, the character of the previous pregnancies and labors and of recovery from

their effects, and the incidence of intercurrent illness. Your committee reiterates the opinion, expressed in its first report, that each case must be determined by the individual judgments of parents and physician, based on the conditions present.

In its first report your committee stated that it had been unable to find evidence that existing laws, federal or state, had interfered with any medical advice which a physician felt called on to furnish his patients. This view has been supported by the recent decision of the United States Circuit Court of Appeals, Second Circuit, Dec. 7, 1936, in *U. S. v. One Package*, in which it was held that a statute the words of which forbade absolutely the importation of articles for the prevention of conception was not designed to prevent the importation of things which might intelligently be employed by conscientious and competent physicians to save life or to promote the well being of patients. Although the statutes in force in the several states that forbid the dissemination of information concerning methods for the prevention of conception do not in express terms exempt physicians from their operation, it seems fair nevertheless to assume that the state courts, if called on to construe them, will adopt lines of reasoning similar to those followed in the case cited and in other cases decided by United States courts, leaving physicians free to give information concerning contraception when required to meet the medical needs of patients.

In view of the admitted medical necessity for avoiding conception in certain cases and of the general use of contraceptive preparations and devices, your committee finds no reason why the American Medical Association should not investigate such substances and devices. Such investigations for medical purposes seem to constitute a logical part of the activities of the Association in the field of therapeutic research.

RECOMMENDATIONS

Your committee respectfully submits the following recommendations:

1. That the American Medical Association take such action as may be necessary to make clear to physicians their legal rights in relation to the use of contraceptives.

2. That the American Medical Association undertake the investigation of materials, devices and methods recommended or employed for the prevention of conception, with a view to determining physiologic, chemical and biologic properties and effects, and that the results of such investigations be published for the information of the medical profession.

3. That the Council on Medical Education and Hospitals of the American Medical Association be requested to promote thorough instruction in our medical schools with respect to the various factors pertaining to fertility and sterility, due attention being paid to their positive as well as to their negative aspects.

CARL HENRY DAVIS, *Chairman*.
GEORGE W. KOSMAK.
W. A. COVENTRY.
RICHARD J. O'SHEA.
JOHN ROCK.
WILLARD RICHARDSON COOKE.

JAMES R. BLOSS } *ex officio*
W. C. WOODWARD }

The committee appointed in 1935 to study the subject of birth control and related problems made its report in 1936 at the annual session of the American Medical Association. The committee was continued at the 1936 session for further study of the related problems. Its present report is on contraceptive practices. With slight modifications your reference committee approves the recommendations now made and recommends that there be added to the first recommendation, "That the American Medical Association take such action as may be necessary to make clear to physicians their legal rights in relation to the use of contraceptives," the words "emphasizing the fact that all considerations in this report on the subject of the prevention of conception have their application only in conditions arising in the relation of physician and patient," and that this recommendation so modified be referred to the Bureau of Legal Medicine and Legislation.

Your reference committee recommends that the second recommendation, "That the American Medical Association undertake

the investigation of materials, devices and methods recommended or employed for the prevention of conception with a view to determining their physiologic, chemical and biologic properties and effects, and that the result of such investigation be published for the information of the medical profession," be referred to the Council on Pharmacy and Chemistry and also to the Council on Physical Therapy.

Your reference committee recommends that the third recommendation, "That the Council on Medical Education and Hospitals of the American Medical Association be requested to promote thorough instruction in our medical schools with respect to the various factors pertaining to fertility and sterility, due attention being paid to their positive as well as to their negative aspects," be referred to the Council on Medical Education and Hospitals.

Your reference committee further recommends that information and advice concerning the prevention of conception given in dispensaries, clinics and similar establishments should be given only in such dispensaries, clinics and similar establishments legally licensed to treat the sick and under medical control.

In accordance with the usual procedure of the American Medical Association all letters, communications and resolutions of individuals and societies bearing on the subject of birth control and its related problems which have been sent to the American Medical Association were referred to and were fully considered by the committee on those subjects before and in the making of its report. This includes the resolution offered this day from the American Neurological Association.

Your reference committee recommends that the Committee to Study Contraceptive Practices and Related Problems be not discharged at the present time but that its existence be continued for the purpose of supplying any assistance which it may be called on to render.

Respectfully submitted.

THOMAS A. MCGOLDRICK, *Chairman*.
J. H. CANNON.
E. H. CARY.
E. F. CODY.
JOHN H. FITZGIBBON.

The first section of the report of the reference committee, dealing with resolutions submitted by Dr. Samuel J. Kopetzky, New York, was referred back to the reference committee, on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. H. B. Everett, Tennessee, and carried.

It was moved by Dr. Francis F. Borzell, Pennsylvania, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried after discussion, that a copy of the resolutions presented by Dr. Kopetzky be placed in the hands of each of the delegates.

The second section of the report of the reference committee, dealing with contraception, was adopted section by section and as a whole, on motions duly made, seconded and carried.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. A. T. McCormack, Kentucky, and carried, the House rose from Executive Session at 3:40 p. m. and reconvened in regular session.

Report of Reference Committee on Legislation and Public Relations

Dr. T. M. Townsend, chairman, presented the following report:

To the Members of the House of Delegates of the American Medical Association: Your Reference Committee on Legislation and Public Relations has the honor to submit the following report:

With reference to the Resolution on Administration of Anesthesia, introduced by Dr. Walter A. Lane, Massachusetts, your reference committee believes that in principle the administration of anesthetics, the interpretation of roentgenograms, the interpretation of laboratory findings and the application of physical therapy measures constitute the practice of medicine and should be confined to those who are licensed practitioners of medicine. However, your reference committee also believes that in practice it is at present inexpedient to urge the enforcement of the provisions of this resolution.

The Resolution on Establishment of a Department of Public Relations, presented by Dr. L. J. Hirschman in behalf of the Michigan State Medical Society, has the hearty endorsement of your reference committee, which recommends its adoption in letter and in spirit and that the Board of Trustees indicate the technic of its accomplishment.

With reference to the Resolution on Opposition to Copeland Food and Drug Bill, introduced by Dr. Walt P. Conaway in behalf of the Medical Society of New Jersey, your reference committee recommends that the American Medical Association pledge its support to any movement looking toward the promotion of sound and effective legislation, federal and state, for the protection of the public against fraud and deception in the manufacture, distribution and sale of foods, drugs, prophylactic, diagnostic and therapeutic devices, and cosmetics.

The Resolution Approving Creation of Division of Water Pollution Control, introduced by Dr. A. T. McCormack, Kentucky, has the unanimous support of your committee, which recommends its adoption.

The report of the Committee on Legislative Activities has been carefully studied by your reference committee. That report relates the activities of the committee on many legislative matters affecting the public and the profession. It calls attention to the validation of the Social Security Act and how this might open avenues for new social legislation which might affect medicine; to the inadequacies in the food and drug legislation, and to the apparent unfairness of the Resettlement Administration authorities in placing the responsibility of medical service to their clients on our profession at a fixed fee per annum regardless of the amount of work required or responsibility involved. It also considers the inequalities of the distribution of medical care to rural communities and recommends to county medical societies their close cooperation with all rural organizations for the purpose of adjusting the cost of medical service in a manner satisfactory to physicians and to the rural communities which they serve.

That portion of the report of the Board of Trustees concerning the Bureau of Legal Medicine and Legislation has received your reference committee's attention and consideration. The narration of the activities of the Bureau gives evidence of its close touch and intimate contact with all legislation pertaining to the relations between the public and the profession. Doubtless, its close scrutiny, careful analysis and constructive advice have affected this legislation to the benefit of all concerned.

That portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics goes into careful detailed consideration of the question of group hospitalization. Your reference committee commends the principles stated in that section of the report pertaining to group hospitalization and recommends the adoption of those principles as the policy of the American Medical Association, and it is urged that medical societies in those communities in which group hospital insurance is thought to be necessary be guided by these principles to the end that such schemes confine their contract benefits strictly to the facilities ordinarily provided by hospitals; viz., hospital room, bed, board, nursing, routine drugs. It is suggested that the Bureau of Medical Economics continue to collect factual and statistical data concerning group hospital insurance experience and make these facts available from time to time.

Although that section of the report of the Bureau of Medical Economics on rural medical service has already been considered in the report of the Committee on Legislative Activities, your reference committee urges serious consideration of that section of the report. It appears that because of a wide diversity of factors no uniform plan of distribution of medical services in rural communities can be adopted. It is recommended, however, that county medical societies, wherever the necessity exists, cooperate with local organizations in providing, supplementing, reorganizing or modifying good medical services to the rural population.

That portion of the report of the Board of Trustees devoted to the Bureau of Health and Public Instruction is a simple narrative of the work of that bureau during the past year. Your reference committee commends its industry and expresses the gratitude of the Association for its faithful work.

That section of the report of the Board of Trustees on Occupational Diseases and Industrial Medicine has received the careful consideration of your reference committee. Since

industrial health has become increasingly important, your reference committee believes that this Association should continue to act in such a way as will enable it to be of the greatest assistance in the prevention and control of industrial accidents and disease. Your reference committee recommends that to this end the American Medical Association establish a Council on Industrial Health which shall concern itself with matters pertaining to the control and prevention of occupational disease.

Respectfully submitted.

T. M. TOWNSEND, Chairman.
J. C. FLIPPIN.
H. T. LOW.
S. H. OSBORN.
J. G. TAYLOR.

On motions duly made, seconded and carried, the report of the reference committee was adopted section by section and as a whole, the Speaker ruling that the section recommending the establishment of a department of public relations, which involves the expenditure of money, will have to be referred to the Board of Trustees without further debate.

Report of Council on Scientific Assembly

Dr. Irvin Abell, Chairman, presented the following report, which was adopted on motion of Dr. Abell, seconded by Dr. George Gray Ward, Section on Obstetrics, Gynecology and Abdominal Surgery, and carried:

The Council on Scientific Assembly has considered the resolution introduced by the delegate from the Section on Obstetrics, Gynecology and Abdominal Surgery, relative to change in title of that section and, in view of the grounds mentioned therein and further that such change in title is requested by the section involved, recommends its adoption.

The Council further recommends that Chapter XIV, Section 1, subhead 3 of the By-Laws be amended to read "Obstetrics and Gynecology."

IRVIN ABELL, Chairman.
FRANK H. LAHEY.
JAMES E. PAULLIN.
A. A. WALKER.
J. C. FLIPPIN.

Report of Board of Trustees

Dr. Rock Sleyster, Chairman, presented the following report:

The Board of Trustees has considered the several resolutions referred to it by the House of Delegates this morning and recommends the approval of the following:

Resolutions on Time and Place of Annual Session introduced by Dr. Walter E. Vest, West Virginia.

Resolution on Campaign Against Syphilis introduced by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology.

Relative to the resolution introduced by Dr. McLain Rogers, Oklahoma, the Board of Trustees has had this matter under consideration and will continue to keep it under surveillance to see what can be done regarding it.

On motions, duly seconded and carried, the report of the Board of Trustees was adopted section by section and as a whole.

Request for Special Session of House

Dr. E. F. Cody, Massachusetts, as a member of the Reference Committee on Executive Session, moved that a special session of the House of Delegates be held Wednesday, June 9, at 2 p. m. The motion was seconded by Dr. James Q. Graves, Louisiana, and carried after discussion.

Executive Session

State Medical Defense Plans

Dr. Charles S. Skaggs, Illinois, requested the courtesy of the House to hear Dr. J. R. Ballinger, Chicago, with respect to the situation arising out of the ruling of a committee of the American Bar Association that a state association was practicing unauthorized law in the operation of its medical defense plans.

It was moved by Dr. Arthur T. McCormack, Kentucky, seconded by Dr. H. B. Everett, Tennessee, and carried, that the privileges of the floor be extended to Dr. Ballinger.

On motion of Dr. B. F. Bailey, Nebraska, seconded by Dr. Horace Reed, Oklahoma, and carried, the House went into executive session at 4:20 p. m. with Dr. N. B. Van Etten, Speaker, presiding.

Dr. J. R. Ballinger, Chicago, and Dr. W. C. Woodward, Director, Bureau of Legal Medicine and Legislation, addressed the House on the ruling of the Committee on Unauthorized Practice of Law and the Committee on Professional Ethics and Grievances of the American Bar Association.

The House recessed at 4:50 p. m.

Third Meeting—Special Executive Session, Wednesday Afternoon, June 9

The House convened in special executive session with the Speaker, Dr. N. B. Van Etten, presiding.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. J. N. Baker, Chairman, presented the following report:

The resolution to amend the Constitution dealing with the election of the President and President-Elect of the Association, introduced by Dr. George Edward Follansbee, Chairman, Judicial Council, has received consideration at the hands of your committee.

The purport of the amendment to the present Constitution is to make better provision for succession in office in case of death or of disability of the President-Elect. In giving consideration to this important matter, your reference committee feels that this body might take under advisement the possibility of providing by constitutional amendment a Vice President-Elect to be included in the general officers of the Association. Such provision is not made in the present Constitution, nor does the proposed amendment make such provision. Such provision would necessitate the amendment of Section 1 of Article VI of the Constitution by including a Vice President-Elect as one of the general officers of the Association, as well as making certain alterations in the phraseology of the proposed amendment.

Since this is an amendment to the Constitution, it will have to lie over for a period of one year before final action can be taken by this House.

Respectfully submitted.

J. N. BAKER, Chairman.
C. H. GOODRICH.
G. P. JOHNSTON.
V. E. SIMPSON.
T. F. THORNTON.

It was moved by Dr. Baker, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, that the report of the reference committee be adopted.

The Speaker announced that the proposed amendment would lie over for one year.

The Sergeants-at-Arms reported that the House had been polled.

Cooperative Medical Service Organizations

The Speaker announced that the subject of cooperative medical service organizations might well come before the House in executive session and asked Dr. E. H. Cary, Texas, to present the matter to the House.

Dr. W. C. Woodward, Director, Bureau of Legal Medicine and Legislation, at the request of Dr. Cary, made a statement to the House concerning cooperative medical service organizations.

Report of Reference Committee on Executive Session

Dr. Thomas A. McGoldrick, Chairman, presented the following report:

Your reference committee has carefully considered the Resolutions on the Development of a National Health Program, introduced by Dr. Samuel J. Kopetzky in behalf of the New York delegation, and has held hearings at which the details of the principles and proposals were freely discussed.

The Board of Trustees has already reported to this House of Delegates its considered opinion pertaining to the reorganization, in one consolidated department, of the activities of the federal government having to do with the promotion of health and the prevention of disease. Copies of this statement, as printed in THE JOURNAL and in the Handbook of the House of Delegates, were transmitted to the President of the United States and to others in official position in Washington, and the attention of constituent state medical associations was especially called to the action of the Board, as follows:

"Recognizing that committees of the Senate and of the House of Representatives of the United States government and a special committee appointed by the President are at this time concerning themselves with the reorganization of government activities with a view to greater efficiency and economy, and recognizing also that the President, in his opening address to Congress, indicated that he would shortly present to the Congress recommendations for such reorganization of government activities in the executive branches, and recognizing moreover the great desirability that all activities of the federal government having to do with the promotion of health and the prevention of disease might with advantage be consolidated in one department and under one head, the Board of Trustees of the American Medical Association would recommend that such health activities as now exist be so consolidated in a single department which would not, however, be subservient to any charitable, conservatory or other governmental interest. It has been repeatedly said that public health work is the first problem of the state. It is the opinion of the Board of Trustees that health activities of the government, except those concerned with the military establishments, should not be subservient to any other departmental interests. This reorganization and consolidation of medical departments need not, under present circumstances, involve any expansion or extension of governmental health activities but should serve actually to consolidate and thus eliminate such duplications as exist. It is also the view of the Board of Trustees that the supervision and direction of such medical or health department should be in the hands of a competently trained physician, experienced in executive administration."

Since the House of Delegates during this session has already approved this action of the Board of Trustees, your reference committee deems it unnecessary to submit for your consideration that portion of the resolutions which deals with this subject.

Your reference committee recognizes that certain principles stated in the resolutions presented by Dr. Kopetzky have been considered by the House of Delegates on previous occasions and are matters of record. These include, for example, the recognition of the primary importance of public health, the opposition to compulsory sickness insurance and the separation of the problem on economic need and the distribution of medical service.

The Board of Trustees has given careful consideration to the extension of medical service to the indigent, as indicated in the following statement, which was contained in the report of the Board of Trustees as printed in the Handbook and which was approved by this House during its session June 8, 1937:

"In the past, the medical profession has always been willing to give of its utmost for the care of those unable to pay. The available evidence indicates that today throughout the United States the indigent are being given a high quality of medical care and medical service. Nevertheless, the advances of medical science have created situations in which a group of the population neither wholly indigent nor competent financially find themselves under some circumstances unable to meet the costs of unusual medical procedures. The Board of Trustees of the American Medical Association points out the willingness of the medical profession to do its utmost today, as in the past, to provide adequate medical service for all those unable to pay either in whole or in part. Members of the medical profession, locally and in the various states, are ready and willing to consider with other agencies ways and means of meeting the problems of providing medical service and diagnostic laboratory facilities for all requiring such service and not able to meet the full cost thereof. These are problems for local and state consideration primarily rather than problems of federal responsibility. The willingness of the medical profession to adjust its services so as to provide adequate medical care for all the people does not constitute in any sense of the word an endorse-

ment of health insurance, either voluntary or compulsory, as a means of meeting the situation."

The American Medical Association is cognizant of the medical needs of the people of the United States and is genuinely interested in all plans for providing and distributing medical care. The records, reports, source material and experience of the Association are of great value. They are at the service of agencies contemplating the development and operation of plans for medical care. These factual data, source material and experience are readily available for use in promoting and protecting the health of the American people.

Your reference committee recommends that the bureaus, councils and committees of the Association continue their studies of the need for and the methods of distributing medical care, to the end that the American Medical Association shall continue to do everything possible to promote and to protect the health of the American people.

The American Medical Association reaffirms its willingness on receipt of direct request to cooperate with any governmental or other qualified agency and to make available the information, observations and results of investigation together with any facilities of the Association.

With respect to proposals for a National Department of Health, your reference committee refers to the report of the Board of Trustees in the Handbook, page 107, which has just been read.

Your reference committee believes this fully covers the subject.

Respectfully submitted.

T. A. MCGOLDRICK, Chairman.
E. F. CODY.
E. H. CARY.
J. H. FITZGIBBON.
J. H. CANNON.

On motions, duly seconded and carried, the report of the reference committee was adopted section by section and as a whole.

The House recessed at 2:55 p. m., to meet in Special Executive Session on Thursday, June 10, at 11 a. m.

Special Executive Session—Thursday Morning, June 10

The House of Delegates convened in Special Executive Session at 11:15 a. m. and was called to order by the Speaker, Dr. N. B. Van Etten.

Address of Past President William Allen Pusey

The Speaker announced that Hon. J. Hamilton Lewis, U. S. Senator from Illinois, was on his way to the meeting to address the House. In the meantime he called on Past President William Allen Pusey, Chicago, who addressed the House as follows:

It is quite an unexpected situation for me to be asked to fill in for Senator Lewis and to make a speech without warning. As far as I can judge from my experience, it would not be fair to most people for anybody to be asked to present a speech before he prepared it. I haven't anything to say. I am delighted to be here. I appreciate, of course, the high honor of being asked to come up here today. I am interested in the proceedings of the House of Delegates. As far as I can learn from sitting on the sidelines and talking to a few wise men, the House is wise as usual. I hope you are having a very comfortable and agreeable meeting, with altruism prevailing. No man could ask for more. All I can do is to hope that your wisdom will long continue.

Address of Hon. J. Hamilton Lewis

Dr. Holman Taylor, Texas, escorted Hon. J. Hamilton Lewis, U. S. Senator from Illinois, to the platform, and the Speaker presented Senator Lewis, who addressed the House, as follows:

I recall with great gratification when you did me the compliment, on the suggestion of our distinguished fellow citizen Dr. Fishbein and your organization, to let me have some words

with you in a previous meeting. Then I boldly took the liberty to chide my brother profession on the fact that they remained always doctors and declined in the political world to be citizens. I recall that I dared to point out the changing affairs coming in the world, and how I saw that the influence of the doctor in the family and on the citizens where he lived was going to be so necessary that, if he exerted it, much would be done to avoid what I saw was a coming complication and serious confusion. If he deferred on the delicacy which many of them have—indeed all of them—that being doctors they must keep hands off of political subjects, there would be much to regret. There would be so few laying on hands in an unselfish attitude to win respect for the physicians.

Today you have been kind enough to let me visit for some reasons that all of you have not had time to understand. That is why I so audaciously asked the privilege to speak again to you.

I thank you, dear Mr. Chairman, for your reference to me, particularly your kindly and generous flattery as to the kind of Senator you were good enough to speak of. But I want to confide to you something very confidentially among professional brethren—I wouldn't attach too much importance to that designation called "Senator." . . .

[Here Senator Lewis interspersed an anecdote about the Senate.]

Doctors, I have a few words that you will allow me, I am sure, to express. I wanted to have some words with you, not to advise you, but to ask your advice, that you may understand my position. Busy as you are in your own matters, I reveal to you that which has been greatly disturbing me.

I helped write, helped prepare, and naturally as a whip and the parliamentarian of the Senate helped pass, the law you refer to as the Social Security Law. I address myself to that feature which concerns the doctors. I have not been able to agree with the gentlemen of the committee and find myself very much at variance with nearly every one who seems to touch this subject.

In the first place, I want you to know that I have felt that our country is so far away from the necessity of directing matters of the application of medicine as coming from you gentlemen that when we did approach it we approached it as a political subject. We approached it on the basis of what might be called charity and relief. I fear we quite overlooked that there was a scientific situation that had to be considered in order that justice be done all those who would be affected by the result.

You gentlemen of the profession hesitated to touch this subject. Many who felt kindly, and who in your local organization have ever done so much to aid the miserable and relieve the depressed, still shrunk to the point almost of resentment against government assuming to sit in direction as to your method of the application of your science. There was within you that in which I assure you the law and the lawyer quite fully conjoin with you: a resentment against that thing called government assuming to dominate you, control and direct you in the matters where your discretion, guided by your sense of right and your learning, directed through your years of experience, should be the sole and whole influence.

You hesitated to accept the suggestion and you naturally felt that there was an attempt on the part of the government to take from you initiative and independence of two relations, one as doctor, the other in your contractual relation of doctor and patient. I beg to say to you that you have reached a point where the change in all government must attract your attention. If you feel, dear gentlemen, that settling about in the pursuit of your undertaking and preparing the course of this great profession which you undertake to guide there has entered something of innovation and invasion, I beseech you to pause and realize that there is nothing that is not now undergoing some form of encroachment by those who fancy they know a system better than that prevailing, or by those who, because of power politically, dominate with the control an office may give.

May I speak of myself? Where I am we have a band of men among whom is your servant. We are having serious war against what is known as a set of rules called Supreme Court of the United States Rules. They are a body of law in which the whole profession of the law and its method of

practice is being revised. A new system is being put upon the lawyer, beneficial let us feel in many respects, to redeem the law from being looked on as an instrument of either mystery or persecution, but which we as a profession hesitate to accept. We have been fighting and continuously opposing it, and from the very spiritual reason that you gentlemen in your profession have not been inclined, taking you generally, to adopt this invasion upon yourselves.

But, doctors, the question for you is not whether you like it or whether you don't; whether within yourselves you feel you are better for it individually or not. The question for you is What is to be done about it? I want you to recognize one of those who recall that all your past has been that of the doctor and its patient. The patient steps up now and says "I have a voice unto myself. I am the subject of this treatment, and I am either to be the beneficiary or the victim of your procedure." Yes, and then he is having those around him that teach "Well, what right has this man anyhow?"

"He is a man. He has a right as a man."

"Correct."

"And he has a right to learn these systems which he speaks of as medicine."

"Also correct."

"But what right has he to organize a society and say to his fellow 'You can't come into this society unless you conform to certain regulations we have made for you and then pass examination and in this be so complete that we will give you our certificate' and yet in the meantime turn to the state and say 'But you can't make a certificate for us or create a society or organization that prescribes limitations.'"

Then comes the other to rise up and say "Yes, but you doctors have been a busy lot dividing yourself between those who sincerely in your profession seek to alleviate distress and others who look upon your profession as an avenue and an agency of enriching yourself, and between these two haven't you overlooked the fact as to who you are? You forget that everybody around you has been regulated by the new order of government. That man James Hamilton Lewis and his colleagues, who are they? They have from time to time been compelled to submit first to their bar association, then to some regulation, then to the right of the judge to expel them from practice, and now under the new theory their higher court, called the Supreme Court, to give the privilege even to let them practice, and if to practice to reserve the right to reform them, supervise them and dismiss them. In addition to this there has been created for those lawyers the right of the judge to name any one of them to defend and represent any human being, and as their oath to their duty is similar to that which is your distinguished Grecian oath to your profession, he has no right to complain. And if he attempts to do so he will be dismissed from the privileges of collecting his money by the law."

They turn to you doctors and say "Do you recognize, Mr. Doctor, something else of yourself? What rights have you, sir? You have learned this that gratifies you and in your heart you would serve your fellow man. That is gratifying to all those who know you. But what right have you to charge money for it? Where do you get the privilege of exacting the right to make your fellow man pay you? You get it because you give a consideration of service and you have a right to have the exaction of a fair compensation. But you go further. The state authorized you as an officer of the state to proceed into the tribunals of the state called the courts to enforce payment." Do you know, you can't collect your money, you can't testify? You have served a man a year or two, and nature in the course of things takes him away. He has a large estate or small; we will speak of the large one. You know what is due you. Do you think you can get it? Under an ancient system of the law handed down long ago to prevent the living from putting words in the mouth of the dead and thus working a fraud, there is a provision of the law which we adopted that prohibits a man who brings suit against that which is dead from taking the witness stand; he cannot testify. What is the result on the doctor? The result is you can't get on the stand and testify how long you have served that man, the nature of his malady, and bring in your brethren to show that your services called for scientific application, and you are not allowed to speak of what would be the value of your service.

You must take your chances to try to get your money out of the administrator, the executor of the will, by whatever system can be devised by those of your brethren who know nothing about that which you could have testified had you been allowed to tell the truth about it.

I mention this only to show how little you have been regarded within the processes of the law as to your real rights in the collection of that which is due you.

In the meantime, how do you think you stand now? You are giving attention for a moment to some advice from one of your fellow citizens on a matter which he dares to assume you have not thought about and to which he presses you now for serious deliberation. Are you aware that in the last forty-five years there has been a gradual accumulation in matters of national health, immigration, etc., of a form of federal procedure touching your conduct on certain classes of people—sometimes we speak of them as foreigners and sometimes immigrants—under the narcotic administration? Are you aware that you have been admitted to the practice in the state in which you live, that under that practice you are conforming to some regulations? But I propound to you: What right have you to take up any of these matters federal? Where do you get your rights? I am a lawyer. I must be admitted to my state bar; I must be admitted to the county bar, but I must be admitted to the United States federal courts before I can rise in a federal court to seek in behalf of my client his rights under the federal law. Do you know what is going to happen to you? That is why I want a word with you seriously. You are going to have a certain set of individuals, thoughtless from my point of view, meaning nothing unkindly to them, who are shortly going to demand of you that there be a system of examination and application by the federal government on every doctor of America and to prove his right to be admitted to practice under the federal law in addition to that which he is now enjoying under his local acts. Then we will come about to the thing which I am utterly against and wholly abhor but which I tell you is on its way: the designation of a certain class of doctors named by the President or by some officers of the federal government, who then become a board who are to pass on their fellow doctors having the right to be admitted to be a practitioner under the federal law.

Naturally, something in you says "Lewis, you don't really mean that there is an attitude of mind of that kind in the land?" And I am compelled to say to you, my dear comrade, not only do I mean there is such a prospect, I mean to come here today and tell you it is on you and you have got to pause to consider it, and that is why I have come to ask your advice.

I helped to draw the provision that relates to the doctor. I have been one of those, as our dear friends from Chicago will tell you, who advocate that you doctors take into your hands the system by which the poor could be cared for, hospitalization provided for, a system of guardianship so secure that the individual can be counted on at all times to be taken care of, however poor, however unfortunate. You say "As patient?" Your friend Lewis says "No." I dismiss the thought of patient, much as I know you have to carry it. I am compelled to tell you that government is on its way to saying to you "Hold up here, Mr. Doctor, we are not asking you to do anything about a patient. Where do you get this that we hear about that we are daring to interfere with your personal relations between you and your patients? We know nothing of patient, don't recognize its existence. It is your creation. We recognize an instrument called citizen who is essential to the welfare of government. He takes the form of man or woman. You have professed to be able to help him carry on his life. We need his life for usefulness in civil affairs, for the conduct of affairs of life in its civil nature, in military for the defense of his nation. And now since you assume to take care of the mother of that child that is to come forward and the mother herself that is to give birth to and help guide it, and the father who must help maintain and sustain it, we are compelled to tell you that we have got to treat you as an officer of the federal government and turn you into being such and ask you to consider the subject of yourself as an official of the federal government taking care of the citizen."

Then, since that is the position in which you are going soon to be put and which every hour you reach nearer and nearer, pardon me if as a brother professional man it is nothing less

than absurd for men to come around you and say "This is an invasion, it ought to be resisted, it ought to be resisted, it ought not to be adopted."

Your answer is "It may be you are right, but it is the policy that seems to possess mankind in his advances all over the world, and since it is to us to be acted upon, Lewis has come down to make this suggestion."

Gentlemen, I desire to reverse the situation. An amendment is now pending. I have had it hung up as like on a hook so I could come down and chat with you. I want the position wholly changed. Instead of the government taking charge of directing the doctor as to what is to be done in the matters where his science is of first application, I want the government to place the doctor in the position where he can direct the government.

Two things are ahead of you, brethren. You come down where I am and listen to the quiet and silent chat and then the whispered voice that beseeches you please not to communicate them as the source of your information; contemplate the movement already afoot by certain well meaning gentlemen who fear some other gentleman and who suggest to your representatives in public life the necessity of picking out certain favorites and constituting them as a body that shall have the full control of your great profession in order to tell each where they shall act, how they shall act, in what manner they shall act, and in every manner they shall serve. Come down close and find out how severe it is we have to contest against that and find oftentimes we are charged with ill manner because we don't wish to have those things whispered to us quietly to be put into the law without some voice to the general profession.

That brings me to say to you it is my judgment that the time is come when you have got to say to yourself "We were willing, and have been as members of organization, to do charity everywhere. We have been doing it for constant years. We pay out of our pocket for the medicine. We tender such services as we can. We give our hours at the expense of other patients to whom we owe an obligation. We join wherever we can in the local government or the state government in every form possible. We obtain no compensation. We have no manner of receiving it. We lose that which we could have made from other sources. And you, Mr. Government, while you have been busy considering what you feel should be the welfare of the needy, you have given no thought as to the rights of the individual you enforce to serve the needy."

Where, then, does that doctor stand?

Physicians, I have a proposition which I take the liberty to give to you, for it is on that that I ask that at some subsequent time you will be so good as to consider that I might through the offices have the benefit of your suggestion. It is that which I feel our committee, knowing that I am to come before you, is expecting to hear from. *I am pleased to tell you that as I left I called the President and told him I was on my way to have a conversation with you gentlemen. I would like to deliver from the President of the United States a message coming direct with his authority. He said that I was authorized to say to you he knew something of your meeting, he had been for some time observing the courses of the doctor, that he was not far removed from constantly keeping up with the features of the profession, and he wished you success as to your undertaking. If I use his exact words, he hoped that you would find a way to cooperate with him in such method as you would jointly find would be to the service of the helpless and the afflicted within such province as you felt government should undertake.* I deliver the message of the President and assure you it was a source of great pleasure that he understood I was to be here.

And here I take the liberty now to define to you what I propose should be the course as to yourselves. That I see that you are advancing to be treated as a federal official there can be no doubt; that you are on the way so soon as you qualify as a doctor in your state and your local situation, to be soon made a member enlisted in those of the profession of the federal government, and as such to be put something in the position of a captain and officer of the army and the navy. You are to be put in the position as one who is to be recognized by the government and subject to the service of the government in protecting your fellow citizen, but in the meantime I trust recognized as having your own rights which at the time may be properly preserved and guarded.

May I offer you the suggestion I have pending. I feel it is most fair to say to a doctor "Doctor, please step out from your business or family." You have children, too, and they ought to be educated; you have homes to be cared for; you have a profession to maintain; you have a prestige to uphold. I don't feel it is right, sir, despite all these attitudes of mind you get from those who have not had time to think upon it to say "Please step aside from all of this, sir, and give your time wholly and largely to the instrumentality necessary to aid those in distress and see they are lifted from it, cared for, hospitalized, medicine provided, in care and watchfulness day after day, and while it is at the expense of yourself financially and in all respect perfected, you owe it."

"To whom?"

"You owe it to what is called society."

"Am I not one of them?"

"One of what?"

"One of the thing you call society."

"Yes."

"Well, is nothing owing to me? Who paid for this education I have? Who paid for the years in which I have gone to obtain it? Who is likely to take care of those whom I am supposed to be maintaining? In the meantime, what effort is being made at least to recognize me as being one of this society in having something of the similar rights of those to whom you now send me to give my whole time and devotion?"

Therefore, dear gentlemen, I will with your consent when you have later given it consideration, if you feel it is agreeable, press on this branch that happens to be mine which I serve (you know what is called chairman of a subcommittee) that I want the present Social Security Law amended. There are amendments pending. You gentlemen too well know that the law is not new and there will be many changes. There are many eminent doctors who feel the Swedish method should be taken up by us and practically adopted, some others the German, that which prevails in Denmark, and interesting to add there is a system of which I knew absolutely nothing which seems to come from China. But the suggestion is that nevertheless you be placed in the position of complete obedience to whatever the law may enforce. I say I want that poor, that afflicted, that suddenly injured, having no funds, unable to make his private, individual contract, to have the right to summon any doctor all around him, however high, however elevated, without regard to what his elevation is, the quickest, the nearest to him for service; that doctor at once turns to the obedience of the demand, to the obedience of the need, and this patient is taken charge of at once as if he had been employed by a paying patient. He promptly sees the need of this patient for hospital, and to the extent that the patient needs the hospital this doctor has a right by virtue of the fact that he is now a federal auxiliary to step into any hospital of any kind at once and have this person attended according to the need as the doctor sees it.

And then what shall follow? It is that on which I am having my discussion. I insist that that doctor, chosen as he is at any time by any one in this need, shall have promptly the right to write down his bill, his exact charge, what he feels with his sense of honor is a fair charge for the service he is doing the patient, for the service he is giving at the hospital, for the medicine he may have to more or less if not credit for be responsible for, and he frames this charge in an intelligible, simple manner, in an ordinary bill. He takes this bill by himself or by mail or by his messenger at once to the agency where this doctor serves who represents the social service and has this bill promptly filed. He may have to repeat this a dozen times a week, he may have to do it a hundred times a month, but wherever he does this work he sends his bill for this work (I come back to you now) not to the patient but to the government whose citizen you are protecting, whose agency and power and force are needed for the carrying on of the thing they call the society you are preserving. With this bill so sent in, you promptly are paid on the theory that, of course, you would not defraud your government, but with a provision in the law that any doctor who could descend to take advantage in the way of price or misrepresentation be treated like any other fraud, and any patient who represented being unable to pay and took advantage of the doctor, taking

his services as well as from the government, be likewise treated as a direct instrument of the fraud and offense against the government; and that by this system we openly announce and we publicly proclaim that doctor as having the right to practice as an immediate representative of the federal government in whatever he attempts to do in behalf of that particular being and instrument called the citizen; that his compensations be so arranged and that he arrange them in such manner consistent with his own sense of honor and proportionate with what he knows has been the service he has been giving.

And now, dear friends, I conclude. As you know from my remarks, I am a lawyer—not always successful. I have had the usual difficulties, the ups and downs that usually follow, but I have not been without experiences in connection with your distinguished profession in many different degrees. I do not think it wise that you doctors should have this system of your compensations put under the control of gentlemen who are to be appointed to be in control of the board and to be given the domination of these privileges as an opportunity for political office. I have seen lately, and I mean nothing unkind—I am speaking to my brethren of the profession in the sense of our respect for each other, and have watched attendance to the poor creatures victims of the World War and have seen something of the service administered to them and the methods of its administration through those who are appointed as political office appointees, and those appointees, meaning ever so well, let it be understood, in all government without regard of politics of any nature. I have watched it day by day grow to where they have so imposed on the government and unhappily the victims of the disease and disorder until the whole thing has been converted into a political machine that has worked a persecution on the afflicted and a robbery on the citizen. I can't see how that can any longer continue among an intelligent body and a patriotic order of citizen. I therefore, my brethren, can't accept—until I get better advice I decline to accept—that this board that is to be constituted is to be made up of political appointees called Democrats or Republicans or whatever designation you please, whose mere political appointees shall have the right to name those who shall sit as to your amount of fees, have a right to revise your bill, consider your services, passing judgment and review on them. I cannot accept it.

I want consideration from you when you have time to reflect on it. What method would you suggest to us in one of complete fairness to you, to your profession, of a system of appointees who shall be those who shall sit in judgment on your fees, the methods of your payment, and, if you please, sometimes the quantity and quality of it? And who is it that shall sit to decide as to each of these geographic localities what particular boards shall in that locality make the board to which you must send your bill and from whom you must take your direction or counsel?

What method do you advise by which you shall not be put out of your character as doctors and subjected to merely a set of servants under the orders of those who call themselves political appointees? I can't take the latter. I am in revolt, and I burden you by coming over here and asking that I may be heard, because on this particular feature I am so much at variance with many around me that I fear I must confide to you that there is a great deal of distraction, almost sometimes amounting to violence in dispute.

I want you to take this subject in hand. There is the law. It is very deficient. Many of the principal features of the right to enter into the subject at all over the state and the government, I might say, of your offices, your duties, was very much debated. That is past the time. The question for you and which I am seeking is how to deal with the doctor, what to do with his profession, what to do with his science that he has equipped himself to discharge, and it is that that I have come to seek from you that you take charge of the subject and give advice to your government, that you please offer counsel to us, as to what in justice to your whole profession first would be the best system to put into effect some organization that shall have the voice with the doctors dealing with the doctors. Second, what shall be the qualification apart from the doctors. Of character or of experience, if you have it, of those who will serve on the board in order to be those who directly serve to the local board? In other words, dear gentlemen, your principal board in Washington I am worried about. I

don't want it made up of gentlemen appointed merely because they may have been effective in stuffing some ballot box. Nor do I want that other set who are to be rewarded for vigorous party service, however sincere, but whose knowledge of medicine consists of that which a hen would have of a neighbor about to pick up her lunch. I want some system that will assure that man who is on the way to serve that patient that he is going to be treated by those who know the value of what he is doing, on the one hand, the service of what he is doing, and that he too be protected by his government as one of those citizens and patriots that they are seeking to preserve.

Citizens, you have a great opportunity and before you a great authority. It is for you to say whether this great system of humanity is to be successful or whether you shall shrink again out of a sense of modesty and not wishing to touch public affairs allow it to drift to where it will be handled by those for political objects or other purposes that shall destroy its great usefulness. It is to you we who are public characters and public agencies in your line must look.

On motion of Dr. H. H. Shoulders, Tennessee, duly seconded and carried, the House gave a rising vote of thanks to Senator Lewis for the expressions he brought.

At 12:05 p. m. the speaker declared the House in recess until 1 p. m.

Fourth Meeting—Thursday Afternoon, June 10

The House of Delegates was called to order at 1:50 p. m. by the Speaker, Dr. N. B. Van Etten.

Report of Reference Committee on Credentials

Dr. B. F. Bailey, Chairman, reported that there was a total registration of 168, which was only four below the possible number that could be registered.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of the Minutes

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. J. E. Paullin, Section on Practice of Medicine, and carried, that the House dispense with the reading of the minutes.

Resolution on Address of Senator J. Hamilton Lewis

Dr. C. W. Roberts, Georgia, presented the following resolution, which was adopted on motion of Dr. Roberts, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried:

Resolved, That the illuminating address of Senator James Hamilton Lewis be referred to the Board of Trustees for consideration and for subsequent reference to the House of Delegates if, in its wisdom, consideration by the House is deemed to be necessary.

Report of the Board of Trustees

Dr. Rock Sleyster, Chairman, presented the following report, which was adopted on motion, seconded by Dr. A. T. McCormack, Kentucky, and carried:

The Board of Trustees reports favorably on the creation of a Council on Industrial Health and, with the approval of the House of Delegates, will proceed with the organization of the Council as a committee of the Board.

Report of Reference Committee on Medical Education

Dr. F. S. Crockett, Chairman, presented the following report: After further conference with many of those interested in defining the services to be rendered under contracts for group hospitalization, your reference committee believes that for the purposes contemplated in the Resolutions on Clarifying the Policy of the American Medical Association on the Question of Group Hospitalization, introduced by Dr. C. W. Stone in behalf of the Ohio State Medical Association, it is advisable to define hospital facilities rather than to attempt a comprehensive definition of medical practice.

It is recommended, therefore, that the contract benefit provided by group hospitalization insurance should be limited to the room, bed, board, nursing facilities ordinarily provided by hospitals, and routine medicines.

Your reference committee would refer to the report of the Board of Trustees as it appears in paragraph 4, page 83, of the Handbook, which was adopted by this House of Delegates yesterday. In that paragraph the limitations of hospital service are well defined. Your reference committee reaffirms this definition of hospital care and recommends its application to contracts for group hospitalization. In regard to certain benefits offered by many hospital insurance plans, combining professional and technical services, your reference committee is in complete sympathy with those who would make every possible provision to prevent inclusion of any and all types of service involving medical care.

It is the opinion of your reference committee that further conference between interested medical groups and the American Hospital Association would be of definite value in clarifying the twilight zone between hospital service and medical care.

Your reference committee has carefully considered the Resolution on Average Daily Census in Hospitals that had been presented by Dr. Henry A. Luce, Michigan, asking "That the House of Delegates of the American Medical Association direct the Council on Medical Education and Hospitals to approve hospitals meeting the requirements of the American Medical Association which have a daily census of fifty."

After extended conference with the Michigan delegation, your reference committee would recommend that the House of Delegates recommend to the Council on Medical Education and Hospitals that the daily average census of seventy-five might be waived in those hospitals which otherwise conform to the present standards and which, in the judgment of the Council, present exceptional opportunities for intern training.

Respectfully submitted.

F. S. CROCKETT, Chairman.
GEORGE BLUMER.
J. T. CHRISTISON.
C. A. DUKES.
W. E. VEST.

On motions, duly seconded and carried, the report of the reference committee was adopted section by section and as a whole.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. J. N. Baker, Chairman, presented the following report:

Your reference committee recommends the approval of the following resolution embodying a proposed amendment to the Principles of Medical Ethics:

Resolved, That the Principles of Medical Ethics, Chapter III, Article 6, New Section 3, be amended by the addition to paragraph 2 of the following:

The phrase "free choice of physician," as applied to contract practice, is defined to mean that degree of freedom in choosing a physician which can be exercised under usual conditions of employment between patient and physician when no third party has a valid interest or intervenes. The interjection of a third party who has a valid interest or who intervenes does not per se cause a contract to be unethical. A "valid interest" is one where, by law or necessity, a third party is legally responsible either for cost of care or for indemnity. "Intervention" is the voluntary assumption of partial or full financial responsibility for medical care. Intervention must not proscribe endeavor by component or constituent medical societies to maintain high quality of service rendered by members serving under approved sickness service agreements between such societies and governmental boards or bureaus and approved by the respective societies.

Respectfully submitted.

J. N. BAKER, Chairman.
C. H. GOODRICH.
G. P. JOHNSTON.
V. E. SIMPSON.
T. F. THORNTON.

The report of the reference committee was adopted, on motion of Dr. Baker, seconded by Dr. Charles H. Goodrich, New York, and carried.

On motion of Dr. H. A. Luce, Michigan, seconded by Dr. L. J. Hirschman, Michigan, and carried, the Principles of Medical Ethics were amended as recommended by the reference committee.

Report of Reference Committee on Miscellaneous Business

Dr. J. D. Brook, Chairman, presented the following report, which was adopted on motion of Dr. Brook, seconded by Dr. John J. Masterson, New York, and carried:

Your reference committee, to which was referred the Resolution on Evils from Promiscuous Use of Barbituric Acid and Derivative Drugs, introduced by Dr. H. A. Luce, Michigan, is informed from the report of the Board of Trustees on page 67 of the Handbook that only fourteen of the forty-eight states have laws governing the sale of these drugs and believes that, to obviate criticism from laymen and attorneys in states not having controlling laws, the resolution is timely.

Your reference committee therefore recommends that the resolution be referred to the Board of Trustees, with the request that the Bureau of Legal Medicine and Legislation take such steps as in its judgment seem proper to bring the use of these drugs under governmental control, as requested in the resolution.

Respectfully submitted.

J. D. BROOK, Chairman.
H. L. BRYANS.
WALT P. CONAWAY.
C. S. SKAGGS.
C. W. WAGGONER.

Resolutions from Section on Ophthalmology Dealing with Action of Social Security Board Relative to Applicants for Blind Assistance

Dr. Arthur J. Bedell, Section on Ophthalmology, presented resolutions, which were amended to read as follows, and which were adopted, on motion of Dr. Bedell, seconded by Dr. E. J. Best, California, and carried:

WHEREAS, The Federal Social Security Act in Title Ten has placed on the Social Security Board the responsibility of entering into cooperative arrangements with the various states for the purpose of aiding those states in granting financial assistance to needy blind individuals and has ruled that individuals in the various states who apply for blind assistance must be examined by an ophthalmologist or a doctor of medicine skilled in diseases of the eye; and

WHEREAS, The Social Security Board has advised the official state agencies that have the responsibility of administering this aid in those states to employ a supervising ophthalmologist who will have general supervision over the medical determination of blindness within the state; therefore be it

Resolved, That the Section on Ophthalmology of the American Medical Association approves the action of the Social Security Board in requiring that applicants for blind assistance within the various states be examined by a regularly licensed and registered doctor of medicine skilled in diseases of the eye or by an ophthalmologist, as such a procedure will serve to secure a fuller knowledge as to the causes of blindness within the United States; and be it further

Resolved, That the Section on Ophthalmology of the American Medical Association goes on record as approving the suggestion of the Social Security Board that the official agency in the state or territory charged with the responsibility of administering blind assistance employ a supervising ophthalmologist whose duty will be the general supervision of the medical determination of blindness of those needy individuals applying for blind assistance; and be it further

Resolved, That the delegate from the Section on Ophthalmology of the American Medical Association be and is hereby instructed to present these resolutions to the House of Delegates.

Resolution from the Section on Nervous and Mental Diseases Dealing with Psychiatric Research

Dr. H. H. F. Reese, Section on Nervous and Mental Diseases, presented the following resolution, which was adopted on motion of Dr. Reese, seconded by Dr. J. Allen Jackson, Pennsylvania, and carried:

WHEREAS, Several organizations interested in promoting human welfare have manifested a deep interest in research into the causation, prevention and treatment of mental disease and have furnished substantial financial aid to the prosecution of such research; and

WHEREAS, The Rockefeller Foundation, the John and Mary R. Markle Foundation, the Josiah Macy Jr. Foundation and the Supreme Council of the Scottish Rite of Freemasonry for the Northern Masonic Jurisdiction have been outstanding in giving moral and financial support to such research; be it

Resolved, That the House of Delegates of the American Medical Association, on behalf of American psychiatry, hereby records its gratitude for the valuable service rendered to the cause of psychiatric research by these organizations and that it heartily endorses the importance of studies looking to a solution of the problems of mental disease.

Address of Mr. R. Watson Jones

The Speaker introduced the official representative of the British Medical Association, Mr. R. Watson Jones, who addressed the House as follows:

Mr. Speaker and Gentlemen: I have the great honor to represent the British Medical Association and to bring from England a cordial expression of good will and good fellowship

to the American Medical Association. Wherever I travel in America my pulse is stirred by the warmth of the greeting and by the sincerity of the hospitality which you have shown to a British surgeon. You must know and believe that we in England have an equally warm regard for our friends on this side of the Atlantic. We are eager and anxious to cooperate with you and, if we can, to fuse the stability of Great Britain with the progress of America.

In these days of industrial disturbance and of economic and political strife, the great English speaking nations must work together for the peace of the world. It has been a short time since American surgeons made a great sacrifice and came over to England to cooperate with British surgeons in the catastrophe of twenty years ago. God protect us from another such catastrophe. It is, however, well to remember that in our service to humanity, in our attempt to relieve suffering, we can work together side by side. The great arts, science, music, medicine, know no bounds of nationality; these are given to mankind; they are of service to the world, and if every physician and every surgeon works with this as his objective, when his work is done it may be said of him, as John Drinkwater said of Abraham Lincoln, "Now he belongs to the ages."

Mr. Speaker, on behalf of Great Britain I bring a very cordial greeting from the British Medical Association to the American Medical Association.

ELECTION OF OFFICERS

Dr. Olin West, Secretary, on request of the Speaker, read Sections 1 and 3, Chapter IV, of the By-Laws referring to nominations.

The Speaker appointed as tellers Drs. W. H. Mock, Arkansas, Chairman; E. S. Hamilton, Illinois; Walter A. Lane, Massachusetts; T. R. K. Gruber, Michigan, and E. L. Henderson, Kentucky.

Election of President-Elect

Dr. Arthur T. McCormack, Kentucky, nominated for President-Elect Dr. Irvin Abell, Louisville, Ky., and the nomination was seconded by Drs. J. E. Paullin, Section on Practice of Medicine; Joseph F. Smith, Wisconsin; Terry M. Townsend, New York; J. H. O'Shea, Washington; Ephraim R. Mulford, New Jersey; A. A. Walker, Alabama; E. G. Wood, Tennessee; Samuel P. Mengel, Pennsylvania, and the Pennsylvania delegation unanimously; C. W. Roberts, Georgia, for the Georgia delegation; Herbert L. Bryans, Florida; Charles A. Dukes, California; Horace Reed, Oklahoma; Felix J. Underwood, Mississippi, and Holman Taylor, Texas, for the Texas delegation.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, duly seconded and carried, that the nominations be closed.

Dr. J. W. Burns, Texas, moved that the Secretary be instructed to cast the unanimous ballot of the House for Dr. Irvin Abell as President-Elect. The motion was seconded by Dr. E. R. Mulford, New Jersey, and carried.

The Secretary cast the vote of the House for Dr. Irvin Abell, Louisville, Ky., as President-Elect of the American Medical Association for the ensuing year, and the Speaker declared Dr. Abell so elected.

Election of Vice President

Dr. Robert A. Peers, California, nominated for Vice President Dr. Junius B. Harris, Sacramento, Calif., and the nomination was seconded by Dr. B. F. Bailey, Nebraska, and Dr. Gunnar Gundersen, Wisconsin.

On motion of Dr. Harry H. Wilson, California, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, the nominations were closed.

It was moved by Dr. B. F. Bailey, Nebraska, seconded by Dr. J. Gurney Taylor, Wisconsin, and carried, that the rules be suspended and the Secretary be instructed to cast the ballot of the House for Dr. Junius B. Harris as Vice President.

The Secretary cast the ballot of the House for Dr. Junius B. Harris, Sacramento, Calif., as Vice President of the American Medical Association for the ensuing year, and the Speaker declared Dr. Harris so elected.

Election of Secretary

Dr. Horace Reed, Oklahoma, nominated Dr. Olin West, Chicago, to succeed himself as Secretary of the American Medical Association, and the nomination was seconded by Dr. Charles A. Dukes, California. The nominations were closed on motion of Dr. B. F. Bailey, Nebraska, seconded by Dr. E. J. Best, California, and carried.

It was moved by Dr. B. F. Bailey, Nebraska, seconded by Dr. J. E. Paullin, Section on Practice of Medicine, and carried unanimously by a rising vote, that the rules be suspended, that the Speaker be instructed to cast the ballot for Dr. West and that the members be asked to signify their vote by rising.

The Speaker cast the ballot of the House for Dr. Olin West as Secretary of the American Medical Association and declared him elected Secretary for the ensuing year.

Election of Treasurer

Dr. Rock Sleyster, Chairman of the Board of Trustees, stated that the Board of Trustees nominated Dr. Herman L. Kretschmer, Chicago, as Treasurer. The nomination was seconded by Dr. Harold T. Low, Colorado. The nominations were closed on motion of Dr. G. Henry Mundt, Illinois, seconded by Dr. Robert A. Peers, California, and carried.

Dr. W. F. Braasch, Minnesota, moved that the Secretary be instructed to cast the ballot of the House of Delegates for Dr. Herman L. Kretschmer, Chicago, as Treasurer. The motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried. The Secretary cast the vote of the House for Dr. Herman L. Kretschmer, Chicago, as Treasurer for the ensuing year, and the Speaker declared Dr. Kretschmer so elected.

Election of Speaker of the House of Delegates

The Vice Speaker, Dr. H. H. Shoulders, took the chair and announced that the next order of business was the election of a Speaker of the House of Delegates.

Dr. Floyd S. Winslow, New York, nominated for Speaker Dr. N. B. Van Etten, New York. The nomination was seconded by Dr. Joseph F. Smith, Wisconsin.

The nominations were closed on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Charles A. Dukes, California, and carried.

On motion of Dr. H. L. Snyder, Kansas, seconded by Dr. Charles A. Dukes, California, and carried, the Secretary cast the ballot of the House for Dr. N. B. Van Etten, New York, as Speaker of the House of Delegates for the ensuing year. The Vice Speaker declared Dr. N. B. Van Etten duly elected Speaker of the House of Delegates.

Address of President-Elect Irvin Abell

The Speaker presented the President-Elect, Dr. Irvin Abell, Louisville, Ky., who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates:

I find my vocabulary quite inadequate to express to you the depth and the strength of my appreciation of the honor which you have done me and the state association of which I am a member in designating me as your President-Elect, the most signal honor in your power to bestow.

I look back on the many years of service in this House of Delegates as not only one of the happiest experiences of my professional career but one of the most inspiring. I have had the opportunity of drinking from the cup of knowledge, always kept filled to the brim with your policies of statesmanship; I have derived untold inspiration from your fellowship and your friendship, from your fidelity, your courageous spirit and your judgment in dealing with the problems of American medicine. As I look back over these years I see that the welfare and the health of the people whom we serve have ever been dominant factors in your efforts to furnish to the people of this country the highest medical service obtainable.

With a sense of my own shortcomings I accept in all humility this evidence of the confidence which you repose in me, with a full realization of the obligations and the responsibilities it entails, and at the same time with the firm determination so far as it lies within my power to walk faithfully in the footsteps of the distinguished men whom in years gone by you have so honored.

Election of Vice Speaker of the House of Delegates

The Speaker, Dr. N. B. Van Etten, resumed the chair and declared the next order of business to be the election of a Vice Speaker of the House of Delegates.

Dr. H. B. Everett, Tennessee, nominated for Vice Speaker Dr. H. H. Shoulders, Nashville, Tenn., and the nomination was supported by Dr. J. F. Hassig, Kansas, and Dr. Charles H. Goodrich, New York.

On motion of Dr. Horace Reed, Oklahoma, seconded by Dr. H. B. Everett, Tennessee, and carried, the nominations were closed.

Dr. G. Henry Mundt, Illinois, moved that the Secretary cast the vote of the House for Dr. H. H. Shoulders as Vice Speaker of the House. The motion was seconded by Dr. Harry H. Wilson, California, and carried. The Secretary cast the ballot of the House of Delegates for Dr. H. H. Shoulders, Nashville, Tenn., as Vice Speaker of the House of Delegates for the ensuing year, and the Speaker declared Dr. Shoulders elected Vice Speaker.

Election of Trustees

The Speaker declared the next order of business to be the election of two Trustees each to serve for a term of five years, and stated that the Trustees whose terms expire this year are Dr. Arthur W. Booth, Elmira, N. Y., and Dr. Rock Sleyster, Wauwatosa, Wis. He called for nominations for a Trustee to succeed Dr. Arthur W. Booth.

Dr. Frederic E. Sondern, New York, nominated Dr. Arthur W. Booth, Elmira, N. Y., to succeed himself as Trustee, and the nomination was supported by Drs. E. R. Mulford, New Jersey; E. H. Cary, Texas; J. Gurney Taylor, Wisconsin; Arthur T. McCormack, Kentucky; J. D. Hamer, Arizona; J. Newton Hunsberger, Pennsylvania, and Walter R. Steiner, Connecticut.

The nominations were closed on motion of Dr. E. R. Mulford, New Jersey, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, and the Secretary was instructed to cast the vote of the House for Dr. Arthur W. Booth, Elmira, N. Y., as Trustee, on motion of Dr. E. R. Mulford, New Jersey, seconded by Dr. Samuel F. Mengel, Pennsylvania, and carried.

The Secretary cast the ballot of the House for Dr. Arthur W. Booth to succeed himself as Trustee for a term of five years, and the Speaker declared Dr. Booth elected Trustee.

The Speaker declared the next order of business to be the election of a Trustee to succeed Dr. Rock Sleyster, Wauwatosa, Wis., whose term expires this year and who, according to the By-Laws, is not eligible for reelection.

Dr. F. S. Crockett, Indiana, nominated Dr. R. L. Sensenich, South Bend, Ind., and the nomination was seconded by Drs. H. L. Snyder, Kansas; Arthur T. McCormack, Kentucky; G. Henry Mundt, Illinois; Frederic E. Sondern, New York, on behalf of the New York delegation; J. Gurney Taylor, Wisconsin, and Arthur C. Morgan, Pennsylvania.

Dr. E. J. Best, California, moved that the nominations be closed, and the motion was seconded by Dr. J. J. Moore, Section on Pathology and Physiology, and carried.

On motion regularly made, seconded and carried, the Secretary cast the ballot of the House for Dr. R. L. Sensenich, South Bend, Ind., to succeed Dr. Rock Sleyster as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. Sensenich so elected.

Nominations for Standing Committees

Dr. J. H. J. Upham, President, submitted the following nominations for standing committees:

Judicial Council: Dr. John W. Burns, Cuero, Texas, to succeed Dr. Lloyd Noland, for a term ending in 1942.

Council on Medical Education and Hospitals: Dr. Charles Gordon Heyd, New York, to succeed Dr. Charles E. Humiston, for a term ending in 1944.

Council on Scientific Assembly: Dr. Clyde Cummer, Cleveland, to succeed Dr. Frank H. Lahey, for a term ending in 1942, and Dr. J. Gurney Taylor, Milwaukee, to fill the unexpired term ending in 1939 of Dr. Irvin Abell, who had been elected President-Elect of the American Medical Association.

On motions duly made, seconded and carried, each nomination was confirmed by the House of Delegates.

Election of Honorary, Affiliate and Associate Fellows

NOMINATION FOR HONORARY FELLOWSHIP

The Secretary submitted the nomination for Honorary Fellowship of Dr. Erich Hoffmann, Bonn, Germany, submitted by the Section on Dermatology and Syphilology and approved by the Council on Scientific Assembly.

APPLICANTS FOR AFFILIATE FELLOWSHIP APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

Bill, B. J., Genoa City, Wis.
Bobo, C. S., Norman, Okla.
Bryant, William S., New York.
Cobb, Albert C., Boston.
Denton, Myron P., New York.
Dolloff, A. S., New Hampton, N. H.
Grady, Henry D., Miami, Mo.
Greene, Edward M., Boston.
Hansell, William, Ottumwa, Iowa.
McCready, Joseph W., New York.
Nourse, Robert L., Boise, Idaho.
Numbers, Joseph R., Boise, Idaho.
Ramsay, R. Warren, York, Pa.
Richey, Sidney M., Tulsa, Okla.
Small, Charles P., Chicago.
Spilman, S. A., Ottumwa, Iowa.
Stickney, Henry L., Sunmount, N. Y.
Turnbull, Thomas, Jr., Casanova, Va.
Warren, N. A., Yonkers, N. Y.
Wilson, H. P., Wynnewood, Okla.

APPLICANTS FOR ASSOCIATE FELLOWSHIP FROM AMERICAN MEDICAL MISSIONARIES APPROVED BY THE JUDICIAL COUNCIL

McAnlis, William W., Legaspi, Albay, P. I.
Rost, Glenn Simon, Beirut, Syria.

APPLICANTS FOR ASSOCIATE FELLOWSHIP NOMINATED BY THE SECTIONS INDICATED

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

Downs, William Gershon, New York.
Urban, Walter George, Pittsburgh.

PEDIATRICS

Kato, Katsuji, Chicago.

PHARMACOLOGY AND THERAPEUTICS

Nelson, Erwin, New Orleans.

PATHOLOGY AND PHYSIOLOGY

Bing, Franklin Church, Evanston, Ill.
Dore, Francis J., Chestnut Hill, Mass.
Queen, Frank B., Denver.

GASTRO-ENTEROLOGY AND PROCTOLOGY

Bollman, Jesse L., Rochester, Minn.

On motions duly made, seconded and carried, the nominations were approved and the nominees declared elected Honorary, Affiliate or Associate Fellows as indicated.

Place of 1938 Annual Session

The Speaker announced that the next order of business was the selection of the place and the fixing of the time of the 1938 annual session and called on the Board of Trustees for nominations.

Dr. Rock Sleyster, Chairman of the Board of Trustees, presented the following report:

Mr. Speaker, an invitation has been received to hold the 1938 annual session in San Francisco. The invitation is signed by the San Francisco County Medical Society, the California Medical Association, the mayor of San Francisco and the San Francisco Convention and Tourist Bureau. The facilities of San Francisco have been personally checked by the Secretary, the Business Manager and the Chairman of the Board and have been found to be adequate.

Dr. W. E. Kittler, Illinois, moved that the Association hold its 1938 annual session in San Francisco, and the motion was seconded by Dr. Arthur T. McCormack, Kentucky.

Dr. E. J. Best, California, extended an invitation from the medical profession in San Francisco and in California to have the Association meet in San Francisco in 1938.

Dr. Charles W. Stone, Ohio, in supporting the motion to meet in San Francisco in 1938, extended an invitation to have the Association meet in Cleveland in 1939.

Dr. Walt P. Conaway, New Jersey, invited the Association to meet in Atlantic City, N. J., in 1939.

The motion to have the Association meet in San Francisco in 1938 was carried, and the Speaker declared that San Francisco had been selected for the 1938 annual session of the American Medical Association.

Messages of Appreciation

The Vice Speaker took the chair and Dr. J. Newton Hunsberger, Pennsylvania, moved a vote of thanks and appreciation to the local committee on arrangements at Atlantic City for its splendid session, and the motion was amended to include an expression of appreciation and gratitude to the Speaker for the able work he has done and the courtesy he has extended to every member of the House of Delegates. The motion as amended was seconded by Dr. E. J. Best, California, and carried.

The Speaker resumed the Chair, and Dr. Harry H. Wilson, California, moved that a rising vote of thanks be extended to Dr. Rock Sleyster, retiring trustee, for his years of service to the Association. The motion was unanimously carried.

Communication from Citizens Committee for Support of WPA

The Secretary presented the following communication, which was referred to the Board of Trustees, on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded and carried.

House of Delegates of the
American Medical Association
in convention at
Atlantic City, New Jersey.

Attention of Dr. Charles Gordon Heyd, President
Gentlemen:

The Citizens Committee for Support of WPA wishes to express its commendation of your recognition of the principle that the health of the people is a direct concern of government. The sentiment of your Association in this regard will not fail to exert a powerful influence on public policy.

May we invoke this influence in the immediate interests of the health of the workers, to the number of from 600,000 to 1,000,000 who face momentary layoff from the WPA according to announcements of Administrator Harry L. Hopkins in the last two weeks.

To you as medical scientists, we cannot appeal from the sociological or the economic points of view, although we believe that these layoffs will be an incalculable economic and sociological disaster.

But we feel justified in appealing to you from a purely medical point of view, to endorse our principle: that if private employment is able to absorb the workers about to be laid off from WPA (which is not even claimed by the administration) then at least the "absorption" should be ensured to each worker before he is laid off.

For members of our committee have seen evidence of the havoc which previous layoff waves, of lesser scope, have wreaked upon the health of those laid off, and of their dependents, in the signed affidavits of dozens of physicians which were submitted to the administration when the damage had been done.

We feel justified also in anticipating your regret at the impending curtailment of the benefits of the many (yet still too few) medical projects of the WPA: of the nine million treatments and visits; the dental treatments to 386,000 children in New York City alone; the millions of inoculations and vaccinations against scarlet fever, diphtheria, influenza, typhoid, whooping cough, smallpox; the other medical care and laboratory research covering maternity, infant welfare, cardiac, hookworm, poliomyelitis, and tubercular fields, all reported by the administration in its official release of May 1.

May we urge you to take the opportunity, in your influential sessions, to record your sentiment against this curtailment, and to endorse the principle embodied in P4 above.

With most sincere respects,
BURRELL FREDMAN,
Acting Secretary.

Committee on Distinguished Service Awards

The Speaker, in accordance with instructions received from the House of Delegates to appoint a Committee on Distinguished Service Awards, announced the appointment of the committee as follows:

Drs. H. H. Shoulders, Tennessee, for one year; J. W. Amesse, Colorado, and J. D. Brook, Michigan, each for two years; J. F. Hassig, Kansas, and Grant C. Madill, New York, each for three years.

The House adjourned sine die at 3:30 p. m.

(To be continued)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Society News.—The Navajo-Apache County Medical Society has been dissolved on account of the vast geographic distance entailed for a meeting of the physicians in the two counties. The Apache County Medical Society has been organized as a separate unit, with Drs. Thomas J. Bouldin, St. Johns, and Guy E. Maxwell, Springerville, as president and secretary respectively.

COLORADO

Society News.—E. E. Howell, D.D.S., Grand Junction, discussed "Oral Focal Infection" before a joint meeting of the Mesa County medical and dental societies, May 20, in Grand Junction.—At a meeting of the Northeast Colorado Medical Society in Sterling, May 13, Dr. Alfred M. Wolfe, Denver, discussed heart disease.—Dr. George L. Pattee, Denver, addressed a recent meeting of the Fremont County Medical Society on "Infections of the Head and Neck."—A recent meeting of the Delta County Medical Society was addressed by Dr. Lawrence L. Hick, Delta, on sulfanilamide in the treatment of streptococcal infections.

Midsummer Radiologic Conference.—The third midsummer radiologic conference sponsored by the Denver Radiological Club will be held at the Hotel Shirley-Savoy, Denver, July 15-17, with Dr. William W. Wasson, president of the club, presiding. Dr. Arthur J. Markley, Denver, president of the state medical society, will deliver the address of welcome. A symposium on the breast will be presented Thursday afternoon with the following speakers: Henry C. Tracy, Ph.D., Lawrence, Kan.; Drs. Frederic C. Narr, Ira H. Lockwood, James E. Stowers, Claude J. Hunt, all of Kansas City, Mo., and Lewis G. Allen, Kansas City, Kan. The evening session will be a joint meeting with the Medical Society of the City and County of Denver with Dr. Paul J. Connor, president of the society, presiding. The guest speakers will be Drs. Leo G. Rigler, Minneapolis, on "The Roentgen Examination in Preventive Medicine" and Henry Schmitz, Chicago, "The Selection of the Form of Treatment in Uterine Myomas." Other speakers on the program include:

Dr. Ernst A. Schmidt, Denver, Recent Advances in Diagnostic Radiology.
Dr. Paul C. Hodges, Chicago, Roentgen-Ray Pelvimetry and Cephalometry.
Dr. Leon J. Menville, New Orleans, Roentgenologic Studies of the Gastro-Intestinal Motor Phenomena.
Dr. Paul R. Weeks, Denver, Recent Advances in Radiation Therapy.
Dr. Hayes E. Martin, New York, Diagnosis, Treatment and Curability of Intra-Oral Cancer.

There will be round table discussions on the problems of diagnostic radiology and therapeutic radiology Friday and Saturday and the informal banquet will be held Friday evening at the Venetian Gardens.

CONNECTICUT

State Medical Election.—Dr. Hugh B. Campbell, Norwich, was chosen president-elect of the Connecticut State Medical Society at its annual meeting, May 20, in Bridgeport, and Dr. Charles H. Turkington, Litchfield, was installed as president. Dr. Creighton Barker, New Haven, was reelected secretary. The next annual session will be held in Groton and New London.

Society News.—Dr. Herbert S. Gasser, New York, director of the Rockefeller Institute of Medical Research, discussed "Nerve Fibers" before the Yale Medical Society, May 12.—Dr. Milton C. Winternitz, New Haven, discussed "Pathology of Vascular Disease" before the New London County Medical Association in Waterford, April 1.—At a meeting of the Hartford County Medical Association in Hartford, April 6, Dr. George Baehr, New York, spoke on "Visceral Manifestations of Syphilis."

Kline Exclusion Test Adopted by State Laboratories.—Beginning July 1, the bureau of laboratories of the Connecticut State Department of Health will use the Kline Exclusion Test as a routine test on all blood specimens for syphilis. The change will apply only to specimens of blood; spinal fluids will be tested as at present, it was stated. According to the bulletin of the state department of health, the change will make pos-

sible earlier reporting of specimens needing no further study. The change was agreed on after a study of comparative tests on more than 5,000 specimens.

Public Health Meeting.—The Connecticut Public Health Association held its annual meeting at the Hotel Taft, New Haven, May 26. Drs. Louis J. Dumont, New Britain, president of the society, and Joseph I. Linde, health officer of New Haven, gave opening addresses. Other speakers included:

- Dr. Stanley H. Osborn, Hartford, state health commissioner, New State Public Health Legislation.
- Leslie C. Frank, senior sanitary engineer, U. S. Public Health Service, Practical Methods of Safeguarding Milk Supplies.
- John W. Murphy, mayor of New Haven, Public Health from the Viewpoint of a Mayor.
- Dr. Reginald M. Atwater, New York, executive secretary, American Public Health Association, Today's Trends in Public Health.
- Dr. Henry B. Moyle, director, Hartley-Salmon Clinic, Hartford, Applying What We Know in Mental Hygiene, with Special Reference to Public Health Nursing.
- Dr. Herbert L. Lombard, Boston, director, adult hygiene, Massachusetts Department of Public Health, Lessons from the Massachusetts Cancer Program.

DELAWARE

Society News.—Dr. Ralph M. Tyson, Philadelphia, discussed "Tuberculosis in Childhood" before the New Castle County Medical Society in Wilmington, May 18; Dr. Ralph Pemberton, Philadelphia, spoke April 20 on the treatment of arthritis.

DISTRICT OF COLUMBIA

Medical Bill in Congress.—H. R. 6869 has passed the House, proposing to regulate the practice of cosmetology in the District of Columbia.

Personal.—Comdr. Charles S. Stephenson, medical corps, U. S. Navy, has been detailed as a member of the National Advisory Health Council, replacing Rear Admiral Charles S. Butler, resigned.

Medical Election.—Dr. Thomas E. Neill, Washington, was elected president of the Medical Society of the District of Columbia at its annual session, May 12, and Dr. Coursen B. Conklin, Washington, reelected secretary. The next annual meeting of the society will be held in Washington, May 4-5, 1938.

FLORIDA

Personal.—Dr. C. C. Witt, Arcadia, has been appointed supervisor of district number 2 of the state health department, with headquarters at Lake City.—Dr. Harold C. McDowell, Gastonia, N. C., has been named a member of the staff of the Florida Medical Center, Venice.—Dr. Rollin D. Thompson, medical director and superintendent, Wisconsin State Sanatorium, Statesan, has been placed in charge of the new state tuberculosis sanatorium at Orlando.—Dr. Leonidas M. Anderson, Lake City, was recently appointed inspector of the state institutions and administration advisor by the state board of health.

GEORGIA

District Meetings.—The Fifth District Medical Society held its annual meeting at the Academy of Medicine, Atlanta, April 29. The program was opened with addresses of welcome by Drs. Henry Clifford Sauls, Atlanta, and Benjamin H. Minchew, Waycross, presidents, respectively, of the Fulton County Medical Society and the Medical Association of Georgia. Other speakers were:

- Dr. Frank K. Boland, Atlanta, Pathfinders in Southern Gynecology.
- Dr. Bret Ratner, New York, Various Phenomena of Hypersensitiveness and Management of Asthma and Hay Fever in Children.
- Dr. Edwin C. Hamblen, Durham, N. C., Clinical Value of the Present Preparations of Sex Hormones in Gynecology.
- Dr. Porter P. Vinson, Richmond, Va., Frequent Causes of Dysphagia, with Suggestions as to the Management of Esophageal Obstruction.

At a meeting of the First District Medical Society in Millen recently, the speakers included Drs. Harry H. McGee and Leonard J. Hahne, both of Savannah, on "Some Facts About Lumbosacral Pathology as Revealed by the X-Ray" and "The Maintenance of Body Fluid Balance," respectively.—The Ninth District Medical Society was addressed at Toccoa recently, among others, by Dr. William A. Selman, Atlanta, on postoperative care of acute conditions of the abdomen; Straskernes A. Petroff, Ph.D., Trudeau, N. Y., tuberculosis, and Dr. Benjamin H. Minchew, Waycross.—Among other speakers, Dr. Otis R. Thompson, Macon, spoke on "Toxemia During the Last Trimester of Pregnancy" before the Second District Medical Society at Tifton, April 9, and Dr. Frank E. Thomas, Albany, "Management and Care of the New-Born."—Dr. Wilbur D. Hall, Calhoun, discussed "Mandelic Acid in the Treatment of Urinary Tract Infections" before the

Seventh District Medical Society at Calhoun, April 7, among other speakers, and Dr. George B. Smith, Rome, "The Problems of Cross-Eyed Children."

ILLINOIS

Hospital News.—The Fox River Sanatorium, Batavia, observed its tenth anniversary, May 23, with the opening of its new \$100,000 building. The new structure is two stories high and adds forty-four beds to the sanatorium, which is maintained by the Chicago Consumptive Aid Society.

Fifty Years of Practice.—Dr. Alfred E. Owens, Princeton, was presented with fifty silver dollars at a meeting of the staff of the Perry Memorial Hospital, May 21, in recognition of his completion of fifty years in the practice of medicine. A telegram from the state medical society announced that he had been made a life member. Speakers included Drs. Oliver J. Flint, Princeton; Samuel W. Hopkins, Walnut, and Charles C. Scott, Princeton.

Personal.—Dr. Karl M. Beck has been appointed county physician and superintendent of the Lake County General Hospital, Waukegan, for two years beginning July 1.—Dr. Robinson Bosworth has resigned as medical director of the Rockford Municipal Tuberculosis Sanatorium, effective September 1; it is reported that he is to accept a similar position with the new St. Clair County Tuberculosis Sanatorium, East St. Louis, which is to be erected this summer.—Dr. Donald W. Tripodi has resigned as superintendent of the Livingston County Sanatorium, Pontiac, to engage in private practice in St. Louis, it is reported.—Dr. Pierce A. Steele has been appointed health officer of Decatur, succeeding Dr. Wilmer M. Talbert, who resigned to engage in private practice.—Dr. Alban L. Mann recently completed twenty-five years as health officer of Elgin.

INDIANA

Dr. Carrel Lectures at Dedication.—The medical laboratory and medical building of Ball Memorial Hospital, Muncie, was dedicated April 24. Dr. Alexis Carrel, New York, of the Rockefeller Institute of Medical Research, delivered the dedicatory address on "The Past and the Future of Medical Research." Dr. Carrel was introduced by William Lowe Bryan, Ph.D., president of Indiana University, and Mrs. Edmund Burke Ball made the presentation of the building to the hospital in memory of her late husband. The new unit is one of three which make up the hospital and represent an investment of about \$2,250,000, the gift of the Ball family.

Society News.—Dr. Charles P. Emerson, Indianapolis, presented a "Comparison of Physiological and Psychological Aspects of Eastern and Western Civilizations" before the Delaware-Blackford County Medical Society in Hartford City, April 20.—The Montgomery County Medical Society devoted its meeting, April 22, in Crawfordsville, to a symposium on tuberculosis with Drs. Wemple Dodds, Crawfordsville; Russell S. Henry, Indianapolis, and Paul D. Crimm, Evansville, as the speakers.—Dr. Russell L. Haden, Cleveland, addressed a joint meeting of the Fort Wayne Medical Society and the St. Joseph County Medical Society, April 21, on anemia.—At a recent meeting of the Adams County Medical Society in Decatur, Dr. Frederic G. Maurer, Lima, Ohio, spoke on the etiology, diagnosis and treatment of heart disease.—At a meeting of the Wayne-Union County Medical Society in Richmond, April 29, Dr. Charles O. McCormick, Indianapolis, spoke on "Analgesia in Labor and Modified Gwathmey Technic."—The Elkhart County Medical Society was addressed in Elkhart, April 29, by Dr. Robert M. Moore, Indianapolis, on acute cardiovascular emergencies.—Dr. Robert N. Wimmer, Gary, addressed the Porter County Medical Society in Valparaiso, April 27, on "Newer Points of View in the Treatment of Diarrhea, Intoxication and Dehydration in Infants."—Dr. James J. D. Hoover, Terre Haute, discussed "The Underprivileged Doctor" before the Vigo County Medical Society in Terre Haute, April 13.

IOWA

Personal.—Dr. John E. Wilkinson, Ottumwa, observed his one hundredth birthday, June 6.

Society News.—Dr. Kellogg Speed, Chicago, addressed the Black Hawk County Medical Society in Waterloo, May 18, on "Acute Epiphysitis of the Proximal End of the Femur" and "Everyday Injuries to the Knee Joint."—At a meeting of the Clinton County Medical Society, May 13, Dr. Fredrick A. Willis, Rochester, Minn., spoke on "Diseases of the Coronary Arteries."—The Floyd County Medical Society was addressed in Charles City, May 25, by Dr. Daniel J. Glomset, Des Moines, on "Modern Treatment of Congestive Heart

Failure.—A symposium on cancer was presented before the Harrison County Medical Society in Logan, May 18, by Drs. Francis X. Tamisica, Missouri Valley; Samuel M. Clark, Woodbine; Elmer J. Cole, Woodbine, and Frank H. Hanson, Magnolia. —Dr. William F. Mengert, Iowa City, discussed "Toxemias of Pregnancy" before the Jasper County Medical Society, in Newton, May 4. —The Marshall County Medical Society held its annual summer clinic in Marshalltown, May 26. Dr. Waltman Walters, Rochester, Minn., the principal speaker at the banquet, discussed "Developments in the Management of Lesions of the Biliary Tract." —Dr. Thomas F. Thomsen, Red Oak, spoke on "Management of Diabetes with Protamine Zinc Insulin" before the Montgomery County Medical Society in Villisca, May 27. —A joint meeting of the Pottawattamie and Woodbury county medical societies, May 24, in Council Bluffs, was addressed, among others, by Dr. Raymond J. Harrington, Sioux City, on electrocardiography.

Reunion of Past Presidents.—A reunion of past presidents of the Iowa State Medical Society was a feature at the annual meeting of the society in Sioux City. In attendance at a luncheon in their honor were:

Dr. William Jepson, Sioux City, 1906.
Dr. Walter L. Bierring, Des Moines, 1908.
Dr. Vernon L. Treynor, Council Bluffs, 1913.
Dr. Oliver J. Fay, Des Moines, 1924.
Dr. Frank M. Fuller, Keokuk, 1925.
Dr. Smith A. Spilman, Ottumwa, 1926.
Dr. John H. Peck, Oakdale, 1930.
Dr. Channing G. Smith, Granger, 1932.
Dr. William W. Bowen, Fort Dodge, 1933.
Dr. Charles B. Taylor, formerly of Ottumwa and recently of San Antonio Heights, Upland, Calif., 1934.
Dr. Gordon F. Harkness, Davenport, 1935.
Dr. Thomas A. Burcham, Des Moines, 1936.

A silver vase, the gift of Dr. Jepson, was the centerpiece for the table at the luncheon. Bearing the inscription: "Past Presidents of the Iowa State Medical Society," it contains the names and years of service of eighty-seven presidents, beginning with Dr. Enos Lowe, who served in 1851, and ending with Dr. Prince E. Sawyer, Sioux City, who completed his term at the 1937 session. With space remaining for thirteen more names, a list of 100 past presidents may be recorded on the vase, which will be a souvenir for future reunions of these officers.

LOUISIANA

New Officers of Specialty Societies.—The Louisiana Society of Gastro-Enterology was organized at a meeting in New Orleans, May 5, with the following officers: Drs. Abraham L. Levin, president; Herbert L. Weinberger, vice president, and Louis Ochs Jr., secretary. —Dr. Edward L. King, New Orleans, was chosen president of the Louisiana State Gynecological Society at its recent annual meeting in Monroe. Dr. Armand G. McHenry, Monroe, was elected vice president, and Dr. Henry B. Alsobrook, New Orleans, secretary.

MAINE

Society News.—At a meeting of the Androscoggin County Medical Society, May 20, Dr. Augustus Riley, Boston, discussed "Pain in the Kidney Region." —Dr. Millard Carroll Webber discussed pneumonia before the Portland Medical Club, May 4. —The Kennebec County Medical Association was addressed in Togus, May 27, by Drs. Joseph E. Wheeler on "Fracture of the Patella: An Original Method of Surgical Repair"; Francis T. Williams, "Sarcoma of the Prostate"; Harry Levine, "Vitamins: Classification, Indications and Dosage," and Harry A. Goalwin, "The Less Common Causes of Headache."

MASSACHUSETTS

Society News.—Dr. W. Russell MacAusland, Boston, discussed recent advances in treatment of fractures before the Pentucket Association of Physicians, May 13, in Haverhill. —Dr. Albert H. Miller, Providence, R. I., discussed "Postoperative Pulmonary Complications" before the Boston Society of Anesthetists in Boston, May 4.

Dr. Magrath Resigns as Professor of Legal Medicine.—Announcement is made of the resignation of Dr. George B. Magrath, professor of legal medicine, Harvard University Medical School, Boston, effective September 1. Dr. Magrath was the first incumbent to fill this chair when it was created in 1932. In 1935 he resigned as medical examiner of Suffolk County, a position he had held since 1907. Dr. Magrath graduated from Harvard in 1898, becoming in that year assistant in pathology. In 1934 the George Burgess Magrath Library of Legal Medicine at the university was dedicated in his honor. Mrs. Francis Gleffner Lee, Littleton, N. H., provided the funds for both the professorship and the library.

MICHIGAN

Annual Upper Peninsula Meeting.—The fortieth annual meeting of the Upper Peninsula Medical Society will be held in Houghton, August 19-20. Speakers will include:

Dr. Herman L. Kretschmer, Chicago, Personal Experiences in the Treatment of Bladder Neck Obstructions by Means of Transurethral Electroresection (Review of 1,000 Cases).
Dr. David A. Cleveland, Milwaukee, Late Results of Intracranial Brain Trauma.
Dr. Michael L. Mason, Chicago, Management of Felon, Tenosynovitis and Acute Spreading Infection of the Hand.
Drs. John S. Lundy and Richard C. Adams, Rochester, Minn., Methods of Anesthesia and a Method of Blood Transfusion for the General Practitioner.
Dr. John D. Steele Jr., Ann Arbor, Treatment of Empyema.
Dr. Henry K. Ransom, Ann Arbor, Acute Surgical Lesions of the Abdomen.
Dr. Avery D. Prangen, Rochester, Early Treatment of Strabismus as Related to the General Practitioner.
Dr. Frank N. Wilson, Ann Arbor, Coronary Occlusion.
Dr. Howard K. Cummings, Ann Arbor, Importance of Examinations of the Cervix Uteri.
Dr. Geza de Takats, Chicago, Vascular Accidents of the Extremities.
Dr. Vernon L. Hart, Minneapolis, Orthopedic Surgery.

MISSISSIPPI

State Medical Election.—Dr. Joseph E. Green, Laurel, was chosen president-elect of the Mississippi State Medical Association at its annual meeting in Meridian, May 13, and Dr. William L. Little, Wesson, was installed as president. Dr. Thomas M. Dye, Clarksdale, was reelected secretary. The next annual session will be held at Jackson, May 10-12, 1938.

MISSOURI

New Officers of Special Societies.—Merl P. Moon, Ph.D., associate professor of bacteriology and preventive medicine, University of Missouri, Columbia, was chosen president-elect of the Missouri Public Health Association at its recent annual meeting in Springfield, April 29-30, and Dr. Edwin H. Schorer, Kansas City, was installed as president. Dr. John W. Williams, Jefferson City, is secretary. —Dr. Ralf Hanks, Fulton, was elected president of the Missouri Association for Mental Hygiene at its meeting in Fulton, May 2.

Personal.—Dr. Max A. Goldstein, founder and director of the Central Institute for the Deaf, St. Louis, received the honorary degree of doctor of laws from Washington University at its commencement, June 8. The institute is affiliated with the university. —Dr. Henry W. Schulz, St. Louis, was feted by the staff of the Lutheran Hospital, June 9, in recognition of his forty-eight years as a member of the staff. —Dr. Karl E. Maneval, Mexico, has been appointed health officer of Audrain County, succeeding the late Dr. Robert W. Berrey.

Flood Rehabilitation Project.—A program to rehabilitate the ten flood stricken counties in southeast Missouri was to have begun early in May, newspapers reported. Four district health units were set up to administer the program in the ten counties, the personnel in each unit including a health officer, sanitary engineer and two nurses, and sanitary inspectors. Dr. John Ben Jones, Charleston, is the health officer in district 1, covering Scott and Mississippi counties, with headquarters in Charleston. Health officers in other units are:

Dr. Theodore L. Waddle, Holden, district 2, Stoddard and New Madrid counties, headquarters in Dexter.
Dr. Asa Barnes, Kennett, district 3, Pemiscot and Dunklin counties, headquarters in Kennett.
Dr. Lynn M. Garner, Poplar Bluff, district 4, Butler and Ripley counties, to be expanded to include Carter and Wayne counties, headquarters in Poplar Bluff.

NEW HAMPSHIRE

Personal.—Dr. Zatae Longsdorf Straw, Manchester, received the honorary degree of doctor of science from Dickinson College, Carlisle, Pa., at the annual commencement. Dr. Straw is said to have been the first woman graduate of the college fifty years ago. She graduated from the Woman's Medical College of Pennsylvania, Philadelphia, in 1890 and spent some time in a government hospital for Indians in Idaho before going to live in Manchester. She has served in the state legislature.

NEW JERSEY

Personal.—John H. Northrop, Ph.D., of the Rockefeller Institute for Medical Research, Princeton branch, received the honorary degree of doctor of science at the annual commencement of Columbia University, June 1.

Tuberculin Testing in the Schools.—The testing of high school students in Jersey City to detect tuberculosis was begun, April 21, by Dr. Berthold S. Pollak, director of the Hudson County Tuberculosis Hospital, Secaucus, and his associates,

Drs. Immanuel Pyle, Abraham E. Jaffin and Leonard B. Fauquier, Jersey City. The physicians work in groups of six, with the assistance of eight nurses. Following the inoculation, students showing a positive reaction were to be x-rayed.

NEW YORK

Personal.—Dr. Joe R. Clemmons, assistant director of Strong Memorial Hospital, Rochester, has been appointed director of Roosevelt Hospital, New York. Dr. Clemmons, a graduate of the University of Tennessee School of Medicine, Memphis, in 1924, has been in Rochester since 1930. —Dr. Claude W. Munger, who recently resigned as superintendent of Grasslands Hospital, Valhalla, was honored at a farewell dinner at the Westchester Country Club, May 11, by various official groups with which he has been associated. Dr. Munger has been appointed director of St. Luke's Hospital in New York City. —Dr. James M. Blake, assistant superintendent of Glenridge Sanatorium, Schenectady, has been made superintendent to succeed Dr. James C. Walsh, who recently went to the Nassau County Sanatorium, Farmingdale. —Dr. Fraser D. Mooney, medical superintendent of Buffalo General Hospital, was elected president of the Hospital Association of New York State at the annual meeting in New York, May 21. —Dr. Frank F. Williams recently celebrated his fiftieth anniversary as health officer of the town of Canton. —Dr. Arthur J. Bedell, Albany, will sail June 30 for England to address the Oxford Ophthalmological Congress in July.

New York City

Society News.—At the last meeting for the season of the Medical Society of the County of New York, May 17, the speakers were Drs. Aaron Brown, on "Skin Manifestations of Allergy"; Albert Vander Veer, "Treatment of Hay Fever"; Robert Chobot and Robert A. Cooke, "Treatment of Asthma," and Maximilian A. Ramirez, "Internist vs. Allergist." —Dr. John R. Carty addressed the New York Roentgen Society, May 17, on "Roentgen Ray Therapy as a Diagnostic Measure in Tumors of the Mediastinum and Superior Sulcus."

Dr. Ballard Named Dean of College of Pharmacy.—Charles W. Ballard, Ph.D., professor of materia medica, Columbia University College of Pharmacy, has been appointed dean of the school, succeeding Henry V. Arny, Ph.D., whose retirement becomes effective July 1. Dr. Ballard received his degrees in pharmacy and philosophy at Columbia, where he has been teaching since 1907. He has been micro-analyst of the New York City Department of Health since 1917 and an associate member of the revision committee of the U. S. Pharmacopeia since 1920.

Personal.—Dr. George Gray Ward, emeritus professor of obstetrics and gynecology, Cornell University Medical College, and chief surgeon of the Woman's Hospital, will be made an honorary fellow of the British College of Obstetricians and Gynecologists, October 22, in London. Other Americans who received this honor were the late Drs. John Whitridge Williams, Baltimore, and William P. Graves, Boston. —The Harlem Eye and Ear Hospital gave a dinner, June 3, for Dr. Charles Bramman Meding in honor of his completion of fifty years of medical practice and as a trustee of the hospital. Dr. Meding graduated from Columbia University College of Physicians and Surgeons in 1887. —Dr. Raphael A. Bendove, assistant clinical professor of medicine, Long Island College of Medicine, Brooklyn, has been appointed assistant professor of clinical medicine at the New York Post-Graduate Medical School. —Dr. Clement B. Masson has been promoted to be assistant professor of neurologic surgery at Columbia University College of Physicians and Surgeons. —Dr. Stephen E. Manheimer, recently at Mount Sinai Hospital, has been appointed executive director of the Jewish Hospital of Brooklyn, succeeding Dr. Morris Hinenburg.

NORTH CAROLINA

Commission to Study Establishment of Medical School.—Gov. Clyde R. Hoey has appointed a commission authorized by the recent legislature to study the advisability of establishing another four year medical school in the state. Members of the commission are Drs. William M. Coppridge, Durham; William de B. MacNider, Chapel Hill, dean, University of North Carolina School of Medicine; Coy C. Carpenter, Wake Forest, dean of Wake Forest College School of Medical Sciences; Thomas W. M. Long, Roanoke Rapids, secretary of the Medical Society of North Carolina; Benjamin J. Lawrence, Raleigh, secretary of the state board of medical examiners; Judge L. R. Varner, Lumberton, and Joe W. Garrett, Madison. The commission will submit a report to the 1939 general assembly.

NORTH DAKOTA

Meeting of Specialty Society.—Dr. Henry P. Rosenberger, Bismarck, was elected president of the North Dakota Academy of Ophthalmology and Otolaryngology at the annual meeting in Grand Forks during the annual session of the North Dakota State Medical Association in May. Dr. Nelson A. Miles Youngs, Grand Forks, was made vice president and Dr. Frederick L. Wicks, Valley City, secretary. Dr. Arthur E. Smith, Los Angeles, was the guest speaker, on "Reconstructive and Plastic Oral Surgery."

OHIO

Society News.—The Academy of Medicine of Cincinnati was addressed, May 18, by Drs. Joseph B. Biederman on "Prevention of Constitutional Reactions in the Treatment of Allergic Patients" and Eslie Asbury, "Newer Methods in the Treatment of Fracture of the Hip." Dr. Otto J. Seibert presented a case report on "Multiple Annular Carcinomata of the Large Bowel."

Veteran Practitioners Honored.—Drs. P. Calvin Hartford, East Palestine, and Wilbert A. Hobbs, East Liverpool, who have practiced medicine for more than fifty years, were guests of honor at the annual outing of the Columbiana County Medical Society at the East Palestine country club, June 3. Dr. Harry Bookwalter, Columbiana, was toastmaster at the dinner, which followed a golf tournament. —Dr. Henry LuSern Hinkley has completed fifty years of practice in Green Springs; he was the first health officer of Seneca County, holding the position six years.

Plaque in Memory of Dr. Perkins.—A bronze plaque has been placed in the reading room of the department of hygiene and bacteriology of Western Reserve University School of Medicine in memory of the late Dr. Roger G. Perkins, who was professor of hygiene and preventive medicine at the school from 1910 to 1930 and professor emeritus from 1930 to 1936. He had been associated with the school since 1901. Dr. Perkins, who died March 28, 1936, also served, among other positions, as chief of the bureau of laboratories of the Cleveland division of health, city bacteriologist, consultant to the commissioner of health and director of the laboratories and chairman of the Cleveland Health Council.

OKLAHOMA

Society News.—Dr. Bert E. Mulvey, Oklahoma City, addressed the Garfield County Medical Society, Enid, May 27, on "Cardiac Arrhythmias" and Dr. Bert F. Keltz, Oklahoma City, "Use of Protamine Insulin." —Dr. Albert L. Salomon, Oklahoma City, was elected president of the Oklahoma Pediatric Society at the annual meeting during the session of the Oklahoma State Medical Association, which was held in Tulsa in May. Dr. Ben H. Nicholson, Oklahoma City, was elected secretary of the society.

PENNSYLVANIA

Society News.—At a meeting of the McKeesport Academy of Medicine, May 24, Charles G. King, Ph.D., professor of chemistry, University of Pittsburgh, Pittsburgh, discussed "Recent Advances in the Science of Nutrition." —A symposium on the prevention and control of scarlet fever was presented before the Montgomery County Medical Society in Norristown, June 16, by Drs. Stuart Mudd, Philadelphia; Max Strumia, Bryn Mawr; Percival Nicholson, Ardmore, and Pascal F. Lucchesi, Philadelphia. —Dr. George P. Müller, Philadelphia, discussed "Surgical Diagnosis" before the Delaware County Medical Society at its meeting in Chester, June 17. —At a meeting of the Fayette County Medical Society in Uniontown, June 13, Dr. Leo H. Crip, Pittsburgh, discussed "The Role of Allergy in the Practice of Medicine."

Philadelphia

Professor of Otology Appointed.—Dr. Horace James Williams has been appointed professor of otology at Jefferson Medical College to succeed the late Dr. Joseph Clarence Keeler. Dr. Williams graduated from Jefferson in 1912 and has been practicing in Philadelphia since 1917. For several years he has been associate in otorhinology at the Graduate School of Medicine of the University of Pennsylvania. He is director of service, department of otolaryngology, at the Germantown Dispensary and Hospital, and on the consulting staff of the Philadelphia Hospital for Contagious Diseases and Memorial Hospital.

Pittsburgh

Medical Bureau Established.—The Medical Bureau of Pittsburgh, sponsored by the Allegheny County Medical Society and the Odontological Society of Western Pennsylvania, opened June 1 at 1513 Clark Building, Seventh Street and Liberty Avenue. The bureau will be operated on a nonprofit basis and as soon as a sufficient cash surplus is accumulated the facilities will be expanded to provide more services, according to the *Pittsburgh Medical Bulletin*.

Prizes for Intern Case Reports.—The first prize in the twentieth annual case report contest of the Allegheny County Medical Society went to Dr. John B. Wood, Mercy Hospital, for his report of an unusual cause of portal thrombosis in a case reported in the service of Dr. John W. Fredette. Second prize was awarded to Dr. Gertrude E. Martin, Columbia Hospital, Wilkensburg, who reported a case in the service of Dr. William B. Hetzel of noma in a man aged 52 years following acute vegetative endocarditis. Dr. Wood graduated from the University of Michigan School of Medicine, Ann Arbor, in 1936, and Dr. Martin, Woman's Medical College of Pennsylvania, Philadelphia, 1936.

SOUTH DAKOTA

State Medical Election.—Dr. John F. D. Cook, Langford, was chosen president-elect of the South Dakota State Medical Association at its annual meeting in Rapid City, May 24-26. Dr. Earle A. Pittenger, Aberdeen, was installed as president and Dr. Clarence E. Sherwood, Madison, was elected secretary to succeed Dr. Cook, who has served several years in that office. The 1937 session will be held in Huron.

TENNESSEE

Upper Cumberland Annual Meeting.—The Upper Cumberland Medical Society held its forty-third annual meeting at Cookeville, June 24-25. Among the speakers were:

- Dr. Owsley Grant, Louisville, Ky., Report of Recent Series of Prostatic Cases Operated on by Various Methods.
- Dr. Franklin Jelsma, Louisville, Common Surgical Lesions of the Brain and Spinal Cord.
- Dr. John B. Youmans, Nashville, Some Aspects of Postgraduate Training.
- Dr. Henry L. Douglass, Nashville, Urology for the General Practitioner.
- Dr. Rettig Arnold Griswold, Louisville, Fractures of the Humerus.

WASHINGTON

Plague Infection Appears in Washington.—According to *Public Health Reports*, plague infection has been proved, by animal inoculation and cultural reactions, in fleas and lice taken from ground squirrels in Adams County. This is believed to be the first positive evidence that plague exists among wild rodents in Washington. The locality in which the infected fleas and lice were collected is the most northern point in the United States in which wild-rodent plague has been found, it was stated.

HAWAII

Annual Territorial Meeting.—Dr. Thomas Keay, Pepeekeo, was chosen president of the Hawaii Territorial Medical Association at its annual meeting in Hilo recently, and Dr. Douglas B. Bell, Honolulu, was reelected secretary. The next annual meeting will be in Honolulu. The program was presented by:

- Dr. Frederick K. Lam, Honolulu, Maternal and Child Program in Hawaii Under the Social Security Act.
- Dr. Carl W. Tempel, medical corps, U. S. Army, Biliary Giardiasis.
- Dr. Howard E. Crawford, Hilo, Trachoma in Hawaii.
- Dr. Gideon M. Van Poole, Honolulu, A Case of Papilloma of the Larynx in a Child.
- Dr. Carl J. W. Wilen, Hilo, Tuberculosis of the Trachea and Main Bronchi.
- Dr. Richard T. Treadwell, Kohala, A Rural Birth Control Program.
- Dr. Adolph G. C. Schnack, Honolulu, Roentgen Kymography of the Heart.
- Joseph E. Alicata, Ph.D., Honolulu, A Study of Trichinosis and Infectious Jaundice in the Hawaiian Islands.
- Drs. James S. Shinn and Nils P. Larsen, Honolulu, Hookworm Infestation in Hawaii.
- Dr. Fred L. Adair, Chicago, Obstetric Hemorrhage.
- Dr. Albert J. Desautels, medical corps, U. S. Navy, Present Status of Urology in the Navy.
- Dr. Arthur W. Duryea, Honolulu, Meningococcus Epidemics in Honolulu, 1929 and 1930.
- Dr. Guy C. Milnor, Honolulu, Obstetrics in Hawaii.
- Dr. Albert R. Behnke Jr., Pearl Harbor, medical corps, U. S. Navy, Anesthesia.
- Dr. Clifford G. Grulec, Evanston, Ill., Anemias of the New-Born.
- Dr. Lyle G. Phillips, Honolulu, gave his presidential address at a general session Friday evening.

GENERAL

American Documentation Institute.—The American Documentation Institute has recently been incorporated to develop and operate facilities that are expected to promote research and knowledge in various intellectual fields. The primary objective of the new organization will be to develop and apply the new technic of photomicrography to library, scholarly, scientific and other material. The board of trustees elected consists of Robert C. Binkley, Ph.D., Western Reserve University, Cleveland; Solon J. Buck, Ph.D., Washington, D. C., director of publications, National Archives; Watson Davis, Washington, D. C., director, Science Service; James Thayer Gerould, Litt.D., librarian, Princeton University Library, Princeton, N. J., and Dr. Ludvig Hektoen, Chicago, chairman of the National Research Council.

Digest of Treatment.—Volume I, number 1, of *Digest of Treatment* has just appeared, with the date of July 1937. The periodical will contain digests of articles, dealing specifically with treatment, published in various periodicals. A board of editors has been established. Many of the articles in the current issue deal with newer developments related to insulin. A wide range of periodicals has been consulted, although all the publications digested are English. Whether or not an abstract or digest periodical of this character is needed in the field of medicine will, of course, be determined by the extent of its use. Digests in other fields have apparently depended for their success on the choice of material and on the quality of the digest. This publication proposes to make its success wholly on an editorial basis, since advertising will not be carried.

Association of Obstetricians, Gynecologists and Abdominal Surgeons.—The annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at the Homestead, Hot Springs, Va., September 20-22. Among speakers listed on the preliminary program are:

- Dr. William Wayne Babcock, Philadelphia, Improvements in the Operative Treatment of Carcinoma of the Large Bowel.
- Dr. Cameron Duncan, Brooklyn, Treatment of Vesicovaginal Fistula.
- Drs. James R. Goodall and Richard M. H. Power, Montreal, Visceral Allergy.
- Dr. Jean P. Pratt, Detroit, Early Diagnosis of Carcinoma of the Fundus.
- Dr. Frederick S. Wetherell, Syracuse, N. Y., Diverticulitis of the Lower Colon in Women—Differential Diagnosis and Treatment.
- Dr. Walter T. Dannreuther, New York, Frank-Geist Operation for Congenital Absence of the Vagina.
- Dr. Daniel Dougal, Manchester, England, will deliver the Joseph Price Memorial Oration, on "The Problem of Endometriosis."

Changes in Status of Licensure.—The Kansas State Board of Medical Registration and Examination reports the following action:

- Dr. John W. Yankey, Mankato, license revoked, April 15, for conviction of a felony.
- The Kentucky State Board of Health recently reported the following actions taken at its January meeting:
- Dr. William Hammond Ashby, Oakland, license revoked.
- Dr. Eugene Fogle Beard, Somerset, license revoked.
- Dr. James W. Griffin, Lewisport, license restored; it was revoked Jan. 20, 1936.

The Massachusetts Board of Registration in Medicine reports the following:

- Dr. Arthur E. Brides, Stoughton, license restored April 20.
- Dr. William Martin Walsh, Boston, license revoked April 1 for gross professional misconduct.
- Dr. Hans William Bencker, Jamaica Plain, license revoked April 1 for gross professional misconduct.

The Illinois State Department of Registration in Medicine reports the following:

- Dr. Abraham Benjamin, New York, license revoked May 8 because of his conviction of attempted grand larceny in New York.
- Dr. Milton M. Glascoe, Jacksonville, Ill., license restored April 14.

Medical Bills in Congress.—*Changes in Status:* H. R. 6906 has passed the House, proposing to regulate the use of cannabis. This bill, among other things, proposes an excise tax of \$1 a year on physicians, dentists, veterinary surgeons and other practitioners who distribute, dispense, give away, administer or prescribe cannabis to patients on whom they, in the course of professional practice, are in attendance. Such practitioners are to be required to keep a record of all cannabis dispensed to a patient, showing the amount transferred and the name and address of the patient. This record must be kept for a period of two years. S. 2113 has been reported to the Senate, proposing to provide benefits on account of disability or death due to service in the armed forces of the United States in the event of war. *Bills Introduced:* S. 2572, introduced by Senator Pope, Idaho, proposes to amend the Social Security Act so as to increase grants to states for aid to dependent children by providing for payment to the state of an amount equal to one half instead of one third of the sums

expended by the state during each quarter. H. R. 7580, introduced by Representative Pace, Georgia, proposes that, in the administration of the laws and regulations providing for pension and compensation to veterans of the World War, any veteran disabled or deceased prior to Jan. 1, 1925, from lymphatic leukemia or pernicious anemia shall be presumed to have acquired his disability during the World War or to have suffered an aggravation of a preexisting lymphatic leukemia or pernicious anemia during such period.

Bequests and Donations.—The following bequests and donations have recently been announced:

Lancaster General Hospital, Lancaster, Pa., received half the \$55,000 estate of Alfred B. Grubb and will receive the other half after the termination of a trust.

Lankenau Hospital, Philadelphia, \$5,000 by the will of Mrs. Emma V. Arthur.

Presbyterian Hospital, Philadelphia, \$15,000 by the will of George A. Walker.

Pennsylvania Hospital, Philadelphia, \$21,000 by the will of the late Emily Dawson.

New York Eye and Ear Infirmary, Presbyterian Hospital and Roosevelt Hospital, all of New York, \$10,000 each by the will of the late Samuel Hopkins.

New Haven and Grace hospitals, New Haven, Conn., \$1,000 each, and Hospital of St. Raphael, New Haven, \$2,000 by the will of Noyes D. Clark, New Haven.

Methodist Episcopal Hospital, Philadelphia, \$20,000 to endow a free room for Methodist ministers; Misericordia Hospital, Philadelphia, \$5,000 by the will of Mrs. Sarah B. Field.

Meeting of Urologists.—The thirty-fourth annual meeting of the American Urological Association will be held at the Radisson Hotel, Minneapolis, June 28-July 1. The program will include symposiums on hydronephrosis, renal tumors and pyogenic prostatitis. The speakers at the general sessions will include:

Drs. Nelse F. Ockerblad and Hjalmar E. Carlson, Kansas City, Mo., The Distribution of Ureteral Pain as Determined by Faradic Stimulation in Man.

Drs. Carl F. Rusche and Samuel K. Bacon, Hollywood, Calif., Primary Ureteral Neoplasms, with Report of Two Cases and Review of the Literature.

Drs. J. Duane Miller and William J. Butler, Grand Rapids, Mich., Studies on Cystocele and Urinary Incontinence in the Female by Use of Cystograms and Urethrograms.

Drs. Richard Chute and Sylvester B. Kelley, Boston, Lesions of the Urinary Tract Producing the Symptoms of Intra-Abdominal Disease.

Drs. Walter G. Maddock and Reed M. Nesbit, Ann Arbor, Mich., Fundamentals in Water Balance.

Drs. Ira R. Sisk, John B. Wear and Andrew J. Trinkle, Madison, Wis., Peritoneal Lavage in Cases of Elevated Nonprotein Nitrogen of the Blood.

Drs. Norris J. Heckel and Willard O. Thompson, Chicago, The Influence of the Anterior Pituitary-like Hormone on the External Genitalia of Young Boys.

Drs. Charles B. Huggins and William J. Noonan, Chicago, Observations on Spermatocoele.

Drs. Grayson L. Carroll, Bransford Lewis and Louis C. Kappel, St. Louis, Further Clinical and Laboratory Observations of Mandelic Acid.

Dr. Gilbert J. Thomas, Minneapolis, will deliver his presidential address Wednesday on "The Treatment of Renal Tuberculosis" and Dr. William F. Braasch, Rochester, Minn., the Ramón Guiteras Lecture on "Clinical Data with Chronic Pyelonephritis."

Conferences on Health Education.—The National Committee on Mental Hygiene and local mental hygiene societies recently cooperated in holding conferences on education and mental health in Wilmington, Del., Philadelphia and Detroit, in an effort to promote closer understanding between educators and psychiatric leaders and more constructive measures on behalf of mental health in elementary schools. "Michigan's Mental Health—A Challenge to Medicine" was the theme of a medical session during the Detroit conference. Speakers included:

Dr. Robert H. Haskell, medical superintendent, Wayne County Training School, Northville, Mich., chairman.

Dr. James S. Plant, director, Essex County Juvenile Clinic, Newark, N. J.

Dr. Raymond W. Waggoner, director of the State Psychopathic Hospital, Ann Arbor.

Dr. Martin H. Hoffmann, Dearborn, director, parole clinic, Eloise Hospital, Eloise.

Dr. William H. Marshall, Flint.

Dr. Raymond B. Allen, dean, Wayne University College of Medicine, Detroit.

Drs. John C. Montgomery and Hugo A. Freund, both of Detroit.

Other speakers who participated in the various sessions included Drs. Clarence M. Hincks, New York, director of the national committee; Earl D. Bond, medical director, Mental Hygiene Institute, Pennsylvania Hospital, Philadelphia; Ira S. Wile, New York; Frederick H. Allen, director, Philadelphia Child Guidance Clinic; Camilla M. Anderson, Philadelphia, secretary, Pennsylvania Mental Hygiene Committee of the Public Charities Association; Bruce B. Robinson, director of the department of child guidance, Newark, N. J.; Messop A. Tarumian, superintendent of the Delaware State Hospital, Farnhurst, and George S. Stevenson, New York, National Committee for Mental Hygiene.

FOREIGN

Memorial to Crawford Long Unveiled.—A bronze plaque was recently unveiled as a memorial to Crawford W. Long in the library of the Royal College of Surgeons of Edinburgh. It was the gift of the Southern Society of Clinical Surgeons in the United States and bears the dates 1815-1878 and the inscription: "Discovered ether anesthesia at Jefferson, Georgia, March 30, 1842." Mr. Charles R. Nasmith, the American consul, unveiled the plaque, which was presented by the American society in appreciation of the reception accorded its members when they visited Edinburgh in June 1936.

Congress for Protection of Infancy.—The second International Congress for the Protection of Infancy will be held in Rome, October 4-8, following the fourth International Pediatric Congress, which will be September 24-30. There will be two sections of the congress, hygienic-sanitary and juridical-social, according to an announcement. Official languages will be English, French, German, Italian and Spanish. Members of the organizing committee are Drs. Giovanni B. Allaria, director of the pediatric institute of the Royal University of Turin; Nicola Pende, director of the institute of medical pathology, University of Rome; Francesco Valagussa, director of a preventorium in Rome, and Paolo Gaetano, attorney of the supreme court of Italy and vice president of the Italian union for child welfare. For information address Dr. Allaria, Corso Bramante 29, Torino 120.

Deaths in Other Countries

Sir Samuel Squire Sprigge, editor of the *Lancet* since 1908 and a member of its staff since 1892, died in London, June 17; he would have been 77 years old June 22. He received the degree of bachelor of medicine at Cambridge University in 1887 and the degree of doctor of medicine from the same university in 1904. He also studied at St. George's Hospital. He was a member of the Royal College of Surgeons of England and a fellow of the Royal College of Physicians. He accompanied Sir Walter Besant to Chicago in 1893 to attend a literary congress and after his return to England became assistant editor of the *Lancet*. In 1928 he visited the United States again to deliver the Hunterian Oration before the American College of Surgeons at its meeting in Boston in October. His subject was "Grand Curiosity." He served as chairman of the Society of Authors from 1910 to 1913. He was knighted in 1921. Sir Squire published in 1896 "The Life and Times of Thomas Wakley," the founder of the *Lancet*, and edited in 1901 "The Autobiography of Sir Walter Besant." He also edited "Conduct of Practice." Other publications included "Methods of Publishing," "Odd Issues," "An Industrious Chevalier," "Medicine, Its Practice and Public Relations," "Some Considerations of Medical Education," and "Physic and Fiction."

Government Services

Food Seizures in April

The U. S. Department of Agriculture reports the seizure of large shipments of sea foods during April. The greatest number of seizures was of fresh crabmeat contaminated during packing with filth and bacteria, with a total of 3,340 pounds confiscated in metropolitan areas of the Atlantic seaboard. Other canned fish seized because of decomposition were 810 cases of salmon and 550 of tuna. Parasitic worm infestation accounted for the seizure of 66,000 pounds of herring and 1,200 pounds of Canadian whitefish. There were 9,340 shipping cases of raisins seized because of contamination with hydrocyanic acid gas as a result of emergency fumigation during the maritime strike on the Pacific coast. There were 47,900 pounds of rice seized; it had been stored on ship in contact with containers of lead chromate, which sifted out and penetrated the sacks. Drug items seized during the month included 296 packages of absorbent cotton and 876 of gauze bandages, not sterile as labeled; 1,343 cans of impure anesthetic ether; 177 bottles of an isopropyl alcohol solution sold as rubbing alcohol unqualified; two consignments of glandular preparations which did not exhibit the physiologic activity claimed on the labels. The many fines imposed included one on the Goodwin Preserving Company, Louisville, \$330 and costs for short weight apple butter and preserves deficient in fruit, and \$350 and costs on the Davis Cleaver Produce Company, Inc., Quincy, Ill., for butter containing less than the legal minimum of butter fat.

LONDON

(From Our Regular Correspondent)

May 29, 1937.

Conference on the After-Care of the Tuberculous

The occasion of the coronation, which brought representatives from all parts of the British empire, was taken advantage of to organize a meeting of delegates to discuss the care and after-care of tuberculosis in the British empire. Sir Kingsley Wood, minister of health, said that until ten years ago tuberculosis stood foremost in England among diseases as a cause of death. In 1851-1855 it had a standardized death rate of 3,638 per million of population. Since then there had been a continuous decline, until in 1935 the rate was only 687. Nevertheless tuberculosis was in this country on the list of killing diseases next to cancer. At the end of 1935 there were in England and Wales 29,000 beds in institutions for the treatment of tuberculosis, and the country was covered with a network of tuberculosis dispensaries working in touch with physicians and health officers. The minister particularly commended village settlements for the tuberculous, where provision was made not only for treatment but for suitable occupation. Lord Horder, who presided over one of the sessions, said that, while there had been a considerable advance in the past two generations, the tendency to speak of tuberculosis as under control was an overstatement. In some parts of the empire the diagnosis of tuberculosis struck a death knell, as it formerly did in this country. The process of racial immunization was only beginning in those places.

THE BAD EFFECT OF CITY ENVIRONMENT

Dr. Sidney Vere Pearson spoke of the factors in city life which promoted tuberculosis. Big cities were sucking up the people from the rest of the country. The conditions that seemed to have a bearing on tuberculosis were (1) the time and energy wasted in traveling to and from work, (2) the growing difficulty of obtaining open-air recreation, and (3) the anxiety associated with city life in these days. Was it realized that London was 30 miles across? A town healthily planned might have a low tuberculosis and general death rate. The tuberculosis death rate for Letchworth garden city was only 38 per hundred thousand.

Dr. Frederick R. G. Heaf of the public health department, London County Council, said that the average incidence of tuberculosis for certain outdoor manual workers in London was greater than for indoor workers. He regarded this as a criticism of the idea that open air was essential to treatment. The actual cause of breakdown in tuberculosis was obscure; infection did not seem to be the chief item. The class that endured the hardest physical strain, received the lowest wages and spent the smallest amount on food was the one most prone to tuberculosis. Fatigue and undernourishment probably called for greater attention in a highly civilized and mechanized country.

ENVIRONMENTAL FACTORS IN CARE AND AFTER-CARE

Sir Pendrill Charles Varrier-Jones (the pioneer of the village settlement for the treatment of tuberculosis) thought that after-care was the most powerful method now available for the prevention of tuberculosis. The idea that only material environment need be considered was inadequate. Resistance was governed not only by material conditions but by the mental state, which might bring about imbalance of the endocrine system and so predispose to tuberculosis. In treatment the psychologic aspect, which was much neglected by physicians, must be considered. Enforced idleness led to destruction of moral fiber. But work of the right kind for the patient should be provided. It was disastrous to put him to what he regarded as an inferior job. After-care must be linked to hospital sana-

toriums. Too frequently the tuberculous were regarded as inferior—the medieval outlook. They were the victims of civilization. Society should try to compensate for the wrong it had done them by providing the best environment and restoring their working capacity.

INDIA

Major-General Sir Cuthbert Allan Sprawson said that the steady decline of tuberculosis in England had not occurred in the overseas countries and certainly not in India. Trustworthy figures were not available, but the public health commissioner recently estimated that there were about two million tuberculous persons in India. This was probably an underestimate, because many cases were undiagnosed and unreported. The death rate from pulmonary tuberculosis in Ipswich was 52 per hundred thousand, and in Chicago 56, but in Calcutta it was said to be 240 and was probably higher. Industrialization, especially if not controlled, and the free immigration of a rural population into cities were accompanied by an increase of tuberculosis, and this danger now existed in India and was an urgent problem.

CANADA

Dr. Robert E. Wodehouse said that Canada's attitude to the tuberculosis problem was greatly influenced by that of the United States. The death rate from tuberculosis in 1936 was about 60 per hundred thousand, about a third of what it was thirty years ago. Among the North American Indians the rate was high, about 700, while in other parts of the population it was as low as 25. In some areas there was ample free accommodation for any one with tuberculosis. While a man was in the hospital the state gave his wife the same pension as if she were a widow, and if she was the patient he received an allowance for a housekeeper.

Hospital Scheme for the Middle Man

While there are many charities for the sick poor, the large mass of workers with salaries from \$1,250 to \$2,500 have been passed over. Yet they are often not so well off, because of the claims on them, as many are of the so-called working class and cannot afford nursing fees. For some years the governors of St. Bartholomew's Hospital have realized the need for some provision for this class, but they are precluded by the terms of the hospital charter from applying any of its funds for this purpose. They are bringing forward a scheme for the erection of a special ward block adjoining the hospital, to be run as a financially separate entity but enjoying all the advantages and services which a large hospital offers, where persons of moderate means can be treated for a modest charge and where the services of the eminent physicians and surgeons of the hospital will be available. It is proposed to raise a capital sum of about \$600,000 for the erection and equipment of the building.

The Storage of Food

The Advisory Council of the Department of Scientific and Industrial Research has published an important report on research, carried out at the Low Temperature Station, Cambridge, on the storage of food. The effect of radiation from radioactive substances in destroying bacteria is being studied in connection with the storage of meat. Methods of storing eggs in different concentration of carbon dioxide are being tried. It has been found that a concentration of 60 per cent prevents attack on eggs by molds and gives an excellent yolk but an especially fluid white. Peas have been stored in refrigerated chambers with the atmosphere adjusted to the correct amount of carbon dioxide for long periods extending well into the summer. Their flavor, texture and appearance were entirely satisfactory. Excellent results under commercial conditions have been obtained by improved methods for the preservation of peas by freezing. Quick cooling and freezing following blanching in hot water were essential. The color and flavor of the peas were improved by the addition of from 0.1 to

0.15 per cent of sodium carbonate. The storage of flour is being studied. It has been found that during storage the bacteria content diminishes to a small value, while the fungous content rises to high values.

Samuel Kinnier Wilson

Neurology has sustained a great loss by the death of Dr. S. A. Kinnier Wilson at the age of 59. The son of an Irish clergyman, he was born in New Jersey, U. S. A., and educated at Edinburgh University. He was house physician to Sir Byrom Bramwell, a great teacher who turned his interest into neurologic channels. He settled in London, where he became physician and neurologist to King's College Hospital and physician to the National Hospital, Queen's Square. At the latter he came under the influence of Hughlings Jackson and imbibed from him a philosophic approach to neurologic problems. He is known all over the world for his discovery in 1911 of progressive lenticular degeneration, which is called "Wilson's disease." He showed that spasticity and tremor could be produced by a symmetrical lesion in the putamen and caudate nucleus. This was the beginning of knowledge of the motor functions of the basal ganglions. An accomplished writer and eloquent lecturer, he illuminated many neurologic subjects—aphasia and apraxia, disorders of motility and muscle tone, narcolepsy, hysteria and epilepsy. In 1920 he became editor of a new periodical, *The Journal of Neurology and Psychopathology*, which was later taken over by the British Medical Association. In 1928 he published "Modern Views on Neurology," in which he wove his own observations on many subjects into the fabric of neurology. But he did not live to publish what would probably have been his most important work, a textbook of neurology on which he had been engaged for ten years. He had written over three quarters of the text and he has left the remainder in unfinished form. It was expected that, with his gift of lucid exposition, he would have produced a standard international textbook like that of Gowers in the last generation. The hope remains that his colleagues will be able to complete the book so that a great loss to the medical world will not take place.

Opposition to Proposed Antivenereal Disease Law

The principal paragraphs of the bill now before the senate, which aims to prevent the spread of venereal diseases, were cited in a previous letter (*THE JOURNAL*, March 20). The question whether it would be possible to carry out some of the requirements of the proposed law was actively discussed at a recent medical meeting in Lyons. Dr. Charles Fouqué strongly objected to the paragraphs which make it obligatory for the attending physician to inform the public health authorities as soon as a patient consults him for a venereal disease and that the carrier of a venereal disease can be fined or imprisoned if he or she shall knowingly transmit it, and to the attempt to stop the present plan of medical inspection of licensed street walkers and houses of prostitution and substitute for it the closing of resorts of all types in which prostitution is carried on.

Dr. Fouqué maintained that such a plan would be ideal but that its authors were not realists and failed to see conditions as they actually exist. Those who wished to institute social reform measures ought to be realists and not idealists. No physician worthy of the name would feel obligated to reveal what he considered to be a professional secret. Syphilis is, after all, a disease which the carrier wishes to keep secret and does not wish to have known at either a hospital or a dispensary. The speaker believed that strict compliance with this compulsory notification feature of the law would defeat its object as a preventive measure of the spread of venereal dis-

eases. The patient who is financially able to consult a physician at his office will avoid doing so when knowing that the public health authorities must be informed of the nature of the ailment, and as a last resort the patient will be driven into the hands of quacks.

It will also be difficult, on account of the relatively long period of incubation of syphilis, to decide as to when the patient is in a state of being able to contaminate others. Nine times out of ten, neither the health official nor the judge will be able to determine who has been the carrier; hence the door is left open for many a case of blackmail of the suspected carrier. As to the measures for the suppression of prostitution, it will soon be found that these cannot be carried out. There are a certain number of women, the type as described by Lombroso, who will follow a life of prostitution, some for pecuniary gain, others not.

Fouqué endorsed the work of two of his colleagues, Carle and Lacassagne, who have accomplished excellent prophylactic work among the prostitutes of Lyons. Street soliciting can and ought to be suppressed. The Italian method of dealing with the question of prostitution was warmly endorsed. The houses are provided with all hygienic facilities to prevent contamination and are subjected to constant and strict medical and police surveillance. It would be desirable that these houses should be visited by women health inspectors, who should make every effort to bring it about that those who have been forced to live the life of prostitutes might be removed and given an opportunity to earn a livelihood elsewhere. Fouqué made a plea to the members of parliament not to pass a law that would soon be found to be inoperative.

Official to Direct Use of Leisure Time of Workers

One of the results of the forty-hour week law has been to give every worker one free day a week in addition to Sunday. For banks in larger cities, the free day is Saturday. In smaller communities the banks will close on Monday. All insurance companies are closed Saturdays and the same is true of factories. Grocery stores, butcher shops and bakeries will be closed on Monday. The large retail stores are attempting to solve the problem of whether to close all day Saturday or Monday. These details are cited to show how a law works out which gives two days a week leisure time to all workers, including even those employed on railroads. For the latter as well as for hotels and restaurants, the question of reducing the working week to forty hours is an especially difficult one.

How should the worker spend this extra day a week to the best advantage? The government, at the time the forty-hour week law was passed in 1935, created an assistant secretaryship of sports and leisure. The first occupant of this office is an energetic young man, Mr. Leo Lagrange, who has just announced his program in the April 18 issue of one of the Paris evening journals, the *Soir*. He stated that it was his ambition to do all in his power to encourage the creation of a strong, healthy and happy people by having them spend two days a week in the open air. A branch of the central bureau will be formed in each of the eighty-six departments of France to encourage the development of physical education. Mountain climbing and skiing enthusiasts will find shelters in every one of their favorite regions. A large park for all kinds of sports is being planned now, within an hour's ride from Paris, at Montlhéry. Similar recreation parks will be created within a radius of 30 miles from Paris in all of the metropolitan areas. The problem of building special paths for cyclists, as now exist in Belgium, will not be an easy one in France, where there are more than ten million people who prefer bicycle riding to any other form of outdoor exercise. Mr. Lagrange is also thinking of the season when inclement weather interferes with all outdoor sports except skating and skiing. He is planning to encourage workers to utilize their extra day of leisure (Saturday or Monday) to visit the museums or the cinemas and to

plan to take their annual vacations (with full pay) in winter instead of in summer. Special excursion rates will be arranged so that the worker will benefit by visiting other parts of France and also foreign countries. More than 500,000 persons engaged in skiing and other mountain sports during the past winter. The program to encourage the intellectual and physical condition of the workers is an ambitious one and it will be interesting to watch such a state-directed policy.

Application of Forty-Hour Week to Medical Laboratories

At the March 5 meeting of the organization of the Parisian region which looks after public relations of the medical profession, a protest was voted against the application of the forty-hour week law to the personnel of laboratories. The reasons given were that it was impossible, as in industry, to change those in charge of laboratory work at stated intervals. A medical technician who has commenced an analysis cannot always turn it over at a certain hour to another, but ought to follow it through to the end himself. The plea that the forty-hour week would decrease unemployment cannot apply to laboratories, because there are not more than 300 trained technicians in France, all of whom are employed. To close the laboratories all day, either on Saturdays or Mondays, as is now the case in industry, would be a hardship. Many examinations require continuous work for two or three days and it is often not practicable to suspend an analysis for two days (Saturday and Sunday or Sunday and Monday respectively) in succession. This new forty-hour week law as applied to industry, hospitals and laboratories has raised many a thorny problem for the employers.

Denatality Both a Moral and an Economic Problem

An intensive study of the question of natality in France has just been terminated and appears in the April 17 *Presse médicale*.

It was shown that there has been a decrease in the number of births as compared to the number of deaths here since the World War. The two classes that contribute almost entirely toward the maintenance of at least an equilibrium between the number of births and the number of deaths are certain of the middle classes and the poorer peasant class, the latter because they need help on their farms. The upper middle classes contribute less than any other toward an increase in the birth rate. The remedies that have been proposed are, first, to raise the moral standard of the younger generation by encouraging the "boy scout" movement and by making home life more attractive for girls; second, to create an economic environment which will favor natality, such as awards for large families, financial aid for young couples and abolition of taxes varying according to the number of dependents. At the March 7 meeting of the national assises under whose auspices this study of denatality was made, Dr. Sireday mentioned as causes the widespread use of contraceptives, abortion, sterility due to salpingitis, and the large number of women suffering from pulmonary tuberculosis. Speakers from various regions of France presented statistics. In the mountainous portions, the natality was 35 per thousand compared to 15 per thousand at lower altitudes. In the mining regions of northern France the natality had decreased from 35 to 18 per thousand. In Brittany, the annual number of births varies, having dropped during the past twenty years in one department (county) from 23,000 to 13,000, and in another the excess of births over deaths during the same interval has dropped from 3,300 to 150. In the majority of cases, this denatality was due to economic causes. In Normandy, denatality is especially marked, owing to the flocking of people from villages and small towns to the larger cities.

Mr. Risler, president of the commission on denatality, mentioned three important causes: (1) the rapidly increasing use

of alcoholic beverages; (2) syphilis, which causes 140,000 deaths a year, and (3) abortions, which are estimated to interrupt from 300,000 to 500,000 pregnancies annually.

Congress of French Alienists and Neurologists

The forty-first congress of French Alienists and Neurologists will be held June 30-July 5 at Nancy. Reports will be made on the following subjects: In psychiatry: Acute alcoholic delirium from the biologic point of view, by Dr. Bargues of Agen. In legal medicine: Neuropsychiatric examination of recruits, by Major B. Pommé of the Val-de-Grace Military Hospital of Paris. In neurology: Cerebellar atrophy by Dr. N. Peron of Paris.

BERLIN

(From Our Regular Correspondent)

May 20, 1937.

Congress of the Society of Internal Medicine

The German Society of Internal Medicine met at Wiesbaden during Eastertide with Professor Siebeck of Berlin presiding. The first main topic of discussion was nutrition. The opening report on "New Concepts of Nutrition" was read by Professor Bessau, ordinarius in pediatrics at Berlin. Among the causes of nursing mortality, deaths of premature infants no longer loom as large as formerly. The great body of fatalities occurring later in infancy are ascribable to defective nutrition. Every mistake in nutrition during the nursing stage gives rise to well known symptoms indicative of depleted vitality. The development of young children so affected remains arrested at an early infantile stage. If in the first half year of life a nutritional disturbance is present, a resultant pathologic syndrome will manifest itself in the second half year. The foregoing problems were discussed in detail with particular consideration of the vitamins. According to Bessau, bottle milk feeding is an immediate cause of hypovitaminosis, since the need of supplementary nutritive substances (above all vitamins B₁ and C) will be determined by the supply of nutritional elements of the first order. Among diseases based on vitamin deficiency belong cardiac dysfunctions in over fattened children and in status thymicolymphaticus. If defective nutrition leads to dysfunction of the mesenchyma, the latter condition may prove ultimately pathogenic for such diseases of age as cirrhoses, atherosclerosis and arthritis deformans. Many mesenchymoses of old age may be conditioned by constitutional factors, but the pathogenic rôle of the exogenous noxa has certainly been greatly exaggerated. Disturbances of nutrition should henceforth be studied and treated on a larger scale as a disease condition of fundamental importance.

Professor Bürger, policlinician of Bonn, next read a report on the nutritional treatment of diabetes in which he voiced his opposition to the so-called free diet advocated by Stolte for childhood diabetes. In insulin therapy one should take into account the glycogen which increases the blood sugar and which can even be obtained from dry insulin. In adults various aspects of treatment with insulin are to be considered. Not a maximal but an optimal amount of carbohydrate is required. The quantity will be determined by the state of metabolism and the amount of work performed. The favorable action of fruits and vegetables is apparently to be attributed to the supplementing substances; therefore more natural, unaltered carbohydrates should be supplied. In the discussion of Bürger's paper, the most varied opinions were expressed by both the pediatricians and the internists.

Among other papers submitted was that of Otfried Foerster of Breslau on the vegetative regulation of the hypothalamus. It is not always established with certainty that from the nuclei of the third ventricle fibers pass toward the hypophysis. It is certain, however, that the hormone of the posterior lobe passes into the third ventricle. That a diabetes insipidus appears after extirpation of the hypophysis cannot be verified, as

long as the tuber cinereum is unimpaired. If, however, the tuber cinereum is destroyed also, which happens in dogs, disturbances of growth will be manifested and later on obesity. If hypophysial damage has taken place, any of an extraordinary diversity of symptoms may appear, including hypertonia, hypersexuality and diabetes insipidus. Clinical observations have demonstrated that radical removal of the sella turcica will be followed by diabetes insipidus only if the floor of the third ventricle is damaged in the vicinity of the regio hypothalamica. The accompanying phenomena are psychic defects and hyperthermia.

The third day was given over to reports on the pathology of the thyroid. The first speaker, Eugster of Zurich, discussed the pathogenesis of endemic goiter with particular consideration of the question of heritability. Two large scale examinations were made of 15,000 persons from fourteen Swiss villages. A first series of examinations was carried out in 1912-1913 and a second twenty years later. With respect to heritability it was ascertained that susceptibility in older siblings is greater than among the younger; the latter are often spared because the mother has acquired a fully developed goiter after several pregnancies. Goitrous immigrants into goiter-free regions have goiter-free progeny, so in such instances the environmental influences preponderate. Research on twins yielded the following important observations: dizygotic twins who are goiter carriers are not affected in the same manner; enzygotic twins, however, virtually always exhibit completely (and even histologically) identical types of goiter. Accordingly it is considered proved that in the pathogenesis of goiter the capability of reaction against external influences is inherited. Climatic influences are expressed by the incidence of the manifestation in certain "goiter years." Even the "little climate" may be a factor: residence in a lower story results much more frequently in the production of goiter than residence in an upper story. Thus it was observed that in enzygotic twins, that is, twins representing identical hereditary factors, the twin who resided in a lower story became goitrous, whereas the other twin who lived upstairs did not. Distribution of goiter in various localities is chiefly domiciliary and not familial. Regarding the influences exerted by the soil, it can be said that regions abounding in water favor the development of goiter. Abundance of iodine may counteract the factors conducing to goiter within a particular region, but this does not mean that goiter zones must necessarily be deficient in iodine. The aggregate of observations lead one to conclude that the pathogenesis of endemic goiter is to be explained in terms of environmental influences on the phenotype as well as in heredity. That is to say, in addition to the inherited traits other factors must be considered such as topography, meteorological variations, the atmosphere of the dwelling, the type of community and the nature of the soil. These environmental factors tend to interfere with hereditary modifications and traits. The whole salt (iodized salt) prophylaxis has been used with favorable results. Wilhelm Falta of Vienna discussed the interrelation of exophthalmic goiter and the diencephalon. In that disease the thyroid center is observed to be in a state of heightened irritability. The increased thyroid activity depends in part on the state of stimulation in the diencephalon but there likewise exists a primary state of irritability in the regio subthalamica. However, this does not mean that all cases of exophthalmic goiter are conditioned by the central nervous system. Falta concluded on the basis of his investigations that the increase in thyroid function makes possible secondary alterations of the centrum: in addition to the peripheral point of attack the thyroxine possesses another point of attack in the diencephalon and this is especially the case in toxic influences. Conversely, there exists in the nervous disorders that involve the diencephalon high grade resistance to thyroxine. Other observations too speak for the central path. Because of the possibility

that the increased blood sugar content may be lowered in exophthalmic goiter by the use of barbituric acid derivatives, experiments have been attempted with a "twilight sleep" produced by these substances and a measure of success has been obtained. Many pathologic manifestations are thus abolished, such as tachycardia, perspiration and tremor. This provides ground for the assumption that by use of this method the thalamencephalic centrum in its increased state of irritability may be reduced. The level of iodine in the blood also was diminished by around 30 per cent. Against the concept of a pituitary type of exophthalmic goiter as a disease entity is the fact that in this disease the thyrotropic hormone in the blood is not increased. Neither is central exophthalmic goiter to be regarded as a distinct type. In concluding his report, Falta repeated his contention that the etiology of exophthalmic goiter is to be sought in a plurality of factors. His observations led him to believe that psychic trauma too may frequently influence the pathogenesis. This report was followed by an extensive discussion.

The fourth day of the congress was dedicated to the problems of tuberculosis. As the internists met in joint session with the German Tuberculosis Society, this day's proceedings are reported separately.

Tuberculosis Congress

The German Tuberculosis Society met during Eastertide at Wiesbaden in joint session with the German Society of Internal Medicine. The first principal topic was "Of What Importance is a General Tuberculous Infection to the Human Organism?" Speaking as a pathologist, Professor Huebschmann of Düsseldorf said that tuberculosis in any form is a general disease of the entire organism. Alterations of the myocardium, spleen and kidneys ought rather to be ascribed to the general debility of the tuberculous organism and are connected with the destruction of tissue which is so extensively manifested in tuberculosis. Whether or not certain independent disease entities such as rheumatism and many nervous disorders are in any way associated with the direct action of the bacillus of tuberculosis remains doubtful. In conclusion, Dr. G. v. d. Weth of Beelitz Sanatorium, speaking as a pathologist, said that the pathogenic importance of quiescent scars of a previously arrested tuberculosis should not be overestimated. Furthermore, there are the stationary tuberculous processes with bacillary excretions which, with respect to the individual, are hardly to be designated as disease, yet which for the environment and the nation represent foci of disease necessitating medical and prophylactic measures. Deist of Ueberruh discussed from a clinical point of view the manifold phenomena of tuberculosis in various organs. The importance of pleuritis exsudativa as the initial symptom of a previously unmanifested tuberculosis is certain, if another etiologic disorder, pneumonia or polyarthritis, for example, is not present. Many manifestations in various organs, as the blood vessels or the heart, in the gastro-enteric canal or in the liver, may be explained in terms of the hematogenic reciprocal toxic effect of the bacillus of tuberculosis. Cases of tuberculous rheumatism are to be similarly evaluated, but general incorporation of acute polyarthritis within the framework of tuberculosis can by no means be considered as certain. The question whether and to what extent the tuberculosis bacilli may (intact or merely functionally) pass through damaged organs without producing an organic tuberculosis is best studied in the kidneys. The bacillus of tuberculosis is able under certain conditions to pass through a kidney without producing any clinically tangible results. There can be no question that tuberculosis is capable of exerting direct influence on the course of recognized mental disorders, schizophrenia in particular.

The topic of discussion on the second day was specific chemotherapy in tuberculosis. Schlossberger of Berlin said that no significant observations with respect to tuberculosis in man

could be elicited from chemotherapeutic experimentation with animals. In the artificially infected experimental animals the disease follows a wholly disparate course from that which it takes in the human subject. In animals the antituberculosis defense forces of the organism seem to be virtually nonexistent. Accordingly, advances in the chemotherapeutic approach to tuberculosis can be achieved only by careful verification of the effect of seemingly suitable new substances on the human organism. The speaker is of the opinion that in treatment with gold the compound, in addition to its influence on the cells of the infected organism, also directly affects the bacilli of tuberculosis. Prof. Adolf Bacmeister of St. Blasien, speaking from the clinical point of view, said that at present the best founded theory was that of an action chiefly catalytic and nosotropic exercised by the gold compound on the reticulo-endothelial system. This effect is manifested clinically by a focal reaction and an activation of the general defense mechanisms. Thus this type of treatment serves at one and the same time as a stimulation therapy and as a treatment directed against the disease as such. It is indicated in all exudative and productive forms of tuberculosis, provided the organism's reticulo-endothelial system still possesses sufficient power of reaction. The use of newer improved preparations has reduced, if it has not yet abolished, the danger of a noxious influence of the gold. All other forms of chemotherapy, the speaker said, are of minor importance compared with the gold treatment.

SWITZERLAND

(From Our Regular Correspondent)

April 24, 1937.

The Use of Roentgen Therapy in Malignant Tumors

According to H. R. Schinz, professor of roentgenology at Zurich, in the *Münchener medizinische Wochenschrift*, in Switzerland, a country of 4,200,000 population, 5,696 persons died of cancer in the year 1930. In the canton of Zurich alone there were, during the same year, 1,913 cancer deaths in a population of 611,000 and in the city of Zurich 385 cancer deaths in a population of 245,000. One in every eight deaths occurring in Switzerland is due to cancer and the proportion for both the canton and the city of Zurich is one cancer death in every seven. Cancer has increased, he believes, as a result of the increased average age of the population. The curve of cancer mortality has passed the curves for infant mortality and fatal tuberculosis. In the city of Zurich, cancer is the most frequent cause of death; in the year 1934, for example, 17 per cent of all fatalities were due to cancer as against 9 per cent to tuberculosis and 15 per cent to arteriosclerosis. During the years 1926 to 1933 the upper respiratory and alimentary tracts (with the exception of the esophagus) were the fourth most frequent seat of cancer among males. If cancers of the esophagus had been included, these areas would have occupied second place.

In cancers of the upper respiratory and alimentary tracts the most important therapeutic procedure is irradiation. Three principal methods are available: treatment with roentgen rays, with radium and with telecurietherapy. Most patients coming to Zurich for treatment are in a stage when local roentgen therapy is no longer possible. Telecurietherapy cannot be carried out because of the scarcity of the element. Roentgen treatment is therefore administered in the form of a protracted-fractionated and prolonged irradiation. This treatment is rigorous, it may even give rise to exudative radio-epidermitis and fibrinous radio-epithelitis and these lesions may in turn require several weeks' treatment. During an earlier period (1919-1928) a primary, local and regional freedom from symptoms could be obtained in only 14 per cent of the cancer cases. From 1929 to 1935 this could be accomplished for 53 per cent of the cases. In the first period 319 patients were treated, in

the second 517. Formerly, improvement could be obtained in 31 per cent of the cases; now such results (shrinking or disappearance of the cancer) are obtained in 77 per cent. During the period from 1919 to 1928 the percentage of permanent results was small except for cases in which the seat of the disease was the oral cavity or the inner larynx. For the whole period, "cures" that lasted for three years could be obtained in only 6 per cent of the cases and for five years in 5 per cent. In cancer of the hypopharynx there were no cures lasting as long as three years. Lasting results were more frequent during the second period (1929-1935). In 22 per cent of all the cases in this period there had been no recurrence three years after cure and in 13 per cent there had been no recurrence five years after cure. Early recognition, early diagnosis and early treatment remain of paramount importance.

Chronic Nervous Disorders As a Cause of Death

Professor Isenschmid of Berne has recently published a critical discussion of chronic nervous disorders as a cause of death in Switzerland. The chief source of information was the official mortality statistics, which have for a long time been well compiled in Switzerland. According to the statistics the chronic nervous disorder responsible for the greatest number of deaths in Switzerland was epilepsy (1,260 deaths in the five year period from 1928 to 1932). This was followed by paralysis agitans (623 deaths), dementia paralytica (557 deaths), multiple sclerosis (446 deaths) and finally, but much less frequently, tabes dorsalis (211 deaths).

Mortality statistics provide a clearer picture of the relative incidence of various diseases than can be obtained from computations of living persons affected with the same disorders. Diseases that cause sudden death are likely to be underestimated statistically as opposed to chronic nervous disorders, if the sole basis of comparison is the number of contemporaneous living patients. The mentioned 1,260 fatal cases of epilepsy in a five year period is equivalent to 5.1 per thousand of the total number of deaths occurring within the same period. The corresponding proportions per thousand for other diseases are paralysis agitans 2.5, dementia paralytica 2.27, multiple sclerosis 1.8 and tabes 0.86. The two sexes are about equally represented among persons dying of paralysis agitans. Among patients who succumbed to epilepsy, men preponderated in a ratio of 6 to 5. Among those dying of the two metasyphilitic diseases there was an even greater preponderance of male patients; the ratios were 2 to 1 for tabes and approximately 12 to 5 for paralysis. Women were more frequently victims of multiple sclerosis in the ratio of 17 to 10. The high mortality of epileptic patients between the ages of 20 and 30 was striking; 21 per cent of deaths from epilepsy of men and 12 per cent of the deaths of women occurred during an attack. Attention was called to the low suicide rate in persons affected with chronic nervous disorders. Suicide accounted for only 1.65 per cent of the fatalities covered by the survey, whereas for all Switzerland in recent years about 2.4 per cent of the total deaths have been by suicide.

Exploration with the Gastroscope

At the medical clinic of Basel University, of which Prof. Rudolf Staehelin is director, data on the use of the gastroscope have been assembled and discussed by Dr. Kapp before the Basel Medical Society. Rigid gastroscopes of small caliber cause fewer injuries than those of larger caliber such as were formerly used. The former, however, can be of service in only about 85 per cent of the cases, since under no circumstances can the introduction of the instrument be forced because of the danger of lacerations. Flexible gastroscopes have the advantage that with reasonable care no injuries will be incurred. Their disadvantages are that if the curve exceeds 45 degrees the view will be obstructed, which will also occur if the lamp

is not bright or the window is smeared. The tubes, too, are considerably thicker. Gastroscoy is to be regarded as less indicated in carcinoma or ulcer, which diseases can be usually well diagnosed by other means, than in the various forms of gastritis.

Kapp has also devised an anoscope by means of which it is possible, when a section of the wall of the instrument is removed, to obtain a good view of the lowest intestinal region.

MOSCOW

(From Our Regular Correspondent)

May 25, 1937.

No Smallpox in the Soviet Union

Vaccination was not compulsory in tsarist Russia; every year more than 100,000 persons became infected with smallpox. During the World War and the civil war the number of patients reached thirty in each 10,000 persons. The Soviet government issued in 1919 and 1924 two decrees about compulsory vaccination. Smallpox then gradually diminished; 14,154 smallpox patients were registered throughout the country in 1927 and only 400 in 1936. There were no registered patients in the Soviet Union during January and February 1937. About 40,000,000 persons are vaccinated and revaccinated every year. In middle Asia in 1936 a special investigation was made to find whether any patients were hidden by the population, but no instances of such hiding were found. It is interesting to note that in India, during the period January to September 1936, 203,107 cases of smallpox were registered and in the United States 6,254 cases.

Prostitution in the Soviet Union

In 1913 there were 20,000 registered prostitutes in Moscow. In 1931 only 700 women engaged in prostitution were found in Moscow and in 1932 only 470. The Women's Curative Labor Prophylactorium of Moscow, an establishment for combating prostitution, in August 1936 showed the number of prostitutes to be about 100. The function of the prophylactorium is to help these women to return to normal life. In 1928, says Dr. Mark S. Danishevsky, director of the Moscow Prophylactorium, there were forty prophylactoriums in the Soviet Union. After 1931 four were closed in Moscow and twelve in other parts of the country. Now there are only six in the whole country, quite enough to take care of the few remaining homeless women.

The Soviet state combated prostitution under the slogan "Fight Prostitution, not the Prostitute." The campaign was begun in 1922, by the People's Commissariat of Health, Labor and Trade Union. It prevented prostitution by the following regulations: No enterprise could discharge women employees who were without means of substance, single girls without parents, pregnant women or women with children. Against existing prostitution, measures were taken such as (a) special supervision at railroad stations, hotels, workers' dormitories, ports and public bath houses, (b) several legal measures against all agents and agencies of prostitution, and (c) establishment of free dispensaries for treating venereal diseases.

In 1929 the government issued a decree to hasten the abolition of prostitution. It recommended the training of women for more highly qualified work in industry, encouraged the employment of women in all branches of production, called for intensification of antiprostitution propaganda, and demanded punishment of persons guilty of debauching young girls. In addition, the decree suggested establishing two farms near Moscow for reclaimed women requiring work on the land, explained how the work of the forty prophylactoriums of the country could become more effective, and outlined plans for founding an institute of labor education for prostitutes. With the aim of bringing former prostitutes back to useful socialist labor, the Women's Curative Labor Prophylactorium was established. It

was decided first that women must be quite free to enter without any semblance of force. The severest punishment allowed was expulsion. Thus no women entered the prophylactorium other than voluntarily. No funds from private sources were accepted for this purpose. All medical service care and attention to the patients and all medicines had to be free of charge, the state meeting all the costs. Finally a woman was required to remain at the prophylactorium for an average of two years and could be discharged only when the institution had found her a job and a room outside. In the rehabilitation of a street walker, after her disease has been cured in the main prophylactorium, she goes to the affiliate prophylactorium in another locality, where there are factories and shops for women who had worked before. The institutions continue to watch over their pupils for a given period. The Moscow Prophylactorium has sent out about 2,500 women. Thirty-two per cent have been several times rewarded for good work at their place of employment. Seventeen per cent are students in technical schools and institutes. Sixty-five per cent have married and 44 per cent are now mothers.

Expenditure on Public Health in 1937

According to the decision of the Central Executive Committee and the Council of People's Commissars of the Union of Socialist Soviet Republics issued March 29, 1937, concerning the national economic plan of the country for 1937, the total expenditure on public health is fixed at 7,528.1 million rubles, against 5,803.5 million rubles in 1936. Capital investments in public health will be equal to a billion rubles. About 574 million rubles of this sum will be spent on building maternity homes, nurseries and milk kitchens. The remainder will go to building new hospitals, research institutes, sanatoriums and medical schools. The total number of hospital beds in 1937 will be 619,800, as against 564,000 in 1936. At the beginning of the school year a number of medical institutes in Archangel, Gorky, Ijevsk, Ivanovo, Krasnodar and other towns will be greatly enlarged. There will be erected thirty new buildings and six clinics, as well as thirty-nine new schools for middle medical staffs. This year the building will be completed in Moscow of new houses for the Central Health Resort Institute and for the Disinfection Institute. Twenty-five million rubles will be spent for the building of the All Union Institute of Experimental Medicine. New buildings for the tropical institute, traumatologic institutes, Institute of Epidemiology and Microbiology, Institute of Oncology and Institute of Blood Transfusion will also be erected. The number of physicians at the end of the third five year plan will be 176,000, in comparison with 104,000 in the present year.

Marriages

CHARLES ALLEN EASLEY JR., Richmond, Va., to Miss Elizabeth Fitzgerald of Danville, in May.

H. PRESTON PALMER to Miss Helen Theresia Rosen, both of Scott City, Kan., Dec. 25, 1936.

JACOB J. KIRSHNER to Miss Estelle Mildred Varbalow, both of Philadelphia, February 21.

WILLIAM J. BUCK, Belle Glade, Fla., to Miss Sue Florence of Palm Beach, May 22.

JESUS M. QUINONES, Vieques, P. R., to Miss Santin Olmo of Barceloneta, June 3.

CARL A. KUNATH to Miss Rachel Dorothy McDaniel, both of Iowa City, June 5.

ROSCOE M. NEEDLES, Anita, Iowa, to Miss Ida Sabo of Canton, Ohio, May 20.

PAUL L. DEWAELE to Miss Geraldine E. Hartz, both of Detroit, May 5.

JAMES L. CHALKER to Miss Mary C. Fore, both of Ocala, Fla., April 14.

Deaths

Charles Sumner Benedict, New Rochelle, N. Y.; University of Vermont College of Medicine, Burlington, 1882; University of the City of New York Medical Department, 1883; member of the Medical Society of the State of New York; past president of the Westchester County Medical Society; formerly member of the city of New York board of health; aged 80; died, April 15, of carcinoma of the prostate and osteitis deformans.

Thomas Patton Cheesborough, Asheville, N. C.; University of the City of New York Medical Department, 1891; member of the Medical Society of the State of North Carolina; veteran of the Spanish-American and World wars; aged 67; died, April 3, of internal hemorrhage due to ruptured varicosities of the esophagus and cirrhosis of the liver.

Cyrus Fletcher Boyers, Morgantown, W. Va.; Barnes Medical College, St. Louis, 1896; member of the West Virginia State Medical Association; at various times city and county health officer, and member of the city council; aged 63; on the staff of the Monongalia County Hospital, where he died, April 14, of lobar pneumonia.

Frederick Lewis Blair, Providence, R. I.; University of Maryland School of Medicine, Baltimore, 1911; member of the Rhode Island Medical Society; veteran of the Spanish-American and World wars; formerly on the visiting staff of the Homeopathic Hospital; aged 59; died, April 24.

Charles B. Almond, Winder, Ga.; University of Georgia Medical Department, Augusta, 1891; member of the Medical Association of Georgia; for many years a member of the board of education and board of health; aged 66; died, April 16, in the Emory (Ga.) University Hospital.

Elwin H. Ashcraft, Coudersport, Pa.; College of Physicians and Surgeons, Baltimore, 1881; member of the Medical Society of the State of Pennsylvania; for many years a member of the state board of health, county coroner and medical inspector; aged 82; died, April 12.

John Ellis Ashcraft, Fayetteville, N. C.; University of the City of New York Medical Department, New York, 1887; member of the Medical Society of the State of North Carolina; formerly a member of the state board of health; aged 76; died, April 26, of heart disease.

Frank Alsworth Waples, Houston, Texas; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; fellow of the American College of Physicians; formerly on the visiting staff of the Southern Pacific Hospital; aged 69; died, March 4.

Francis Van Vechten Wethey Ⓢ Enfield, N. H.; University of Vermont College of Medicine, Burlington, 1924; served during the World War; aged 43; died, March 5, in the Mary Hitchcock Memorial Hospital, Hanover, of hypertensive heart disease.

Walter Sidney Swan, Harrisburg, Ill.; Jefferson Medical College of Philadelphia, 1877; member of the Illinois State Medical Society; for many years a member of the board of education; aged 82; died, March 28, of cardiorenal degeneration.

William Ashton Reese, Petersburg, Va.; Medical College of Virginia, Richmond, 1915; member of the Medical Society of Virginia; served during the World War; city physician; on the staff of the Petersburg Hospital; aged 47; died, March 21.

Wily Simeon Adams, Cherokee, Ala.; University of Georgia Medical Department, Augusta, 1908; member of the Medical Association of the State of Alabama; aged 52; died, April 1, in the South Highlands Infirmary, Birmingham.

James M. Williams, Malvern, Ark.; Memphis (Tenn.) Hospital Medical College, 1895; member of the Arkansas Medical Society; past president of the Hot Spring County Medical Society; aged 81; died, March 17, of pneumonia.

Thomas Jay Robeson, Bloomington, Ill.; Northwestern University Medical School, Chicago, 1893; member of the Illinois State Medical Society; veteran of the Spanish-American War; aged 74; died, March 26.

Anna Marie Mosgrove, San Francisco; Cooper Medical College, San Francisco, 1899; member of the Associated Anesthetists of the United States and Canada; aged 85; died, March 26, of coronary occlusion.

Gibson Reynolds, Montgomery, Ala.; Columbia University College of Physicians and Surgeons, New York, 1901; member of the Medical Association of the State of Alabama; aged 60; died, March 13, of heart disease.

Elmer Clinton Bruch, Bethlehem, Pa.; Baltimore Medical College, 1891; Jefferson Medical College of Philadelphia, 1892; aged 67; for many years on the staff of St. Luke's Hospital, where he died, April 16.

Robert Bethune Warren, Deatsville, Ala.; Medical Department of the University of Alabama, Mobile, 1903; aged 64; died, March 17, in the Fitts Hill Hospital, Montgomery, of coronary occlusion.

J. Henry Wishard, Leitersburg, Md.; Jefferson Medical College of Philadelphia, 1883; aged 80; died, March 27, in the Waynesboro (Pa.) Hospital, of cerebral hemorrhage and bronchopneumonia.

Jacob C. Solomon Ⓢ Los Angeles; American Medical College, St. Louis, 1893; formerly professor of ear, nose and throat, California Eclectic Medical College; aged 72; died, March 15, of arteriosclerosis.

Henry J. Wolf, New York; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1884; on the staff of the Lebanon Hospital; aged 75; died, March 22, in the Lenox Hill Hospital.

John Marquiss Blair, Houston, Texas; Rush Medical College, Chicago, 1884; formerly medical director and owner of a sanatorium bearing his name; aged 78; died, April 2, in a local hospital.

Harriet Josephine Cossmann, Stapleton, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1929; aged 33; died, April 24, in Asheville, N. C., of pulmonary tuberculosis.

Joseph H. Schnurrenberger, Austintown, Ohio; Western Reserve University Medical Department, Cleveland, 1892; for many years a member of the school board; aged 71; died, March 26.

Joseph Henry Akers, Attleboro, Mass.; Dartmouth Medical School, Hanover, N. H., 1884; member of the Rhode Island Medical Society; aged 80; died, April 4, in the Sturdy Memorial Hospital.

Edward Howard, San Diego, Calif.; Harvard University Medical School, Boston, 1887; aged 82; died, March 19 in Santee, of bronchopneumonia, cerebral hemorrhage and arteriosclerosis.

Elizabeth Mattson Clark, New Brunswick, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1893; aged 91; died, April 4, of myocarditis and auricular fibrillation.

James Josiah Martin, Long Beach, Calif.; Eclectic Medical Institute, Cincinnati, 1898; member of the California Medical Association; aged 71; died, March 21, of cerebral embolism.

Frederick Henry Charles, Cumberland, Md.; University of Maryland School of Medicine, Baltimore, 1886; aged 75; died, March 19, of arterial hypertension and myocarditis.

Timothy Joseph Sullivan, Newton, Mass.; Harvard University Medical School, Boston, 1902; aged 69; died, March 28, of chronic myocarditis and arteriosclerosis.

Ruel Bidwell Karibe, New York; University of Pennsylvania Department of Medicine, Philadelphia, 1892; served during the World War; aged 66; died, March 30.

Alfred Montreuil, Prince Albert, Sask., Canada; M.B., Laval University Faculty of Medicine, Quebec, Que., 1908, and M.D., 1910; aged 51; died, March 1.

William Otto Winter Ⓢ St. Louis; Marion-Sims College of Medicine, St. Louis, 1897; aged 67; died, March 31, in the Lutheran Hospital, of heart disease.

Selwyn Kent Smith, Belize, Honduras, Central America; University of Western Ontario Medical School, London, 1924; aged 37; died, March 7.

William James Hanford, Los Angeles; New York Homeopathic Medical College, 1883; aged 78; died, March 8, of arteriosclerosis.

Clarence Simon Atwood, Deming, N. M.; University of Buffalo School of Medicine, 1935; aged 32; died, April 28, of pneumonia.

Louis A. Bowling, Charleston, W. Va.; Kentucky School of Medicine, Louisville, 1897; aged 76; died, April 17, of pneumonia.

Joseph Vincent Power, Spencer, Tenn.; St. Louis College of Physicians and Surgeons, 1909; aged 64; died, March 8.

Friede Feige Van Dalsem, Huron, S. D. (licensed in South Dakota in 1887); aged 92; died, March 6, of senility.

Francis George Wallbridge, Belleville, Ont., Canada; Trinity Medical College, Toronto, 1892; died, March 4.

FACTORS IN LACK OF COAGULATION IN HEMOPHILIA

To the Editor:—In the May 15 issue of THE JOURNAL there appeared an editorial on the antihemorrhagic factor in foods, in which the following statements were made: "In hemophilia the deficient functioning of the thrombocytes was pointed out earlier by Howell and Cekada, supplementing Howell's earlier theory regarding the rôle of prothrombin in blood clotting. The latter view was supported by recent work of Patek and Taylor."

I believe that this statement is somewhat inaccurate. In 1914 Howell concluded that the prolonged coagulation in hemophilia was due to a subnormal amount of prothrombin. In 1926 Howell and Cekada dismissed this theory and proposed that the clotting abnormality resided in a peculiar stability of the platelets. More recent studies (Patek, A. J., Jr., and Stetson, R. P.: *J. Clin. Investigation* 15:531 [Sept.] 1936. Patek, A. J., Jr., and Taylor, F. H. L., *ibid.* 16:113 [Jan.] 1937) imply that the platelets in hemophilia are normal and, secondly, that the plasma of hemophilia is deficient in a substance present in the noncellular, normal plasma. This clot-accelerating substance is precipitated with the prothrombin complex, but it is not identified as prothrombin. Indeed, studies in progress imply that the two are distinct.

Chronic Disease, Welfare Island, City
of New York Department of Hospitals.

CHRONIC ZINC POISONING

To the Editor:—In his recent paper (Chronic Zinc Poisoning, THE JOURNAL, January 30) Dr. du Bray has apparently overlooked the extensive experimental and clinical studies by myself and my associates dealing with the general biologic aspects of zinc. Not only did these investigations include the development of accurate methods for determining zinc in biologic material and its significance, but special attention was paid to the medical history, physical examination and laboratory studies in a group of men exposed for a long period to zinc compounds uncontaminated by frequently associated impurities:

25. Drinker, C. K., and Fairhall, L. T.: Zinc in Relation to General and Industrial Hygiene, *Pub. Health Rep.* 48: 955-961 (Aug. 11) 1933.

The following is a partial summary of the clinical studies:

"Careful and detailed clinical and laboratory studies on twenty-four workmen exposed over periods of time varying from two to thirty-five and one-half years, to the inhalation of varying concentrations of zinc in the form of zinc oxide, zinc sulfide or fine metallic zinc dust (manufactured, in the main, from ores conspicuously low in lead and low in cadmium) have revealed no acute or chronic illnesses ascribable to zinc. The workmen, chosen to represent varying types and degrees of exposure to zinc, proved on the whole a vigorous, healthy lot of men, giving no histories of significant past illnesses and showing only such general physical conditions as one would expect to find in any similar group of men of the same ages, of the same social status, and doing approximately the same amount of physical work in an atmosphere with a moderate amount of dust but with no exposure to zinc. This fact is especially significant, indicating, as it does, that ill health ascribed to zinc, particularly the so-called chronic zinc poisoning often referred to in the literature, is in all probability due to toxic impurities, such as lead, cadmium, arsenic and antimony, which commonly contaminate zinc ores, and not to zinc itself.

"Our study demonstrates that zinc workers absorb and excrete zinc in amounts considerably over the normal, and that they maintain constantly a blood zinc content slightly higher than normal. It is apparent, however, from our investigation that abnormal amounts of zinc may enter and leave the body for years without causing symptoms or evidence, which can be detected clinically or by laboratory examinations, significant of gastro-intestinal, kidney or other damage. The fact should be stressed that the amounts of zinc in the urine and the feces of zinc workers represent increased amounts of a normal urinary constituent, and not the presence of a metal abnormal to living cells and to metabolic processes."

Our subsequent experience with these men has confirmed these conclusions. Metal fume fever (a reaction common after the inhalation of finely divided inorganic and organic compounds, magnesium oxide or threshing dust, for example, occurs with rare exceptions after only initial exposure to zinc oxide. The discomfort of those affected is so slight that it is difficult to persuade them to report for examination and study. There has been no absence from work from such reactions. Contrary to the quoted experiences of Dr. McCord (who dealt with zinc mixtures of admittedly unknown composition), we found the

relative incidence of gastric and duodenal ulcer in the group handling zinc products lower than among those otherwise engaged.

Several features of the case report by Dr. du Bray are noteworthy:

1. The slight hypochromic anemia and basophilia reported were not observed in our series.

2. The subjective improvement of the patient after returning to the country is essentially that which many of us would obtain on vacation.

3. Most surprising was the absence of severe caustic damage to the skin from zinc chloride, well known for its destructive effects when in direct contact with tissue. One would almost as readily expose a workman's skin to silver nitrate or trichloroacetic acid as to zinc chloride.

4. The very sensitive methods for the estimation of zinc in biologic materials have never demonstrated skin absorption of zinc compounds.

CECIL K. DRINKER, M.D., Boston.

Dean and Professor of Physiology, Harvard
University School of Public Health.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POSSIBLE ESSENTIAL EPILEPSY AS CAUSE OF DEATH

To the Editor:—Please advise me what diseases might have been responsible for death in the following case: A primipara, aged 25, three months pregnant, suddenly went into a coma and died in about six hours without regaining consciousness. There were no convulsive movements; there was marked frothing at the mouth but no vomiting. There were two previous attacks, ten days and three weeks previously. The first, which had a duration of ten minutes, was characterized by restlessness and confusion. There was no loss of consciousness. In the second one she lost consciousness for fifteen minutes. I was unable to arouse the patient. The extremities were flaccid. The pulse rate was 70. Ronchi were present throughout the chest. The blood pressure was 120 systolic, 80 diastolic. The rectal temperature was 97. There were no burns about the mouth. There was no nystagmus. The pupils were moderately dilated but equal in size. Abdominal examination did not detect masses or muscle spasm. The kidneys were not palpable. All reflexes were gone. Urinalysis was entirely negative (unfortunately, no blood sugar was taken). The autopsy, which was limited to the brain, showed no abnormality (gross examination only). The patient was in good health prior to the present illness. There was no appreciable change in her status during the six hours that she lived. Please omit name.

M.D., New York.

ANSWER.—From the evidence presented it is impossible to be certain as to the cause of death in the case described. If one omits suicidal poisoning, of which there is no direct indication, the most likely of several possible causes would seem to be essential epilepsy.

The fact that the patient was pregnant immediately suggests eclampsia, but this disease is improbable for several reasons. Eclampsia is rare before the sixth month of gestation; this woman had been pregnant only nine weeks when her symptoms first appeared. The arterial pressure was normal; there was no albumin, blood or casts in the urine. Edema, hyperemia, thrombosis and hemorrhage, often found in eclamptic brains, were apparently absent. However, the lack of more complete anatomic evidence prevents absolute exclusion of eclampsia gravidarum as the cause of this death. And in the absence of examination of the blood, hypoglycemia cannot be excluded as a possible cause.

Heart block of sufficient grade to kill is unlikely in the presence of a pulse rate of 70 per minute (one assumes it was regular) and a normal blood pressure. The same can be said for the rarer and more bizarre disturbances of cardiac mechanism; for example, recurrent ventricular fibrillation. Frothing at the mouth and rhonchi throughout the chest mean pulmonary edema. While this might be of cardiac origin, it is also characteristic of convulsive states in general, including epilepsy.

Essential epilepsy beginning at 25 years of age is by no means rare. Coma, dilated pupils, absent reflexes, flaccid limbs, all are part of the epileptic fit. As a cause of death it has been described frequently. Information obtained from more or less complete postmortems in such cases is commonly meager. However, hyperemia of the brain is regularly present and often has been marked.

It seems, therefore, that although a positive diagnosis of essential epilepsy is not permissible there is more evidence in favor of it than of any other condition that readily comes to mind.

FUNCTIONAL VASOSPASTIC VASCULAR DISTURBANCE

To the Editor:—I will appreciate greatly any information or suggestion that you can give me regarding the etiology, the diagnosis or especially the treatment in a case in which the hands and feet are always cold and sweating. The patient is a woman, aged 22, about 5 feet 9 inches (175 cm.) tall and vigorous in appearance. She is a college student and engages in school athletics very successfully. There is no inactivity of the bowels and no menstrual irregularity or pain. She weighs 159 pounds (72 Kg.) and has never weighed more. Physical examination is negative except for a chronic infection of the tonsils of which the patient has been unaware. Much pus can be expressed from the tonsils. The blood pressure is 125 systolic and from 10 to 20 diastolic. Evidently there is a marked vasomotor abnormality. Is it likely that there is a glandular factor in the etiology? Would tonsillectomy promise anything of relief from the complaint. Please omit name.

M.D., Washington.

ANSWER.—The condition described belongs to that indefinite class of vasospastic vascular disturbances probably functional in origin. There is no definite etiology. In some cases focal infection may play a part, in other cases some form of neurosis. One might consider Raynaud's disease and acrocyanosis, although there are no symptoms characteristic of these in this report. Hypothyroidism or hyperthyroidism might be looked for. One might look for a cause for the high pulse pressure. It is suggestive of aortic disease at the age of the patient, although the physical examination is described as negative.

It would be advisable to test for peripheral vascular permeability with injections of histamine to rule out actual obstruction. In the absence of any positive observations, mecholyl in 200 mg. doses two to three times daily might be tried. Occasionally abdominal cramps follows its use. In some patients good results have been obtained with injections of pancreatic tissue extract. It comes in ampules. Physical therapy in the forms of massage, active and passive exercise, exposure to a therapeutic lamp or the passive vascular exercise variable pressure cabinet may be tried. In cool weather, woolen gloves and woolen stockings may be required if the sensation of cold is disagreeable.

STERILITY

To the Editor:—A man, aged 30, and wife aged 31, complain of sterility. The past history is irrelevant. Habits and sexual experiences are normal during three years of married life, except for frigidity on the part of the wife. Physical examination of the wife revealed hyperthyroidism, which was corrected. Physical examination of the husband revealed no pathologic changes. Laboratory examinations gave negative results. Analysis of the semen revealed a volume of 4 cc., appearance and viscosity normal, and pH 8.2. The motility after four hours was excellent, after twelve hours very good, after thirty-six hours from 12 to 15 motile spermatozoa per high power field. The count per cubic centimeter was 80,000,000, total for ejaculate 320,000,000, and 90 per cent were morphologically normal. In spite of repeated semen analysis, post-coitus specimens revealed no motile spermatozoa. Please omit name.

M.D., North Carolina.

ANSWER.—Undoubtedly something in the vagina destroys the motility of the spermatozoa. There are two possibilities. Either the vaginal secretion or the cervical contents are inimical to the spermatozoa. Spermatozoa survive best in an alkaline medium. The endocervical contents are practically always alkaline and hence are not hostile to the spermatozoa. On the other hand, the vaginal secretion is normally acid and if there is an excessive acidity the spermatozoa may not retain their motility very long. This is especially true if for some reason the spermatozoa are not deposited on the cervix during the ejaculation. Normally vaginal acidity plays no part at all, provided spermatozoa reach the cervix promptly. If, however, the cervix is not readily accessible to the spermatozoa, as for example in cases of anteversion, anteversion, elongation or prolapse of the cervix, these abnormalities may have to be corrected. Nevertheless a simple procedure to carry out first is to have the patient take a prolonged alkaline douche each time just before coitus is to take place. This may diminish the acidity of the vagina sufficiently to permit the spermatozoa to reach the cervical canal. If alkaline douches do not help overcome the sterility in this case, it is best to inseminate the spermatozoa directly into the uterus. This is a simple pro-

cedure but it must be carried out under aseptic precautions as possible. The semen should be brought as soon after ejaculation as possible in a clean cold cream jar which has previously been boiled and kept clean. It is best to inseminate sperm every second day from the tenth to the eighteenth day of the menstrual cycle. Only a few drops should be inserted into the uterine cavity just beyond the internal os through a uterine cannula.

POSSIBLE CHRONIC PANCREATITIS

To the Editor:—A woman, aged 57, complains of distress in the abdomen following the taking of food, hot flashes, weakness, loss of weight and strength, and spells of nausea and vomiting. Her trouble first started with the hot flashes when she stopped menstruating about ten years ago. These have persisted, coming regularly about every day and night since then, having moderated somewhat in the last two or three years. During the summer she wakes up practically every time she has one of these, but during the winter she usually sleeps rather well. She has been given theelin (estrone) in large dosages with no effect. Her other symptoms are of relatively recent onset. About a year ago she began having distress off and on following her meals. This has progressed until at the present time she has distress following almost every meal but seemingly worse in the evening. This distress seems to be gas in the large bowel and does not seem to be associated with any particular type of food. She has found nothing that will give relief. She has become weak and tired and worn out in the past six months, possibly because she has eaten so little. She lives on a farm and used to do considerable outside work as well as housework; now she cannot do even her housework. She has lost approximately 30 pounds (13.6 Kg.) in the last eight months. On several occasions in the past six months she has had spells of extreme nausea, vomiting and diarrhea, and on at least three occasions following the vomiting and diarrhea has been unconscious. The worst spell happened about two months ago. About two hours after a light evening meal she started vomiting and in about three hours became unconscious and was unconscious for more than forty-five minutes. She had some diarrhea and the vomiting continued until noon the next day. Following this episode she was in bed for about two weeks. She had no fever and no tenderness or pain in the abdomen. At times she has an extreme nausea and feels as if she would have vomiting and diarrhea but doesn't. Sometimes these spells of nausea last from eighteen to twenty-four hours. Always after these spells she is weak and has to stay in bed. Her bowels have been very regular; there has not been constipation. The gallbladder was removed in 1932 following four or five years of rather typical symptoms of cholecystitis. Following this she was unusually well for three years. As a girl she remembers having had numerous spells of diarrhea. Her father died at the age of 74 and her mother at the age of 75, both of carcinoma of the stomach. One sister has a multiple diverticulitis, for which it was necessary to do a colostomy several years ago. One sister has had her gallbladder removed. Two brothers have had peptic ulcers. Several other brothers and sisters have various indefinite gastro-intestinal symptoms. The patient appears tired; the skin has a somewhat darker appearance than it used to, although this is not noticeable to any one who did not know her previously. Her skin seems somewhat dry. General physical examination is negative, the heart is normal, the blood pressure 125 systolic and 80 diastolic on repeated readings. The abdomen is normal except for some slight tenderness over the colon. The generative organs appear to be normal. The red blood cells number 4,500,000, hemoglobin is 92 per cent and the white blood cells number 5,750, with 78 per cent polymorphonuclears and 21 per cent lymphocytes. The urine is normal on repeated examinations. The stools are negative for blood on repeated examinations. A basal metabolism test gave a reading of plus 25 but the technician felt that this reading was not correct as the patient was nervous and restless all during the time it was being done. It was repeated the next morning with a reading of minus 20. The blood sugar one morning was found to be 38 mg. per hundred cubic centimeters, on another morning 43 mg. Following this a dextrose tolerance test was done with the following readings: fasting blood sugar 38 mg., one-half hour 50 mg., one hour 143 mg., two hours 79 mg., three hours 77 mg., four hours 75 mg., five hours 43 mg., six hours 60 mg. The blood nonprotein nitrogen was normal. X-ray examinations of the stomach gave normal results. A colon series showed considerable spasticity of the ascending and transverse colon, with loss of haustration of the descending colon. She was seen by two competent internists, who could not agree on the diagnosis. One felt that probably the condition was endocrine imbalance with possibly some hyperinsulinism. The other felt that most of the symptoms could be explained on the basis of colitis and that the low blood sugar readings were simply due to the low food intake. She was placed on a smooth diet relatively high in fats and low in carbohydrates with frequent feedings. She was given belladonna and phenobarbital before meals and placed at rest. She has been on this treatment for about three weeks and has made some progress but not as much as was hoped for. She still has distress, although not as marked and not every day. She has had two spells of nausea, which were of relatively short duration. She has not regained any strength although she has been taking much more food than previously and she also continues to lose weight. Any suggestions you might have as to diagnosis or treatment would be greatly appreciated. Please omit name.

M.D., Iowa.

ANSWER:—The gastro-intestinal symptoms would fit in with disease of the pancreas—possibly chronic pancreatitis. Colonic irritability, manifested by abdominal distress, cramps, nausea or vomiting, with or without diarrhea, is frequently associated with disease of the pancreas. The recurring attacks of unconsciousness, the low blood sugar readings, especially at the five and six hour periods, and the fasting low blood sugar are certainly sufficiently characteristic to suggest the diagnosis of

hyperinsulinism. It is hardly probable that disease of the adrenals with hypoglycemic reactions need to be considered because of the normal pressure and the absence of other symptoms.

The history of gallbladder inflammation followed by a cholecystectomy even though followed by three years of well being, does not of necessity rule out the possibility of pancreatitis. The subsequent development of hypoglycemic reactions of pancreatic origin creates a complicated picture which theoretically might be explained in one of two ways. There may be two distinct processes, although related, a pancreatic neoplasm which may compress the pancreatic duct distal to the ampulla and thereby lead to acinous atrophy and islet hypertrophy. The latter may cause hyperinsulinism. Or she may have a small islet tumor causing hyperinsulinism. The diet consists of a relatively low carbohydrate content in the form of 5 to 10 per cent vegetables and fruits, fruit juices, and a high fat diet.

Seale Harris recommends in cases of loss in weight from 2 to 4 ounces of ice cream every three hours while awake. Harris further states in his most recent article on hyperinsulinism (*Ann. Int. Med.* 10:514 [Oct.] 1926) that, if the patient does not respond to this regimen, exploration of the pancreas for an adenoma is advisable. Insulin has been used by some. Reference to the article mentioned will yield information as to the various medicaments used and the rationale of their use.

PHLEBITIS WITH SWELLING OF LEG

To the Editor:—A man, aged 78, has considerable edema of the right leg, extending well above the knee, and it is becoming increasingly hard for him to have shoes fitted. Elastic stocking when put on in the morning, at a time when the edema is somewhat less, causes almost painful swelling over the knee and in the thigh. Otherwise apparently there is but little discomfort from it. There are a number of thin walled tortuous varicosities in the skin, but no other veins are visible. Because of the thinness of the walls of these blood vessels, which are close under the epidermis, the injection treatment of the varicosities, which had begun with hopes of giving some relief, were discontinued. The patient also has polyps of the rectum and bilateral hydroceles. The left leg is entirely normal. The present edema of the right leg began five years ago. Urine examination is negative. The heart condition is not remarkable. He has had extrasystoles for three years. The blood pressure is 120 systolic, 80 diastolic. He has been put on 1 cat unit of digitalis daily for several weeks, without any improvement. Could you advise me as to cause and treatment? Would ligation of the saphenous vein help? Please omit name.

M.D., California.

ANSWER:—There has probably been a phlebitis involving the deeper veins with consequent thrombosis and obliteration. Possible intrapelvic obstruction must be ruled out. The condition is best left alone as far as surgery or injections are concerned. A well fitting elastic stocking could be tried, but it must not interfere too much with the return circulation through the superficial veins. There is no reason for the digitalis and it is best omitted. It is a mechanical condition which can be alleviated but not permanently remedied and does not call for the administration of any diuretic drug. Digitalis is not a diuretic per se.

ONION TASTE TO MILK

To the Editor:—I am interested in the experiments related in *THE JOURNAL*, January 9, on page 136, "That Garlic Odor." In the last paragraph it is stated that "30 Gm. of raw domestic onion can be swallowed in capsules and no odor detected on the breath." How can the onion taste to milk be explained when the cows eat onion grass? I know for a fact that the students of a college in Virginia could not drink the milk served because of a strong onion taste.

LYMAN WEEKS CROSSMAN, M.D., New York.

ANSWER:—The observation that milk from cows eating onion grass has an onion taste is undoubtedly correct. The probable explanation is that a sufficient amount of volatile oil from the ingested grass has reached the blood to allow its excretion by the mammary gland. Many substances are excreted into the milk, including numerous drugs, salts, anesthetics, metals, volatile oils and lipid-soluble substances. Cows fed large amounts of cod liver oil may produce milk that tastes and smells of the fish oil. It is common knowledge that fat-soluble pigments and carotenoids from plants enter the milk and give the yellow color to butter. Every dairy farmer is aware that the diet of the cows affects the color, odor and taste of the milk. Human milk likewise may contain the odor of alliacious oils present in the mother's food. Whether or not it does so depends mainly on the amount of substance ingested.

Again, the cow consumes large quantities of these greens. Also, onions vary considerably in their content of allyl-propyl disulfide, and the wild vegetable may contain a higher percentage of volatile oil than the domesticated form. As this oil

is lipid soluble, the higher fat content of cow's milk as compared to human milk may be an additional factor in the presence of onion odors.

The experiments referred to in the inquiry were merely quoted by Goodman and Bearg in their communication to THE JOURNAL. If it should be found to be generally true that 30 Gm. of raw domestic onion can be swallowed in capsules without affecting the odor of the breath, this might mean only that this amount is insufficient.

ANGINAL PAIN IN HEART DISEASE

To the Editor:—I would appreciate some information regarding certain cases showing symptoms of angina pectoris. There is perhaps an initial attack of mild anginal pain relieved by rest in bed from which the patient is free for several months, but with increasing dyspnea on effort until there is a recurrence, at first slight and transient and coming on several hours apart gradually increasing in severity, length and frequency until a doctor is called. When the patient is first seen the attacks will last about five minutes and be that far apart, the pulse but little accelerated, the heart tones normal in character and location. Two ampules of amyl nitrite will give no relief and if $\frac{1}{100}$ grain (0.0065 Gm.) of glyceryl trinitrate is given by mouth the patient may be made uncomfortable, restless and apprehensive. The pulse may jump to 120. There is not the classic ghastly pallor, the eyes staring with terror and anxiety, the bodily rigidity. The patient may bend forward in bed, the arms slowly writhing with tense muscles, the face suffused, the eyes tightly closed with a frown and the patient uttering a low moan. The pain is viselike beneath the left border of the sternum, radiates to the left shoulder and down the arm to the hand, and will take perhaps more than a grain (0.065 Gm.) of morphine to control, in one who is in no way addicted to the use of opiates. Urinalysis will show a marked transient glycosuria. With absolute rest in bed there will be no repetition of the attack. What has probably happened and what is the prognosis?

H. A. HASKELL, M.D., Windsor, Calif.

ANSWER.—The question is not quite clear. If the symptoms mentioned occurred in chronological order in a patient who was under observation, a fairly reasonable explanation may be offered. With this assumption it is probable that the patient suffered for a time with anginal pain, the angina of effort. It is assumed that this type of pain is due to a general reduction of the coronary circulation due to anatomic changes in the coronary vessels, and the discomfort is usually quite amenable to rest in bed and to reduced activity. The increasing dyspnea on effort would indicate that the myocardial failure due to the impaired coronary circulation was constantly progressing. Then, after several months of this, the patient had an acute coronary occlusion. The relatively slow onset of the occlusive symptoms may be explained by the assumption of a slowly spreading thrombosis, so that several hours may be consumed in reaching the height of myocardial infarction. The pain of coronary occlusion is not relieved by vasodilators and the inhalation of amyl nitrite plus glyceryl trinitrate beneath the tongue would be likely to add to the discomfort in such a situation. Repetition of this attack would not be likely to occur unless there was additional thrombosis. Indeed, previously existing anginal pain has been known to disappear following a frank coronary occlusion.

The prognosis is distinctly unfavorable in general but must be based on the individual case.

ALCOHOL IN URINE

To the Editor:—If the urine in the bladder contains 0.18 per cent alcohol at necropsy, would that be presumptive of acute alcoholic intoxication? Can you refer me to any authority on the subject of alcoholic contents of viscera and body fluids at postmortem?

HOWARD K. SHROM, M.D., Detroit.

ANSWER.—Assuming that the analysis indicates 0.18 per cent by weight in the urine and that the individual did not die within thirty minutes after beginning drinking, it is apparent that the individual was but moderately under the influence of alcohol at the time of death. This percentage is usually associated with definite psychologic inferiority and with but slight impairment of muscular coordination. Furthermore, this amount of alcohol could not be considered as a cause of death, since death from alcohol rarely occurs until body fluids contain more than 0.6 per cent. If we consider the more remote possibility of death occurring within thirty minutes after starting drinking, there would have been insufficient time for the distribution of alcohol, and the urine would have contained much less than the blood. For this reason, examination of the blood is an important adjunct when the time factor is unknown.

About one hour after drinking, alcohol becomes fairly uniformly distributed in the water of the body and it is evident that a man weighing 150 pounds (68 Kg.) having 0.18 per cent in his urine must have consumed at least $150 \times \frac{2}{3}$ (fraction of

water in body) $\times 0.18$ per cent = 0.18 (pounds of alcohol in body); = 2.9 (ounces of alcohol by weight; = 3.6 (ounces of alcohol by volume, alcohol having a specific gravity of 0.8).

The distribution of alcohol in various tissues of the body has been discussed by:

INTERMITTENT CLAUDICATION

To the Editor:—What can one do in the treatment of intermittent claudication? A man, aged 78, began to find about four years ago that on walking one or two blocks he experienced an agonizing ache in or about the right hip joint, which he at first feared might be due to emburcation of the head of the bone or the acetabulum but learned in the course of the succeeding three or four years that more than the joint surfaces was involved. At length the pain extended to surrounding structures and did not always originate in the joint itself but up above and behind the joint, affecting the lower portion of the gluteus maximus muscle and in time (two or more years) began to be accompanied by numbness, which extended to and involved the outer three fourths of the foot on that side. The inferior half of the gluteus maximus would become quite numb at these times. Sitting down for ten or twelve minutes would see it depart, leaving no trace, to return again under similar conditions. Latterly it has begun to affect the left side also, and for about four nights it has invaded the left leg and foot some time after he retires, at which times the numbness appears to be accompanied by an agonizing ache, which may be in one of several situations but is usually in the front part of the leg about 4 inches above the ankle joint. Walking, however, causes the aching and numbness to reappear in the calves and in the thighs—it does not appear to be so much localized as it was earlier. After ten or twelve minutes' rest it disappears entirely until walking is indulged in again, or until he retires to bed. After a round of this kind, if he rises and walks about for ten or twelve minutes he can lie down and sleep soundly. He has a fair appetite and in other respects feels as well as usual. A while back he had some trouble (annoyance) with extrasystoles, but these disappeared on taking pepsin and hydrochloric acid after meals for a week or two. He has no shortness of breath on exercise; he can lift as heavy a load as ever. He has to rise once, about 4 a. m., to urinate. In my library (of about 500 volumes) only one writer gives anything that one could call a description, but only indefinite suggestions for treatment. This is Nascher, *Geriatrics*. Is there a treatment? Is the disease amenable to any treatment? What is the pathology and the cause? I omitted to state that in the limb in which the manifestations appear there is a lowered temperature. MILLARD F. CUPP, M.D., Clarksburg, Ind.

ANSWER.—Intermittent claudication is a symptom of arterial insufficiency which is produced by disease of the arteries to the extremities, either inflammatory in nature, that is, thromboangiitis obliterans, or degenerative in nature, that is, arteriosclerosis obliterans. It is characteristically produced by exercise and relieved by rest. It does not occur while the patient is at rest, nor does it occur while the patient is standing. It is quite probable, therefore, that the patient whose symptoms are described does not have intermittent claudication. This would be a certainty if pulsations in the arteries to the extremities were found to be normal and if there were no abnormal pallor of the feet on elevation of them or abnormal rubor when they were dependent, as these signs are manifestations of occlusive arterial disease. Since the patient has pain while at rest and numbness of a portion of the foot indicative of nerve involvement, it appears that the process responsible for the symptoms is more probably in the structures in the spine, pelvis, hip joint or upper part of the femur. These areas should be examined carefully and roentgenograms made. In a person of the age of the patient whose symptoms are described, one should suspect metastatic involvement of the bone.

The treatment of intermittent claudication is not entirely satisfactory, but the distance which patients with intermittent claudication can walk is ordinarily increased considerably by the administration of tissue extract (Barker, N. W.; Brown, G. E., and Roth, Grace M.: *Am. J. M. Sc.* 189: 36 [Jan.] 1935). If the patient has an occlusive arterial disease, it is advisable to attempt to increase the circulation to the extremity with the method described by Brown (*Surg., Gynec. & Obst.* 58: 297 [Feb. 15] 1934) with the exception that sympathectomy and the intravenous injection of typhoid vaccine are not ordinarily advisable in older persons whose occlusive lesion is due to arteriosclerosis. Intermittent pressure and suction may be of value (Allen, E. V., and Brown, G. E.: *Intermittent Pressure and Suction*, THE JOURNAL, Dec. 21, 1935, p. 2029).

ALLERGIC DERMATITIS

To the Editor:—A boy in apparently good health has a widespread papulosquamous eczema. The areas involved are the forehead, angles of the jaw, anterior part of the chest, flexor surface of the forearms, the creases at the knee and elbow, and the outer portion of the legs. On the leg, where the child rubs them on the bed and chairs, the lesions are moist and weeping; otherwise the lesions are dry, slightly elevated and scaly. The child was premature (thirty-four weeks) and weighed 4 pounds 12 ounces (2,155 Gm.) at birth. For two weeks the child was fed on breast milk and, as the supply failed, was put on evaporated milk and karo, with small doses of thyroid, halibut liver oil and viosterol and orange juice. He was given cereal (pablum) at 4 months, vegetables (Heinz) at 5 months and egg yolk at 6 months. At present he is 9 months old, weighs 22½ pounds (10 Kg.), is 29 inches (74 cm.) in height, has six teeth, sits up alone, and in general shows a normal mental and physical development. The present diet is 24 ounces of whole milk, 8 ounces of water and 3 tablespoonfuls of karo, cereal (1 tablespoonful of pablum), vegetables (3 teaspoonfuls of strained carrot and 3 teaspoonfuls of some strained green vegetable), fruit (3 teaspoonfuls of strained fruit, as prune or apricot or apple). He also gets the juice of one orange and ten drops of halibut liver oil with viosterol. When the child came home from the hospital he had several small areas of rough skin on the forehead and legs. Since then the condition has grown steadily worse. Every article of diet has been omitted for at least ten days, with no change except that I noted that with egg yolk there was a definite aggravation and it has been since omitted. The soap has been changed, as also the brand of halibut liver oil and viosterol, and the type of oil used on the skin. Whole milk has been substituted for the evaporated milk. All aluminum cooking pans have been eliminated. There are no other allergic symptoms in the child. He has had no head colds. After vaccination and diphtheria immunization there was no reaction. The child's great grandfather (paternal) had hay fever, the maternal grandfather had asthma, and a great aunt is sensitive to strawberries. Locally I have used calamine lotion, boric acid ointment, graphite ointment and rosewater ointment. As this is my own son, I am of course certain of all the facts stated as to diet and history.

M.D., Rhode Island.

ANSWER.—This is probably atopic dermatitis; that is, dermatitis caused by sensitization to food or possibly to environmental allergens. It would be well to do scratch tests with all the foods the baby is eating and with the environmental allergens, such as silk, kapok and feathers. If the scratch test to milk is negative, an intracutaneous test with milk should be done, as this is often positive when the scratch test is negative. The diet should then be regulated in accordance with the skin tests, and feathers and dust should be removed so far as possible from the environment, no matter what the skin tests show. If skin tests are not done, the following diet, planned in accordance with the food sensitivities that most of these babies show, may do some good: one of the proprietary milk free foods (cemac, sobee and the like); oatmeal or cornmeal; string beans, carrots and bananas; cevitamic acid tablets, and halibut liver oil with viosterol.

It is difficult to prescribe local treatment without seeing the child, but the following prescriptions usually work well.

For the face:

Crude coal tar.....	8 Gm.
Zinc oxide	16 Gm.
Starch	32 Gm.
Petrolatum	4 ounces (125 Gm.)

For the arms and legs:

Salicylic acid	2.6 Gm.
Mercurochrome crystals	1.3 Gm.
Aquae, q. s.	
Hydrous wool fat.....	
Petrolatum	2 ounces (62 Gm.)

LACTIC ACID MILK AND INTESTINAL
FERMENTATION

To the Editor:—What is the difference between lactic acid milk, acidophilus milk, sour milk and buttermilk (sweet and sour)? Can pasteurized milk sour, or does it putrefy? When one wishes to change the intestinal flora of a patient with intestinal fermentation accompanied by discomfort and distention of the abdomen, and lactic acid milk cannot be obtained for treatment, will buttermilk or sour milk serve the same purpose? Will milk acidified with lactic acid change the flora as well as a culture of the lactic acid bacillus?

M.D., Pennsylvania.

ANSWER.—Lactic acid milk is cow's milk (fresh or pasteurized) to which lactic acid has been added in the proportion of from 3 to 3.5 cc. to 100 cc. of milk. Acidophilus milk is sterilized milk which has been fermented by a pure culture of *Bacillus acidophilus*. Buttermilk, with varying degrees of acidity, is a product of indefinite composition produced by the "souring" action of *Streptococcus lactis* and *Bacillus bulgaricus*. Lactic acid milk is so easily prepared, it should be available for use as desired in treating the condition described. Change of the intestinal flora to a predominantly aciduric type requires the ingestion of large amounts of living *Bacillus acidophilus* and the feeding of at least 100 Gm. of lactose or dextrin daily. A preparation of acidophilus milk supplemented with lactose or

dextrin is the most effective means of producing this transformation of the intestinal flora.

As the term intestinal fermentation is vague, a direct answer to the question of treatment cannot be given. Buttermilk or sour milk might cause either an increase or a decrease of intestinal gas. Transformation of the flora by these agents is uncertain.

Further information is given in the article on "Lactic Acid-Producing Organisms and Preparations" in *New and Non-official Remedies, 1937*, page 274.

DUODENAL ULCER AFTER BURNS

To the Editor:—I treated a man seven years ago for an extensive burn over the chest and abdomen. The damaged area must have involved at least one third of the surface of the body. Since his accident he has had quite a bit of digestive trouble, which is probably a duodenal ulcer. About a week ago he had a hemorrhage from his stomach and duodenum. Can you give me an estimate of the percentage of burn cases in which duodenal complications develop? The patient may carry his case to court for disability and I should like to have some authoritative information with regard to the case.

M.D., Georgia.

ANSWER.—There is considerable difference of opinion regarding the frequency with which burns are complicated by duodenal ulceration. One author states that of all fatal burns 6.2 per cent are complicated by ulcer formation. In one series of sixty-eight patients, two had duodenal ulcers. In another series of 248 burned persons, the complication occurred only once. Because the development of the ulcer during the course of the burn is not accompanied by the symptoms so characteristic of the lesion as it is usually observed, its presence in the acute stages is often not suspected. Hemorrhage is usually the first symptom of duodenal ulceration occurring during the acute stage of a burn. Acute perforation may be the first evidence of its presence. While duodenal ulceration is not a common complication in burns, it occurs with sufficient frequency to justify the conclusion that there is a definite relationship between the two conditions. There is some experimental evidence to support this clinical observation.

DIAGNOSIS OF SYPHILIS

To the Editor:—I have under my care a man, aged 39, weighing 172 pounds (78 Kg.), who came to me Feb. 28, 1936, with a lesion on the left side of the corona, which, the laboratory reported, showed large numbers of *Spirochaeta pallida*. The man had infected his wife before he came under my observation and I have had the two under my care since then, both taking active treatment. I have used the continuous plan of treatment as recommended by the U. S. Public Health Service. In all the husband has had twenty-two injections of 0.6 Gm. of nearsphenamine and twenty-six injections of a bismuth compound in the gluteal region. By March 16 his original lesion was entirely healed. October 17 he had an illicit intercourse and on November 24 another one with the same partner. During these dates he was taking intramuscular injections of the bismuth compound. November 25 he noticed a slight red spot on the right side of the corona and by November 28 this was an open lesion. December 5 I sent him to the laboratory again and the laboratory reported spirochetes in this lesion. Since the patient has had no intermission in treatment and since the second lesion does not occur in the same lymphatic drainage area as the first lesion, I am at a loss to account for it. The question that I hope you can help me to decide is "Is this a recurrence on the opposite side of the corona which I am unable to find any account of in the textbooks, or must I regard it as a new infection which has occurred in spite of his continuous treatment?" I am unable to obtain an examination of this partner who might have infected him. His wife has pursued a perfectly normal syphilitic course. Please omit name.

M.D., Kansas.

ANSWER.—The data furnished unfortunately are not sufficient to allow an unequivocal answer. No mention is made as to whether the Wassermann reaction was positive before treatment or what happened to it after treatment was started.

True there is a possibility that this patient is suffering from a reinfection. However, it is well known that infectious monorelapses are prone to occur on the genitalia, and while this is on a different area and in an area that has a different supply of draining lymphatics than the first lesion, there is no reason why this could not be a monorelapse. The fact that we have no information with regard to the Wassermann reactions naturally makes it difficult for us to more than simply mention the possibilities that this is either a monorelapse or a reinfection.

True reinfections in syphilis are exceedingly rare, and under the circumstances we would be inclined to put this down as an acute infectious monorelapse and would recommend that the correspondent start him in on treatment the same as one would a fresh case of syphilis, using the continuous therapy in courses of nearsphenamine followed by courses of a bismuth compound.

Moreover, no mention is made of lumbar puncture and the condition found in the spinal fluid. This, of course, should be done at once. It might assist a great deal in revealing whether

the patient does not already have an involvement of the central nervous system, which would, of course, immediately rule out the possibility of reinfection.

TULAREMIA OR SPOROTRICHOSIS?

To the Editor:—A veterinarian, aged 57, employed by the state of California and working on meat inspection, consulted me Dec. 8, 1936, for multiple nodular enlargement, apparently lying along the lymph channels of the left arm. He had consulted me Jan. 29, 1936, for slight laceration of the second finger of the left hand. This injury showed definite evidence of infection at that time with lymphadenitis noted in the region of the left elbow. Supportive treatment was given and the wound healed without further complication. The present history of the glandular enlargement is not definitely known but the patient first noted these nodules about four months previous to December 8. The nodules are slightly flattened, soft in texture, and freely movable under the skin. There is no discoloration of the skin over these swellings. There is no tenderness and no evidence of fluctuation. They are about half the size of a butter bean, some being smaller. They extend from the middle of the palm of the hand to the axilla. One or two are noticed in the axillary space. December 8 a blood Wassermann test was reported negative. A complete blood count was essentially negative. A biopsy was suggested in this case, but owing to the possibility of a fungal infection it was considered that it might cause a breaking down of the patient's resistance to the infection and produce a sloughing ulcer. The patient's health has been very good and there has been no evidence of a break in the skin of recent origin. Could you suggest any diagnostic measure other than a biopsy in arriving at a diagnosis?

H. R. McMEIKIN, M.D., Lynwood, Calif.

ANSWER:—If the veterinarian had direct contact with wild rabbits, squirrels, sheep, woodchucks, opossums, muskrats, coyotes or certain game birds just prior to the onset of the nodular lymphangitis and axillary adenopathy, the possibility of tularemia should be investigated. The agglutination test for tularemia remains positive indefinitely, although the titer is usually lower (from 1:40 to 1:160) after the lapse of several months from the onset of the disease. A second possibility is sporotrichosis, an infectious, parasitic disease caused by a fungus (*Sporotrichum schenckii*). This disease is characterized by multiple painless circumscribed nodules and abscesses in the skin and subcutaneous tissues, particularly along the lymphatic channels of the extremities. It occurs also in the horse and other animals. Scrapings may be examined directly for the presence of mycelia and cultures made on appropriate mediums. Internal and external iodine therapy appears to be the treatment of choice for sporotrichosis.

Other possibilities are tuberculosis, syphilis and neoplasm. If thorough clinical and pathologic examinations do not provide adequate evidence, biopsy should probably be done. Cultural studies and animal inoculations should be carried out in addition to the microscopic studies of such biopsy material.

DIET LIST FOR ULCER

To the Editor:—Please give me a complete diet list suitable for duodenal ulcer in the interval between attacks and especially after the six month and one year periods. Also please mention lists of foods not allowed. The standard textbooks stress the diet during and immediately after attacks but indicate in only a general way the after-management. It has been my observation that the symptom-free patient will sooner or later discard all dietetic regulation unless given a comprehensive and varied list. Please omit name.

M.D., Pennsylvania.

ANSWER:—A patient disabled with a duodenal ulcer, in a quiescent period, should be allowed the following diet:

Meats: Lamb chop, chicken or lamb.
Vegetables: All kinds, thoroughly cooked except shredded lettuce and raw tomato.
Fruits: All kinds, either raw or cooked, except berries with seeds.
Eggs: In any way except fried.
Fish: Fresh water fish, broiled or boiled.
Soups: Cream soups of all kinds, but no meat soups or meat to be used in the soups.
Cereals: Well cooked cereals or some of the more common, easily digestible dry cereals.
Bread: Must not be too fresh—preferably toasted.
Beverages: Milk, cream, buttermilk or cocoa.
Butter: A moderate amount.
Desserts: Simple desserts such as gelatin, tapioca, ice cream, ices, sponge cake or plain cookies.
Also olives, soda crackers, salted or unsalted, cottage cheese or cream cheese.

The patient is to avoid seasoning of all kinds, pepper and condiments especially, coffee, tea, alcohol in all forms, tobacco, and fried and greasy foods.

Six months after the beginning of treatment, the diet can be as given except that meats should be restricted to an occasional lamb chop or an occasional serving of chicken.

MUSCAE VOLITANTES

To the Editor:—Please give information and references on the condition known as muscae volitantes. A white man, aged 38, complains of black spots before his eyes. The patient's physical condition is good except for four dead teeth; x-ray examination does not show abscessed roots. The patient's weight is 150 pounds (68 Kg.) and his height 5 feet 10 inches (178 cm.). The blood pressure is normal. The present complaint began one and one-half years ago following an attack of influenza of the nervous type. Black spots appear on exertion, in extreme cold weather, at the beginning of a meal and during straining at stool. The bowels are somewhat constipated. The patient had an attack of catarrhal jaundice in 1925. Is this a physiologic disturbance or is it due primarily to constipation? Please advise treatment. Please omit name.

M.D., Pennsylvania.

ANSWER:—Without a statement as to the condition of the vitreous, it is next to impossible to comment at length on the case in question. This may be an instance of simple thickening of the vitreous fibers in which the shadow caused by the crossing of the fibers becomes apparent only when the retinal vessels are engorged. On the other hand, it may be a case of true fibrin or blood clots in the vitreous due to some minor pathologic process. Again, it may be visibility of the blood cells within the retinal capillaries. See Helmholtz's *Physiological Optics*, third edition, translated in 1924, volume 1, page 204. First the patient should be examined by an ophthalmologist.

MINIMUM VISION REQUIREMENTS FOR BUS DRIVERS

To the Editor:—What do you consider should be the minimum vision requirements (Snelling's test type) of drivers of passenger busses on city streets with or without glasses? You need not go to the trouble of discussing night-blindness, diminished visual field or the general health or mentality.

M.D., Alabama.

ANSWER:—There are four minimum vision requirements of drivers of passenger busses which should be complied with:

1. Central vision should be at least 20/20 in one eye and at least 20/40 in the other, with or without glasses.
2. The driver should have normal color vision.
3. The driver should have normal field vision.
4. The driver should have normal stereoscopic vision (most important in judging distance).

TUBERCULOSIS IN DOGS

To the Editor:—In *Queries and Minor Notes* in THE JOURNAL, February 6, page 495, in a discussion of tuberculosis as it occurs in dogs and cats, the statement is made that tuberculosis was observed in approximately 1 per cent of the autopsies on 1,548 dogs. We have conducted autopsies at the North Shore Animal Hospital for sixteen years, and we are still looking for tuberculosis in the dog or the cat. Our experience is analogous to that of a number of other veterinary practitioners in America; consequently, I should like to know where these 1,548 autopsies were held. I do not doubt the existence of tuberculosis in dogs and cats, but observation of the disease in approximately 1 per cent of instances is startling. Even in Holland, according to Jakob (*Innere Krankheiten des Hundes*), in the period from 1906 to 1912 only eleven cases of tuberculosis were found in 568 dogs examined. This is 1.9 per cent.

D.V.S., Illinois.

ANSWER:—The 1,548 necropsies on dogs were reported from the Laboratory of Veterinary Pathology of the University of Pennsylvania by W. J. Crocker. The title of his article and the reference to his paper are as follows: *Three Thousand Autopsies, Corn. Vet.* 9:140, 1919.

IMMUNIZATION WITH SCARLET FEVER ANTITOXIN

To the Editor:—What percentage of protection is obtained from administering the scarlet fever antitoxin to contacts, provided it is given during the early part of the incubation period? Please omit name.

M.D., Texas.

ANSWER:—A prophylactic dose of scarlet fever antitoxin administered to the susceptible infected contacts before any symptoms of the disease, such as sore throat or fever, have developed should prevent the development of scarlet fever on account of the existing infection, although, after two weeks, scarlet fever may develop from a subsequent exposure through contact with a case of scarlet fever or an immune carrier. The protection from a prophylactic dose of antitoxin is transient, lasting about two weeks, at the end of which time the serum is largely eliminated from the body.

If the infected person has developed symptoms such as sore throat or fever, a therapeutic dose of antitoxin should be given. Reports have been made on several institutions in which scarlet fever was successfully controlled by this procedure.

But before the quarantine was abolished between the infected and the noninfected groups the susceptible infected persons who had received the antitoxin to prevent the immediate development of scarlet fever were actively immunized with scarlet fever toxin in order to protect against subsequent infection through contact with carriers known to be living in the institutions.

DIPHTHERIA STATISTICS

To the Editor:—I am wondering whether there has been any record made by the different biologic laboratories as to whether or not there has been any reduction in the sales of diphtheria antitoxin since the discovery of and use of the various preventive methods for diphtheria. If there is, it would assist me and others in urging the use of the diphtheria prevention.

M.D., Texas.

ANSWER.—Information as to the amounts of diphtheria antitoxin distributed by the different biologic laboratories before and after introduction of the various diphtheria prophylactics is not available. Even if available, it might be of questionable significance, since it is possible that more antitoxin is being used in the treatment of the individual case and that more cases are being brought into treatment. Apparently much more significant is the incidence and mortality of diphtheria in cities where preventive inoculation has been used extensively. Among reports bearing on this point is an article entitled "Diphtheria Mortality in Large Cities of the United States in 1935" (*THE JOURNAL*, June 13, 1936, p. 2060), in the last paragraph of which it is stated that "the striking feature in the 1935 diphtheria record appears to be that wherever preventive inoculation against diphtheria is practiced consistently diphtheria deaths well-nigh cease to occur, and in some communities diphtheria morbidity is also reduced to an insignificant figure."

SENSE OF SMELL IN CHRONIC SINUSITIS

To the Editor:—During the World War I contracted sinus infections involving the frontal and maxillary groups. Six weeks following this acute infection I noticed that my sense of smell began to be less acute and finally, over a period of time, the sense of smell completely disappeared. The sinuses drained for years (at intervals) but now they have been inactive for several years and within the last year I have noticed that I am able to detect some odors, very faintly, of course. At times, however, the odors are quite pronounced. I have no nasal deformities and am in excellent health otherwise. The return of this faint sensation of smell is encouraging to me and I would certainly appreciate suggestions from you as to what sort of treatment I might be able to carry out myself in the way of some graduated stimulation to the nerve endings to assist in restoring this sensation. Please omit name.

M.D., New Hampshire.

ANSWER.—In the presence of chronic sinusitis or at least frequent acute recurrences, the sense of smell is apt to disappear or become markedly blunted because, first of all, the secretions by their presence mechanically block the nares and do not permit odors to reach the olfactory area. It may further be that the general inflammation of the lining membrane dulls the physiologic receptivity of the olfactory fibers. The return of the sensation of smell is, of course, encouraging. There are no exercises or types of stimulation, excepting those which are physiologic, that can bring back the sense of smell. The only hope there is of complete restoration is to remove those hypertrophies, polyps or residual infection, which, done well, allows odors to be brought in contact with the schneiderian area.

DIAPHRAGMATIC HERNIA AFTER LABOR

To the Editor:—My wife was recently delivered of her first baby by forceps delivery after twenty-seven and one-half hours of labor. She had never complained of any symptoms referable to the gastric region. During labor she twice vomited "coffee brown" material, which was found to be blood. Shortly after her confinement, roentgenograms were taken of the stomach. The upper fourth of the stomach was found herniated into the thorax through the esophageal hiatus. Since her labor she has had only occasional heartburn, no other symptoms, no vomiting, and the stools are normal. Please omit name.

M.D., Pennsylvania.

ANSWER.—The condition described is a diaphragmatic hernia due to unusual relaxation of the esophageal hiatus. The prognosis is excellent and nothing need be done about the condition unless disturbing symptoms arise. These symptoms may consist of severe pain often after eating, or sharp pain in the chest which resembles that of coronary disease. Not infrequently a diagnosis of heart disease is made on the basis of the character of this pain. Another symptom to which attention should be paid is severe and frequent attacks of heartburn. More important still is hematemesis, which should lead to a careful study for the detection of gastric ulcer. The latter condition is not infrequently associated with a diaphragmatic hernia.

"DOSAGE OF BROWN MIXTURE"

To the Editor:—Permit me to call in question the answer on "Dosage of Brown Mixture for Cough" (*THE JOURNAL*, Dec. 26, 1936, p. 2153). In the first place the unit of measure for antimony and potassium tartrate is grams, not cubic centimeters as recorded in the formula. In the second place, referring to your last sentence, which seems superfluous, what medicine ever does immunize against colds? In the third place, if a 2-year old, for example, received about 1 drachm of the mixture (or about 14/1,000 grain of antimony and potassium tartrate and between 7 and 10 minims of paregoric) every two hours, would he be getting from these two main ingredients of this old time shotgun mixture much more than mild sedation and perhaps some expectorant effect? Certainly if he does not exhibit nausea at the outset he ought to be able to handle a half teaspoonful every two hours without emesis. From one to two drops of brown mixture per year of age would seem pretty homeopathic. Undoubtedly this combination is far from ideal for colds, but if it is wanted in the West Indies, why not give it a chance?

M.D., New York.

ANSWER.—The calculation for antimony and potassium tartrate is correct; there are 7 minims of paregoric in the mixture if the teaspoonful equals 4 cc.

TRICHLORETHYLENE AS CAUSE OF DERMATITIS

To the Editor:—A tailor has developed a severe dermatitis of the hands, which I have traced to use of a cleaning fluid containing trichlorethylene. This fluid is used in cleaning clothes. What can be done to prevent this occupational dermatitis (besides wearing rubber gloves)?

M.D., New York.

ANSWER.—Trichlorethylene, a cleaning fluid, which is sometimes used in the place of carbon tetrachloride, burns the skin of the hands. Avoidance of contact with this chemical in cases exhibiting sensitivity is the only effective preventive therapy. Mildly involved patients can sometimes continue work with protection of the parts by long sleeves and gloves and a protective ointment. The patient may try using some other cleansing fluid, such as carbon tetrachloride, to which he may not be sensitive. Patch testing with the new fluid to be used is advised to determine whether sensitivity exists to it. There is no successful method of desensitization to chemical irritants.

USE OF TETANUS ANTITOXIN

To the Editor:—It is an almost universal practice to administer tetanus antitoxin as soon as possible after an injury. Since the purpose of the antitoxin is not to immunize but simply to neutralize toxin, when formed, would it not be more logical, as well as more effective, to withhold it for several days? Please omit name.

M.D., New Jersey.

ANSWER.—The object in giving antitoxin promptly after injury is to provide the means of neutralizing the toxin as soon as it is produced. This neutralizing effect may be possible for some days, because free antitoxin is eliminated gradually. And immediate neutralization of the toxin undoubtedly favors the destruction by phagocytosis and other means of the toxigenic tetanus bacilli lodged in the injured tissue. Delay in giving antitoxin may provide opportunity for the toxin to form the irreversible union with nerve cells that results in tetanus.

LYMPHOGRANULOMA OF STOMACH

To the Editor:—In *THE JOURNAL*, Dec. 19, 1936, on page 2025 at the end of the second paragraph of "Leukemia of the Stomach Producing Gastric Mucosa," by Rigler, the author states that "the roentgen examination led to a diagnosis of carcinoma rather than of lymphogranuloma." Did he possibly mean lymphogranuloma inguinale? Perhaps what he really had in mind was lymphogranulomatosis.

MARK STERN, Los Angeles.

ANSWER.—Lymphogranuloma—meaning Hodgkin's disease localized to one area—was correctly used in the sentence referred to in the inquiry. Lymphogranulomatosis refers to the generalized form of Hodgkin's disease and is often used as a synonym for multiple lymphoma. There is, of course, no relationship whatever to lymphogranuloma inguinale.

GONOCOCCUS CARRIERS

To the Editor:—Are there any cases on record of persons who have never had clinical symptoms and who have good reproductive ability but who harbor gonococci in the genito-urinary tract?

M.D., Ohio.

ANSWER.—In the adult female without previous clinical diagnosis of gonorrhea, a gonococcus carrier state frequently occurs without clinical symptoms. The carrier state is more likely to occur in a person who has formerly had gonorrhea, and a later new infection often causes no marked subjective symptoms. In the male, however, it seems to be extremely rare for gonorrhea to escape detection by the patient.

Book Notices

Abortion, Spontaneous and Induced: Medical and Social Aspects. By Frederick J. Taussig, M.D., F.A.C.S., Professor of Clinical Obstetrics and Clinical Gynecology, Washington University School of Medicine, St. Louis. Sponsored by the National Committee on Maternal Health, Inc. Cloth. Price, \$7.50. Pp. 536, with 146 illustrations. St. Louis: C. V. Mosby Company, 1936.

Abortion has become not only a great medical problem but also a great social problem. The author has estimated that 681,600 abortions occur annually in the United States. He endeavors to give here all the essential information available. In the historical chapter it is said that one of the oldest abortifacient recipes is still in existence although more than 4,600 years old. Abortion is mentioned in the literature of the ancient Hebrews, Egyptians, Greeks and Romans. Plato desired that his Republic should not consist of more than 5,040 citizens and to maintain a balance of this number he recommended the limitation of births. Aristotle is quoted as having said "If it should happen among married people that a woman who already had the number of prescribed children became pregnant, then before she felt life, the child should be driven from her." Chapters four and five review the anatomy and physiology of early pregnancy, and the pathology of abortion. These two short chapters are essential but they do not offer anything new; as this knowledge has been available for years. Chapters follow on the etiology of spontaneous abortion, prevention, symptoms and signs, and the diagnosis of abortion. The differential diagnosis between spontaneous and induced abortion is at times most important. The presence of fever early in the course of an abortion points to criminal intervention, while hemorrhage in such cases is likely to be more profuse and sudden. There is a tabulated summary of the points in the differential diagnosis between tubal abortion and uterine abortion. The author writes in the chapter on treatment that if the temperature is over 100 F. for more than twenty-four hours the case should be considered septic. Conservatism and a waiting policy in the treatment of uninfected cases is emphasized. Even in septic abortion the delay of a few days to determine the presence of any extension of the infection beyond the uterus is advised. A delay of five days in the evacuation of the uterus, it is said, is always almost possible and does not harm the patient. During this time many cases will terminate spontaneously and in the remainder there will be a better opportunity to build up resistance to the infection. If the temperature has remained normal for from three to five days, emptying of the uterus will expedite recovery and usually do no harm. In case of profuse

bleeding, immediate evacuation of the uterus by the gentlest method possible is indicated and the blood loss promptly replaced by blood transfusions. There is a chapter on operative technic, and then the author discusses the treatment of infection outside the uterus that has resulted from an abortion. The mainstay of treatment at present is rest, good nursing, good diet, blood transfusion, and above all fresh air and sunshine for the purpose of building up resistance to the infection. Perforation of the uterus occurs about once in about every 200 or 300 evacuations of the uterus, and every second or third perforation ends fatally. Of the instruments responsible for perforations, the curet is by far the most common offender. Other complications of abortion include inversion of the uterus, fatal hemorrhage, gangrene of the extremities, and prolonged retention of fetal parts.

The indications for therapeutic abortion have changed from time to time. In the latter part of the nineteenth century the indications were extended to include tuberculosis, heart disease, nephritis and certain forms of psychoses. Since the World War there has been an increased tendency to extend the indications to eugenic and to social and economic factors. The author believes that abortion may also be justified in patients showing asthenia, loss of weight and physical depression, especially if there are several children and the mother has heavy household duties and lacks resources to care properly for children already born. Following chapter twenty, on methods and technic of therapeutic abortion, the prevention of conception by surgical methods of sterilization—resection of the tubes, excision of the uterine cornua and tubal electrocoagulation—is considered. The so-called safe period, he says, is too unreliable to be given serious consideration as the sole method of restricting conception.

In the closing chapters, Dr. Taussig discusses the economic, theological, ethical and legal aspects of induced abortion. There is a chapter on the unusual situation that arose in the Soviet Union following the passage of a law in 1920 which legalized abortion in that country. The author believes that the increase in the number of abortions throughout the world has been due less to laxity of morals than to economic conditions. The underlying faults in our social structure that have led to the present alarming number of abortions can be grouped under the five headings of (1) economic distress, (2) occupational changes, (3) illegitimacy, (4) domestic relations and (5) fear of confinement.

Although, since the war, laws have been passed in some countries widening the medical indications for therapeutic abortion, an amazing situation still exists. The author says that leading obstetricians might almost without exception be sentenced to years of imprisonment if the law as it stands were strictly enforced. He knows of no other instance in which there has been such a universal disregard for a criminal law. There are brief discussions of the abortion laws in various countries. In an appendix are the statutes relating to the procuring of abortion in the states and territory of the United States in 1934. These are followed by an extensive bibliography and a well arranged index.

Die Tsetsefliegen: Ihre Erkennungsmerkmale, Lebensweise und Bekämpfung. Ein Leitfaden für die Praxis. Von Dr. F. Zumpt. Paper. Price, 9 marks. Pp. 149, with 136 illustrations. Jena: Gustav Fischer, 1936.

The tsetse flies are notorious as the insect vectors of the fatal nagana of domesticated mammals and of the equally dangerous sleeping sicknesses of man, both due to trypanosomes in the blood stream and fortunately both confined to tropical Africa by reason of their dependence for mammalian infection on the bite of the infected tsetse fly. Cattle are excluded from 200,000 square miles of Africa by the prevalence of these flies, and the deaths among men have been in the hundreds of thousands annually since the discovery of the cause of the disease in the blood of man by Dutton in 1902. These flies delay the civilization of tropical Africa for a distance of 600 miles on each side of the equator.

The author investigated these flies in the Cameroons in 1935 and this book bears the impress of his contact both with the scientific and practical problems that underlie all efforts to understand these diseases and every effort to control them.

A brief account is given of the anatomy, morphology, feeding and reproduction of the tsetse flies, all of which belong to the

genus *Glossina*, in which the author recognizes twenty species, to a critical account of which about half of the book is devoted. The remainder is concerned with the ecology of the flies in their pupal and winged stages and with the practical measures for control. The female produces from seven to ten larvae in a lifetime of three months, or one about every ten days. The larvae are deposited in damp situations, bore into the substrate several centimeters, pupate, and after from twenty-five to fifty-five days emerge as flies unless perchance destroyed by other parasitic flies whose larvae live in the tsetse pupa. About 50 per cent of pupae in the wild have been found to be destroyed by such parasites. Flies are most abundant during the dry season. The apparent fly density is tested in terms of the catch of flies per boy-hour. Males exceed the females by 4 to 1, and of 156 females only seven carried large pupae, indicating the retiring habit of the pregnant fly.

Practical measures suggested for restricting the ravages of the tsetse fly are: 1. Reducing the population of other carrier mammals that may also become infected. This fails because of forest conditions, migrations of game, and the fact that even very small mammals may serve as hosts. It is also futile and objectionable from the standpoint of conservation of wild life. 2. Cure of infected persons; but this is expensive, difficult to apply in early stages of the disease, and vitiated to a large degree by animal carriers. 3. Restriction of domestic animals and men in fly country to large clearings freed from brush and trees, which are less open to fly invasion. Avenues through the bush and rain forests are cleared for travel but to be effective they must be 1,200 yards in width. Poisoning trees with arsenicals and girdling to induce termite attack reduce the cost of clearing. Smoking out flies from vehicles in specially prepared huts reduces transfer of flies by traffic. These clearing methods require supervision by an ecologist familiar with the territory and species of fly. 4. Trapping flies in continuously operating traps designed to utilize their instincts to seek shelter in a dark background and in the shade, and building pupation chambers for trapping pupae. These have given excellent results in reducing fly density. 5. Biologic control by breeding parasites of the tsetse fly in other flies and releasing them. This method has been tried but awaits tests of its ultimate effects.

Rural Health Practice. By Harry S. Mustard, M.D., Associate Professor, Public Health Administration, School of Hygiene and Public Health, The Johns Hopkins University. Cloth. Price, \$4. Pp. 603, with 28 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1936.

While one may disagree with the author in his attitudes toward a number of fundamental concepts of public health work, it is a pleasure to commend the clear, orderly, comprehensive, understanding and wise presentation that he has made of the practical problems of the health officer in a rural community. The author, in this work as in others, believes in certain principles that do not meet with agreement among physicians in general, such as his approval, at least in part, of making the public health administration a division of a department of public welfare, his approval of the principle of "extra state" funds for local health work, and his rather sweeping condemnation of the principle of health districts, which in at least three states are giving satisfactory service. It is not likely that, even "ultimately," all of the three thousand odd counties of the United States should have full time individual health units; there are too many counties which are now and appear for some time destined to be nothing more than large expanses of landscape peopled by not much of anything. To postulate full time health service for such areas, except in theory, is to cry for the moon. Yet with all that, the book remains a genuine and much needed contribution to the library of the health officer in the small community, rural in character. It would make excellent reading for many a health officer even in the largest communities, since all of them deal with human beings, and human nature is not much different wherever it is found. The problems of the health officer are discussed in a frank, sympathetic manner. The author is well qualified by experience to speak on his subject. His advice is sensible and is given in sufficient detail so that it should constitute counsel of real value for the young administrator, filled with theoretical knowledge, but who has yet to experience his first community contacts, with all the perils of misunderstanding and mistakes that

they involve. The text is salted with enough pointed humor to make it easy and pleasant reading. The book is well documented and well indexed. There are a few good tables, notably some sample budgets that are within reason and represent practical expectations under existing conditions. The volume should be a useful reference book for those engaged in or about to engage in public health work, including the members of medical society committees now cooperating in advisory capacities to state health departments under social security legislation or otherwise.

A Handbook of Tropical Therapeutics. By R. N. Chopra, C.I.E., K.H.P., M.D., Professor of Pharmacology, Medical College, Calcutta. Cloth. Price, Rs. 25/-. Pp. 1,748. Calcutta: Art Press, 1936.

Therapy is taught in the medical schools of India from British and American textbooks based on experience in countries in which climatic and morbid conditions differ from those in the tropics. Medical experience in India indicates that therapy approved in temperate regions is not universally applicable in the tropics, is sometimes disappointing, and may even lead to untoward results. Hence this book, based on fifteen years of graduate teaching and of practice in the Carmichael Hospital for Tropical Diseases by the author with the aid of his colleagues in Calcutta.

This treatise deals with almost the entire range of therapy and is thus a practical vade mecum for the practice of medicine in the tropics viewed primarily from the standpoint of therapeutics. It falls into six parts. Part I is an extended treatment of the action, modifying agencies and administration of drugs; acidosis and alkalosis; chemotherapy; physical therapy; diet and dietetics in the tropics; pyrexia; hypnotics and analgesics; and tonics. Part II deals with helminthic diseases and gives extensive discussions of the chemistry, pharmacologic action, anthelmintic effects, administration and dosage, toxic effect, treatment of poisoning, and precaution and contraindications of filix mas, kousso, carbon tetrachloride, tetrachlorethylene, oil of chenopodium, santonin, thymol, beta-naphthol, resorcinol derivatives, and arsenic and antimony compounds. The specific treatment for each helminthic infection such as those by various tapeworms, roundworms and flukes is given in the light of the latest experimental results. This part will be of greatest value to practitioners generally, since many helminthic infections are not confined to the tropics and the latest therapeutic advice is generally not quickly accessible.

Part III discusses protozoal diseases, especially amebiasis, leishmaniasis, trypanosomiasis and malaria. Spirilloses also are included here although more properly classified with bacterial infections. This part is also of great value because of the long and extensive experience in India with amebiasis and malaria, neither of which is confined to the tropics. The discussion is on the same plan as in that of helminthic diseases. Of especial importance is the analysis of the results of the compounds of ipecacuanha and of emetine and their various combinations with other agents; of the arsenicals stovarsol and carbarsone and of chiniofon. Less adequate is the discussion of the adjuvant effect of vioform. Experience with carbarsone for amebiasis, used with caution to avoid optical reaction, seems to be quite satisfactory.

The manifold pharmacologic and therapeutic problems that have accumulated about the quinines and their derivatives in the treatment of the malaras are amply presented. The reader will find here the latest information on quinines, on totaquina, the combination of the alkaloids of several species of Cinchona, and on plasmochin and atabrine, two synthetic compounds evolved by using the structural formula of methylene blue as a starting point. Plasmochin has not entirely replaced quinine, since it is destructive only to the parasites in the sexual phases, the so-called crescents, thus rendering the patient noninfective to the mosquito. It still leaves him subject to attacks of malaria, because it does not destroy the asexual forms in the red corpuscles. These facts are obscured in the book by an error (p. 602, line 11) in which the word "plasmodium" occurs in place of "plasmochin." To supplement this drug, another synthetic compound, atabrine, has been produced which is lethal to the asexual stages. This drug has a low toxicity, with a wide margin between the effective therapeutic dose and the toxic dose. The combination of the two drugs affords an effective

tive treatment against both types of parasitic infection by the malarial parasite. Atabrine has attained a great reputation as an effective remedy in preventing relapses in all species of human malaria.

The author adheres to the view that curative treatment, aimed at eradication of the infection, is advisable as a public health measure in territories in which malaria is infrequent and immunities are not readily maintained, and that clinical treatment only, merely to check the disease, be given in regions of a high malarial index.

Part IV discusses bacterial and virus diseases and part V reviews the remedies for miscellaneous tropical diseases, including the bites of poisonous animals and drug addiction. Part VI discusses the omnipresent skin diseases. This is followed by a dictionary of diagnosis and treatment of tropical diseases, an appendix of recent work, and a large list of useful tables. This book has much useful information in it.

The Public Health Program. Under Title VI of the Social Security Act. Supplement No. 126. U. S. Treasury Department, Public Health Service. Paper. Price, 5 cents. Pp. 23. Washington, D. C.: Supt. of Doc., Government Printing Office, 1937.

The purpose of the grants to the states is to strengthen state and territorial health departments and thereby to aid in the development of district, county and city health services and in the training of health department personnel. The provision of medical care, other than that involved in immunization for the prevention of communicable diseases and the treatment of venereal diseases to render cases noninfectious, is not contemplated under the provisions of the act. The objective is not to establish federal jurisdiction over health work within the states but to aid the states in the development and expansion of their own state and local health services. No standard pattern of organization or administrative practice is set up. Since the most important single factor in the success of a public health program is the fitness of those who administer it, an undisturbed tenure of office for competent persons is essential. To secure this competence, all public health workers should eventually receive at least one full year of special training. Extensive research plans in widely separated fields are now being conducted and it is expected that these will be expanded.

Bones: A Study of the Development and Structure of the Vertebrate Skeleton. By P. D. F. Murray, M.A., D.Sc. Cloth. Price, \$2.50. Pp. 203, with 45 illustrations. New York: Macmillan Company; Cambridge: University Press, 1936.

The author discusses briefly certain aspects of the development of the skeleton, especially the relation between the structures seen and the morphogenic factors. The chief value of the book lies in the first four chapters, which deal with embryonic and postembryonic development and with the structure of the normal and modified bony skeleton considered in relation to the function it subserves. The author discusses the primary development of the skeleton, the development of the bony skeleton, functional changes in the forms of bones, mechanical structure of bones, mechanical structure of cartilage and the mechanism of bony adaptation. There is an interesting description of the development of torsions in bones.

Bone structure is to a large degree determined, directly or indirectly, by reaction to the mechanical forces which it is the function of bone to resist. Nevertheless it will have become clear from the facts presented that the time is past when it was possible to describe the whole long and complex story of skeletogenesis in terms of the effects of mechanical stresses, whether of extrinsic and functional origin or arising in direct consequence of the developmental process itself. The form of the cartilaginous model is produced, at least in the case of the larger shafted elements, under theegis of the growth pattern intrinsic from a very early stage within each element. The bony skeleton of the adult shows both in its normal structure and after modification so close a relation to mechanical needs and so great a power of apparently adaptive change that its mechanically suitable nature cannot be doubted. The harmony with functional demands is traceable at all levels of its structure; in the shape of the whole bone, in its division into compact and cancellous bone, in the arrangement of the osteones of the first and of the trabeculae of the second, in the structure

of individual osteones and other lamellar systems, and finally in the intimate composition of the substance bone itself. Every bone structure is a compromise, and no compromise is perfect. The trajectorial theory in its original and most rigid form played a useful part in calling attention to the relation which obviously exists between bony structures and patterns of stress; but, like many theories, it went too far when it claimed all power for its own particular factor and neglected all others.

The position taken in this work is not that of the orthodox trajectorial theory. That theory regards the trabeculae of bone as embodying trajectories in a body of the same form as the bone, stressed in the same way, and of homogeneous composition. The trabeculae are thought of as drawn in such an ideal and hypothetical foundation, and the theory is intimately bound up with the existence of orthogonal structures in which all the trabeculae must cross one another at right angles, a state of affairs which, as stated in an earlier section, is not always found in nature. The view here expressed assumes no such relationship to an ideal homogeneous body, is not affected by the decidedly anisotropic structure of bone, and is compatible with the absence of orthogonal structure.

The Home Treatment of Spastic Paralysis Written in a Simple, Practical Way with Many Detailed Drawings. By Percy Merritt Girard, M.D., F.A.C.S., Chief of Orthopedic Service, Parkland Hospital. Foreword by Earl R. Carlson, B.A., M.S., M.D., Director of Department of Rehabilitation of Motor Disorders, New York Neurological Institute. Cloth. Price, \$2. Pp. 130, with 77 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1937.

This book is designed to help parents of spastic children. It is written for the layman and does not pretend to be a substitute for a doctor's advice and supervision. There is an interesting and instructive foreword by Dr. Carlson, himself a victim of this lesion. The author presents the results of his experience in the treatment of 875 cases of spastic paralysis. He has selected from a large number of exercises those which are most useful in home execution. No elaborate equipment is necessary. He gives the essential facts with regard to spastic paralysis, the location and mechanics of the paralysis, most of the common causes, and recognition of early signs of the condition. He believes that the primary objectives are prevention or correction of deformities and teaching of relaxation and coordination. These are obtained through physical therapy, occupational therapy, the proper selection of toys, and surgery. Dr. Girard brings out the principle of educating reciprocal movements in the treatment of spastic paralysis as well as the principle of muscle reeducation in which only the weaker group is exercised. In other words, it is a matter of coordination rather than muscle weakness. The list of games and toys that make use of both hands rather than emphasizing the use of only the affected arm was well chosen. Practical suggestions are made for the moderately spastic child. Heretofore, books had little material concerning the child who was mildly involved. The book is written in a simple, practical manner and contains a large number of detailed line drawings. It is one of the finest books of its kind and should be in the library of every orthopedic surgeon and every pediatrician and in every home where there is a patient with spastic paralysis.

The Physiology and Pharmacology of the Pituitary Body. By H. B. Van Dyke, Professor of Pharmacology, Peiping Union Medical College, Peiping, China. The University of Chicago Monographs in Medicine. Cloth. Price, \$4.50. Pp. 577, with 55 illustrations. Chicago: University of Chicago Press, 1936.

At a time when authors and publishers vie with one another in their attempts to get new tomes on the organs of internal secretion before the medical public, the great majority of which are half-baked compilations of uncritical reports, the appearance of a really competent review in any phase of endocrinology is an event of more than passing importance. Dr. Van Dyke has reviewed some 5,000 publications on the hypophysis in the preparation of this book; of these, 3,000 were selected for inclusion in the excellent bibliography, which requires nearly 180 pages. A vast amount of information and pseudo-information has been carefully sifted and the conclusions set down concisely and clearly. Not the least of the author's contributions consists in defining the limits of known fact and in pointing out the many deficiencies in our knowledge of the pituitary gland and its functions. The healthy skepticism that pervades

this book will help to provide an urgently needed antidote to much of the nonsense currently believed about this important organ. Among the subjects covered are the comparative anatomy of the pituitary, effects of hypophysectomy, growth-promoting principle, gonadotropic substances, lactogenic principle, thyrotropic factor, interrelations with other glands, and the effects of extracts on the function of various other organs and on the metabolism of various substances. A useful appendix containing scientific and commercial names of glandular principles and preparations is included in the book; this is one of the most extensive lists of this type available, but it is unfortunately far from complete. Format, typography and illustrations are all excellent.

The Diagnosis and Treatment of Arthritis. By Russell L. Cecil, M.D., Sc.D., Professor of Clinical Medicine, Cornell University. Henry A. Christian, M.D., Sc.D., LL.D., General Editor of the Series. (Reprinted from Oxford Monographs on Diagnosis and Treatment.) Cloth. Price, \$4.75. Pp. 263, with 17 illustrations. New York: Oxford University Press, 1936.

The purpose of the author is to bring to the practicing physician a knowledge of the most approved methods in the diagnosis and treatment of arthritis. This reprint from the Oxford monographic series on Diagnosis and Treatment should have appeared as a separate monograph six or seven years ago and at present has not been adequately revised. The author discusses classification of rheumatic fever and various etiologic forms, such as gonococcal, suppurative, allergic, intermittent and traumatic arthritis. He divides acute arthritis into infectious, septic and noninfectious. The first group includes rheumatic fever. The second group includes gonococcal, pneumococcal, suppurative and other less common forms of acute bacterial infection of the joints. Under the third group, non-infectious, there are intermittent hydrarthrosis and allergic and traumatic arthritis. The author believes that there is no disease in the whole field of medicine in which purely symptomatic treatment leads to more barren results. He considers the crucial point in any case of acute or chronic arthritis is to determine whether it is infectious or noninfectious in character. The book is a clear exposition of the subject.

La ponction de la rate. Par P. Émile-Well, médecin des hôpitaux, P. Isch-Wall, assistant à l'Hôpital Tenon, et Suzanne Perlès, chef de laboratoire à l'Hôpital Tenon. Paper. Price, 35 francs. Pp. 148, with 23 illustrations. Paris: Masson & Cie, 1936.

The various procedures habitually employed in clinical medicine in studying splenic enlargement and tumors of the left hypochondrium have sometimes yielded meager information. This monograph presents the results of what contribution splenic puncture makes to the understanding of this subject. While the method of splenic puncture is not a new procedure, the revival of its use in clinical medicine was coincident with the keen interest and recent progress in the diseases of the blood forming system. The authors review the historical background of the procedure. Its use for the most part was confined to research studies. In clinical medicine it was used mainly for the study of parasitic diseases. Its restricted use was based on fear of accidents. The authors stress the necessity of the systematic use of this procedure and caution against carelessness in the technic. By virtue of their use of the procedure in this manner they now feel qualified to discuss the morphologic pictures obtained by means of splenic puncture in various conditions.

The monograph considers the reactions of the spleen as follows:

I. Splenomegalies associated with a reaction of blood series: (a) lymphatic reaction; (b) myeloid reaction; (c) erythroblastic reaction; (d) megakaryocytic reaction; (e) leukoblastic or embryonic reaction.

II. Splenomegalies associated with a macrophagic reaction (infections and parasitic infestations).

III. Splenomegaly associated with tumors.

Normal and abnormal splenograms are presented in tabular form and in black and white drawings, which are well executed with the exception of the Gaucher cell. A small and inadequate chapter is devoted to sternal puncture, with no illustrations. Why it was included in a monograph devoted to splenic puncture was not indicated. It neither contributes nor detracts. The technic and cytology of splenic puncture are well presented

but data on splenic puncture in infants and children are almost neglected. The work reflects a long clinical use of the procedure and the authors present data that should prove valuable to any one doing hematologic work extensively. The material is divided into three parts. In the first part of the monograph the authors describe the technic of splenic puncture and the precautions and contraindications, the normal splenogram and a description of the cells encountered, and the pathologic splenogram and a description of the abnormal cellular elements. Part II is concerned with information obtained by splenic puncture on the nature of the splenomegalies, and part III discusses puncture of tumors in the left hypochondrium and sternal puncture. The bibliography is not extensive or complete but is adequate for the material presented. Information available on the systematic use of splenic puncture has been meager, and this monograph fulfils a definite purpose in supplying these data.

Essentials of Electrocardiography for the Student and Practitioner of Medicine. By Richard Ashman, Ph.D., Professor of Physiology, the Louisiana State University Medical Center, and Edgar Hull, M.D., Assistant Professor of Medicine, the Louisiana State University, New Orleans. Cloth. Price, \$3.50. Pp. 212, with 101 illustrations. New York: Macmillan Company, 1937.

This reflects for the most part the personal experience of the authors, the basis for their criteria of the normal being a series of 100 cases. These closely agree with the results of many workers that have been used in establishing the criteria for graphic interpretation now employed. "Incorporated in the text is a considerable mass of original material." These observations are valuable but might better have been reported elsewhere. Basic physiology is well presented. The last two chapters dealing with disturbances of the cardiac mechanism could have been advantageously introduced earlier, emphasis still being rightly placed on abnormalities indicating myocardial disease. The views regarding bundle branch block and chest leads are those of F. N. Wilson, as is the technic described for obtaining chest leads. Opinions at variance with the views of others are relatively few. Minor variations from standard terminology are noted. The index is good. This is an excellent presentation of a wealth of valuable observations. The student and the practitioner will find the book most useful as a supplement to one of the other more comprehensive textbooks employing "the 'classical' approach" in presentation.

Principles of Pharmacy. By Henry V. Arny, Ph.M., Ph.D., Dean and Professor of Chemistry in the College of Pharmacy of Columbia University. With the collaboration of Robert P. Fischell, B.Sc., Ph.M., Ph.D., Secretary and Chief Chemist, Board of Pharmacy, State of New Jersey. Fourth edition. Cloth. Price, \$8. Pp. 1,139, with 294 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

This book is primarily written for students of pharmacy, but it contains considerable material with which the physician should be familiar. The volume consists of seven parts: (1) pharmaceutical processes, (2) galenical preparations of the pharmacopeia and those unofficial that are worthy of notice, (3) inorganic chemistry, (4) organic chemistry, (5) chemical testing and analytic methods of the pharmacopeia, and (6) the dispensing of prescriptions. The present edition is based on the Pharmacopeia XI and the National Formulary VI. It is unfortunate that neither New and Nonofficial Remedies nor the recent advances in the chemistry of glandular products are mentioned.

Esplenomegalias crónicas no leucémicas: Indicaciones médicas de la esplenectomía. Por el Dr. Rodolfo Armas Cruz, profesor extraordinario de patología médica. Paper. Price, \$4. Pp. 526, with 29 illustrations. Santiago de Chile: Central Pacífico de Publicaciones, 1936.

This voluminous essay should be of great value for those interested in certain phases of knowledge pertaining to the spleen. The work comprises more than could be expected from the title and is divided into three parts. The first gives a thorough description of the embryology, anatomy, physiology and methods employed in the study of the functions of the reticulo-endothelial system; one chapter of this first part is devoted to the physiology of the spleen. The second part describes methods of investigation of the spleen function; one section treats of hypersplenism; the author offers a definition of this condition and describes several varieties of it and the diagnosis. The third part carries the title of the book and is subdivided into two sections; one deals with hemolytic jaundice

and the other with chronic splenic anemia. Purely surgical conditions, such as abscess, tumor and cyst of the spleen are beyond the scope of the book; the author confines his discussion to nonleukemic splenomegalies in which splenectomy is indicated. His conclusions are based on the correlation of clinical, hematologic and anatomic observations in numerous cases. A large number of charts, photomicrographs and case histories demonstrate the great personal experience of the author. Whether his subdivision of chronic splenomegalies of nonleukemic origin is preferable to Aubertin's classification is a matter of personal view; this is not the place to enter into a polemical discussion. It is questionable from the didactic, diagnostic and therapeutic points of view whether one can approach the problem of nonleukemic splenomegalies without taking into consideration such conditions as polycythemia, essential thrombopenia, aleukemic lymphadenosis or myelosis, multiple chloromas of aleukemic origin, and bronze diabetes. A unanimity of opinions cannot be expected with regard to such obscure problems as are offered by pathologic conditions of the spleen. Notwithstanding the foregoing remarks, the scholarly work merits a high place among monographs on the spleen.

La vésicule biliaire et ses voies d'excrétion. Anatomie—Physiologie—Sémiologie—Pathologie—Thérapeutique. Par M. Chiray, professeur agrégé à la Faculté de médecine de Paris, et I. Pavei, maître de conférences à la Faculté de médecine de Bucarest. Avec un exposé de radiologie vésiculaire. Par A. Lomon, électro-radiologiste des hôpitaux de Paris. Second edition. Paper. Price, 120 francs. Pp. 863, with 203 illustrations. Paris: Masson & Cie, 1936.

The first edition of this monograph was published in 1926. The first part of the new edition covers the details of the anatomy, histology and physiology of the gallbladder and bile ducts. From this point on the author takes up successively methods of physical examination and duodenal drainage and discusses in detail the significance of the types of bile present. There is a long chapter dealing with radiologic examination of the gallbladder, including choledochographic studies. Various types of lesions of the gallbladder are discussed in detail and several reproductions of colored photographs show various types of diseases of the gallbladder and various types of gallstones. There is a good chapter on functional abnormalities of the biliary tract and a chapter on carcinoma of the gallbladder. It would appear, however, that too brief a portion of the book is given to the matter of therapy, only thirty-eight pages being given to the surgical treatment. This chapter on surgical treatment contains too few illustrations. Except for this, each chapter covers the subject matter fully, and the whole monograph furnishes a detailed presentation of the subject of diseases of the gallbladder and bile ducts. There is a detailed bibliography.

A Woman Surgeon: The Life and Work of Rosalie Slaughter Morton. Cloth. Price, \$3. Pp. 399, with one illustration. New York: Frederick A. Stokes Company, 1937.

Good autobiographies are greatly appreciated. That of the distinguished woman surgeon Rosalie Slaughter Morton is a gem. It is a deeply moving story of the evolution of one of the most prominent pioneer women surgeons in the United States. The true tale is full of thrilling, touching or amusing stories. Personal reminiscences are interspersed with sketches of the humanitarian work of the author among the lower strata of various nations; extensive travel and exciting personal adventures are described with a narrative technic rarely found in modern biography. The entertaining book not only provides delightful reading material but offers a picture of an exemplary life, worthy of imitation.

Fifteenth Hospital Yearbook. 1937 Hospital Purchasing File: Directory of Products, Manufacturers' Catalogs, Purchasing and Other Reference Data. Cloth. Price, \$2.50. Pp. 801, with illustrations. Chicago: Modern Hospital Publishing Company, Inc., 1937.

This book contains a discussion of the methods and principles of hospital purchasing, organizing the hospital storeroom, guides and check lists for the purchase of food, equipment and supplies. It presents standards for hospital equipment and supplies as well as chapters on business administration, public aspects of hospital work, minimum hospital standards of various agencies, a glossary of hospital terms, and a directory of hospital and medical associations and national agencies serving hospital and allied fields.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Diphtheria Mistakenly Diagnosed as Tonsillitis.—The plaintiff, "a believer in the profession of naturopathy," engaged the defendant, a naturopath, to treat his infant son for a condition which was diagnosed, it was alleged, as tonsillitis. The child had diphtheria, from which he died. Thereafter the plaintiff sued the defendant, and the trial court gave him judgment for \$1,400. The defendant appealed to the Supreme Court of North Carolina.

The plaintiff's belief in naturopathy, said the court, would not prevent his recovering damages for the death of his son if he proved that the death of the child proximately resulted from the negligence and unskilful treatment of the defendant according to the method he held himself out to know and practice. The defendant was a graduate of the American School of Naturopathy. He had practiced in New York, apparently without a license, and in Florida, where he had obtained a certificate to practice. He had not obtained a license to practice in North Carolina. Nevertheless, he had been engaged in practice in that state and had been previously employed by the plaintiff to treat other members of his family on several occasions. In determining liability in a civil action for damages on the ground of negligence, the court said, the defendant was not required to possess the highest technical skill or the wide scientific knowledge and learning of the well recognized schools of medicine and surgery, or to exercise the utmost degree of care. He was required to exercise that degree of care, knowledge and skill ordinarily possessed by members of his school of practice. Although the defendant held himself out, and the plaintiff, on behalf of his infant son, consulted him, as a practitioner of naturopathy and not as a regular physician, the defendant claimed, the court said, to possess the skill requisite for diagnosis and treatment of disease, and in the performance of what he undertook to do he must be held to the degree of skill and care which he claimed to possess. A person who undertakes to treat the sick and holds himself out as competent to administer a certain kind or character of treatment undertakes to bring to his employment in each case a fair, reasonable and competent degree of skill and reasonable care and diligence in the exercise of his skill and in the application of his knowledge. He undertakes to exert his best judgment and give reasonable attention to the progress of the treatment he prescribes. He is answerable in damages for injuries proximately resulting from want of that degree of knowledge and skill ordinarily possessed by those of his system or method of practice, or from failure to exercise due care and diligence or to use his best judgment in the treatment of the case.

The defendant offered two witnesses, both naturopaths, to show that the treatment of the plaintiff's son, as testified by the defendant, was in keeping with the practice of naturopathy generally, and conformed to the teachings and practices of naturopathy in diseases of this kind. On objection by the plaintiff, this evidence was excluded, the court holding "as a matter of law that the witness was not an expert witness." The witnesses were graduate naturopaths and were licensed to practice naturopathy, respectively, in Virginia and in Florida. The trial court erred, said the Supreme Court, in ruling out this evidence. An "expert," the court said, has been defined as "one who is skilled in any particular art, trade or profession, being possessed of peculiar knowledge concerning the same." The term implies both knowledge from study and practical experience in the art or profession. The common law does not require that an expert witness shall be a person duly licensed to practice medicine. While the competence of a witness to testify as an expert is a question primarily addressed to the discretion of the trial court and its decision is ordinarily conclusive, this rule is subject to the qualification that, when the preliminary question of the competence of the witness is made to turn on a matter of law, it is subject to review. The witnesses should have been permitted to testify.

The fact that the defendant was engaged in treating patients in North Carolina without having obtained a license so to do

was not evidence, in the opinion of the court, of negligence in the treating of the plaintiff's son. The question was not whether he was licensed or not but whether he exercised proper care in the treatment of the patient. If the defendant engaged in treating diseases in violation of the law, he was liable to indictment and on conviction to suffer the prescribed penalties. In a civil action, however, bottomed on the law of negligence, the failure to possess a state license was not material on the question of due care.

For the error committed by the trial court in refusing to permit the defendant's expert witnesses to testify, the Supreme Court reversed the judgment for the plaintiff and remanded the case for a new trial.—*Hardy v. Dahl* (N. C.), 187 S. E. 788.

Charitable Hospitals: Liability When Profit Results from Operation of Hospital.—The plaintiff was a pay patient in the defendant hospital, an institution organized not for profit. A nurse negligently placed a hot water bottle against the plaintiff's leg in such a manner as to cause a third degree burn. Thereafter, the plaintiff instituted suit against the hospital. The trial court, after the plaintiff had finished the presentation of his evidence, directed the jury to return a verdict in the defendant's favor. The plaintiff appealed to the district court of appeal, second district, division 2, California.

The by-laws of the defendant hospital corporation stated that it was organized not for profit. The evidence showed, however, that the hospital operated for profit a number of departments to which the public had access, such as a pharmacy, lunch counter and soda fountain, including magazines and toilet articles; that in 1935, the year in which the plaintiff was injured, the hospital realized a profit of \$62,767; and that it cared for 7,672 patients, of whom only 191 were free patients. The evidence did not indicate that the plaintiff was aware of the charitable status of the hospital or that it claimed to be free from liability for negligence on the part of its employees. The general rule, said the court, applicable to persons receiving benefits from charitable institutions in California was well stated in *Stewart v. California Medical, etc., Ass'n*, 178 Calif. 418, 176 P. 46. In that case the court said:

The true doctrine amounts to this: That where one accepts the benefit of a public or of a private charity, he exempts by implied contract the benefactor from liability for the negligence of the servants in administering the charity, if the benefactor has used due care in the selection of those servants. . . . The character of the institution is to be determined, not alone by the powers of the corporation as defined in its charter, but also by the manner of conducting the hospital. . . . In the instant case, we hold that the trial court was required to look, not only to the defendant's articles of incorporation and by-laws to determine the character of the hospital conducted by it, but also to the method of transacting the business of the corporation. Its finding that the hospital was in fact operated for profit is supported by the evidence, and we see no good reason for exempting the defendant from the liability incurred by other hospitals conducted for profit.

In the present case, said the district court of appeal, the trial court erred in refusing to submit to the jury the issue of plaintiff's claim that the hospital was in fact conducted for profit. The trial court should also have submitted to the jury under appropriate instructions the question of plaintiff's knowledge of defendant's claim to nonliability on account of its charitable activities. The court expressed its disinclination to hold that one who, without knowledge that a hospital claims to be a charitable institution and therefore exempt from liability, applies for admission and is received as a patient, paying the regular rates at which the hospital derives a profit, is without redress for injuries occasioned by negligence on the part of the employees of the hospital on the theory that the patient is accepting the benefits of charity from a benefactor.

The plaintiff further contended that he presented sufficient proof that defendant did not use due care in the selection of its employees to have that issue submitted to the jury. With this contention, the district court of appeal agreed. The director of the hospital's nursing service testified that the nurse causing the injury had submitted a written application for employment, but that the references therein had never been checked and that no inquiry was made of the bureau of nurses of the state department of health with respect to her standing. The chief of the bureau of registration of nurses of the state testified that the nurse had filed an application for registration as a nurse in California but that her registration was rejected on the ground that she was ineligible. This evidence, in the opinion of the

court, was sufficient to call for the submission to the jury of the question whether the defendant had used due care in employing the nurse who attended the plaintiff.

For the reasons stated, the judgment of the trial court for the hospital was reversed.—*England v. Hospital of the Good Samaritan (Calif.)*, 61 P. (2d) 48.

Contracts: Validity of Agreements in Restraint of Professional Practice.—The plaintiffs, practicing physicians, conducted a medical center and clinic in Yates County, N. Y., under the name of the Foster-Hatch Medical Group. They entered into a contract of employment with the defendant, a physician, wherein he agreed not to engage in or practice his profession as a physician in the county of Yates except while in the employment or associated with the plaintiffs, without the written consent of the plaintiffs. If he violated this agreement, he was to pay the plaintiffs the sum of \$10,000 as liquidated damages. After about two and one-half years of service with the plaintiffs, the defendant severed relationship with them and, without their consent, continued to practice in Yates County. The plaintiffs therefore instituted the present action to enjoin the defendant from practicing in violation of his agreement. The trial court dismissed the complaint, and the plaintiffs appealed to the supreme court, appellate division, New York.

Agreements, said the court, imposing restraints on the right of an employee to engage in competitive service after the termination of the contract of service are analogous to, and governed by, the same rules applicable to restrictive covenants in the sales of business and good will. It is manifest that a physician employed as an assistant to another must in the course of his duties become acquainted with the patients of his employer and acquire their confidence and good will. The contract in this case was drawn to provide against the business and good will of the plaintiffs being lost to them in case of the defendant's locating in Yates County after the severance of the employment. The defendant's establishing himself in Yates County for the practice of medicine was a deliberate choice on his part to disregard his agreement not to compete with his former employers. In such circumstances, a court of equity will extend the arm of injunction. Agreements permanently to refrain from the practice of a profession in defined localities have been sustained in many cases. The stipulation in the contract for liquidated damages in case of violation of the agreement does not oust a court of equity from jurisdiction to entertain an application for injunctive relief. The order of the trial court dismissing the complaint was therefore reversed. Thereafter, the defendant appealed to the Court of Appeals of New York which, without a written opinion, affirmed the order of the appellate division.—*Foster v. White (N. Y.)*, 290 N. Y. S. 394; 7 N. E. 710.

Malpractice: Mistake in Diagnosis; Failure to Make a Wassermann Test.—The plaintiff consulted the defendant, a physician, because of a swelling of his left knee. The defendant made a diagnosis of sarcoma and applied a course of treatment that did not improve the condition. On the contrary, the skin over the swelling broke open and a cauliflower mass developed, which increased in size and discharged large quantities of pus. Another physician was consulted, who sent the plaintiff to a hospital, where roentgenograms and a Wassermann test were made and tissue from the diseased area was examined microscopically. Chiefly on the basis of a positive Wassermann reaction, the lesion at the knee was attributed to syphilis and diagnosed not as sarcoma but as a gumma. Anti-syphilitic treatment was administered, followed by immediate improvement. The plaintiff continued, however, to suffer pain and his left leg remained crippled and stiffened. Subsequently the plaintiff sued the defendant, and the jury returned a verdict for the plaintiff for \$25,000. The court thought the amount of the verdict excessive and entered judgment for \$7,000. The defendant appealed to the Supreme Court of Michigan, where, because of an erroneous instruction given by the trial court, the judgment was reversed and the case remanded for a new trial. *Fortner v. Koch (Mich.)*, 261 N. W. 762; abstr. THE JOURNAL, Feb. 22, 1936, page 651.

The second trial resulted in a judgment for the plaintiff for \$5,500, from which the defendant appealed to the Supreme Court of Michigan. One of the contentions made on the second appeal

was that, in the absence of any claim in the declaration that the defendant should have made a Wassermann test, the trial court erred in admitting evidence which tended to show that he failed to make the test. The testimony, said the Supreme Court, showed that the proper method of diagnosis in the case was not only to take the history of the patient but also to have a roentgenogram made, a blood test taken and a biopsy made. Failure of the declaration to state that it was the duty of the defendant to have the Wassermann test made was not fatal, in the opinion of the court. The defendant as a physician knew, or should have known, that this was one of the steps in arriving at a proper diagnosis in the case. The declaration, said the court, was sufficient. Finding no error, the judgment of the trial court was affirmed.—*Fortner v. Koch (Mich.)*, 269 N. W. 222.

Malpractice: Surgical Forceps Left in Patient; Statute of Limitations.—One of the defendants, the surgeon in charge of the Harlan Hospital Association, Inc., performed an abdominal operation on the plaintiff's wife in February 1932. Two years and a half after the operation the patient evacuated from her rectum one half of a surgeon's forceps. A roentgenogram revealed that the other half of the forceps was still in her abdomen and a second operation was performed to remove it. Thereafter the husband sued the hospital and the surgeon to recover damages for the loss of the society and services of his wife and to recover the medical expense incurred by reason of the alleged negligence of the defendants. The trial court sustained a defense that the suit was barred by the statute of limitations, and the plaintiff appealed to the Court of Appeals of Kentucky.

In Kentucky, said the court, an action brought by a husband for injuries to his wife must be commenced within one year after the cause of action accrues, and the cause of action accrues at the time of the injury resulting in the loss of services or consortium. The plaintiff argued, however, that the cause of action did not accrue until it became known by him and his wife, or could have been known by the exercise of ordinary care, that the forceps were left in the abdomen of his wife. But, said the court, a cause of action accrues when a party has the right and capacity to sue, and his right of action is not suspended until such a time as he ascertains that he has a cause of action. Here the injury was the result of negligence in the original operation, and the action is predicated on that negligence. In answer to the plaintiff's contention that the cause of action was fraudulently concealed by the defendant, the court said that, the intent being controlling, fraudulent concealment is necessarily based on knowledge and not on what may be discovered by the exercise of ordinary care. The allegation, therefore, that the defendants knew, or by the exercise of ordinary care could have known, that the forceps were left in the patient's abdomen was not sufficient to show fraudulent concealment. According to the petition, the patient was injured when the first operation was performed, and the plaintiff was then deprived of her services and society, and the only thing that she or the plaintiff did not know was the means whereby the injury was inflicted. Clearly, the fact that she or he was not informed as to the way or means did not have the effect of suspending the one-year statute of limitations. The time of the injury itself is the controlling fact, and not the means by which the injury was inflicted. The judgment of the trial court for the defendants was therefore affirmed.—*Carter v. Harlan Hospital Ass'n (Ky.)*, 97 S. W. (2d) 9.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Inguinal Granuloma Differentiated from Lymphogranuloma.—Reaves believes that inguinal granuloma and inguinal lymphogranuloma tend to affect unclean persons; this tendency, combined with the chronicity of the diseases, renders their cure difficult. The existence of other diseases with similar lesions adds to the problem. In one of his cases of inguinal granuloma the disease persisted for twenty-three years before an ultimate cure was established, and at no time was there involvement of the lymph nodes. Inguinal lymphogranuloma, a disease of the lymph nodes caused by a filtrable virus which can be transmitted to several of the lower animals, is of venereal origin and is frequently classified as the fourth venereal disease. Frei and Hoffman distinguish two periods of incubation. One is from the time of the infecting coitus to the appearance of the primary lesion; the other is from the time of the infecting coitus to the onset of the swelling of the inguinal node. The second period varies from ten days to a maximum of six weeks, with an average duration of from two to three weeks. The initial lesion is so mild that it often goes unnoticed by the patient and is rarely observed by the physician. It may be present as a nodular, papular or herpetiform lesion, or it may appear as an intra-urethral erosion simulating gonorrhea.

Oophorectomy and Carcinoma of the Breast.—Herrell finds that of 1,906 patients with carcinoma of the breast only twenty-eight had undergone complete oophorectomy before mammary carcinoma was found. If those cases are eliminated in which oophorectomy was performed so short a time before the diagnosis of carcinoma of the breast that the procedure could hardly be said to influence the development of the disease, that is, less than three years before, the incidence of castration or complete oophorectomy falls to the low point of 1 per cent. The incidence of complete oophorectomy or castration was approximately ten times as great among the 1,011 non-cancer bearing women as in the group of women with carcinoma of

the breast. The accumulating evidence is that ovarian secretions do in some way play a definite part in the development of mammary tumors, not only in mice but also, as these studies strongly suggest, in women. The genetic factor is perhaps the most baffling aspect of the problem as it bears on the human being and indeed, in that bearing, seems beyond control. Yet, the ovarian functions are factors in the internal environment of the individual and, as these results indicate, probably play a definite part in the incidence of mammary cancer; these factors are, furthermore, controllable. The study supplies excellent indication that the ovarian rôle may be a definite one in human beings, as it is in animals whose genetic factors can be more or less controlled at will. In recent years castration by radiation combined with surgical operation has been regarded with considerable interest by some in the treatment of mammary carcinoma. The time to combat cancer is not in the inoperable stage but, if possible, before it develops, and this can be accomplished only when more is known concerning the factors which underlie the genesis of the disease.

Electrodesiccation of Epithelioma of Lip.—Morrow and his co-workers have treated epithelioma of the lip by means of curettage followed by electrodesiccation for the last five years. Twenty-three of fifty-four patients treated in the clinic and thirty-one of eighty-five of those treated at the office could not be traced. Of the fifty-four office patients traced, forty-three were well and had no evidence of disease from six months to five years after treatment. Of the twenty-six clinic patients traced, twenty-three were apparently cured. A number of the patients classified as well have had recurrences which responded to the same form of treatment. Others have had new lesions on a different portion of the lip. The clinical and cosmetic results are apparently as good as those which follow surgical therapy. This method of treatment is recommended because of its effectiveness, the ease with which it can be applied and its small expense to the patient.

Diet and Cutaneous Infection.—Pillsbury and Sternberg observed the reaction of dogs to the intradermal injection of broth suspensions of living staphylococci and streptococci. The dogs were divided into groups receiving low carbohydrate, high carbohydrate or high fat diets or fasting. The cutaneous infections were in general definitely more severe in animals on a high carbohydrate intake than in those on a low carbohydrate or a high fat diet and in fasting dogs. Representative determinations of the sugar content of the blood indicated that no significant variations from normal occurred. In six of eight animals given a high fat diet, evidence of acidosis developed; the infections noted in these animals with one exception were mild. The glycogen content of the skin showed but slight response to variations in the diet, and there was no evidence indicating that it was of any great importance in the metabolism of the skin or in the organism as a whole.

Muscular Exercise and Blood Sugar.—The Smiths determined the effect of exercise on glycosuria and glycemia in twelve cases of diabetes mellitus treated with insulin, in four of diabetes mellitus treated without insulin, in three of renal glycosuria, in two of hypotension, in one patient with glycosuria of pregnancy, in one obese patient, in one with epilepsy and in three normal individuals. Exercise of sufficient intensity and duration, they found, will lower the postprandial blood sugar in controlled diabetes mellitus treated with or without insulin, in renal glycosuria, in hypotension, in obesity and in normal subjects. Exercise in the uncontrolled case of diabetes, in the amounts performed in these experiments, does not have a noticeable effect in lowering the postprandial blood sugar. Exercise seems to have the greatest effect in lowering the postprandial blood sugar in the irregularly controlled case of diabetes, when measured by the difference in the resting and exercising blood sugar levels at the end of exercise, and by the resulting clinical symptoms at this time. Exercise of the intensity performed in these experiments is not sufficient to lower the blood sugar below normal fasting levels in nondiabetic subjects.

Thyroid and Parathyroid in Calcium and Phosphorus Metabolism.—Cope and Donaldson studied the calcium and phosphorus metabolism in a patient with recurrent thyrotoxicosis and postoperative parathyroid tetany. When the metabolic rate was maintained within normal limits with iodine medication, the calcium and phosphorus ratios were characteristic of parathyroid tetany. When hyperthyroidism was present, a marked increase in the negative balance of calcium and phosphorus beyond normal limits was found, even though signs of diminished parathyroid activity continued. Increased thyroid activity was followed by a rise of the subnormal blood serum calcium level toward normal and a decrease in the signs of tetany. The reverse occurred with a decrease in thyroid function. An acute infection of the upper part of the respiratory tract was associated with an increase in the amount of clinical tetany and also with a spontaneous remission of the thyrotoxicosis. Because of the probably continued subnormal activity of the parathyroid it is concluded that the changes of calcium and phosphorus metabolism were due to the changes in thyroid

function. The relation of the parathyroid, thyroid, anterior pituitary and adrenal cortical glands in calcium metabolism is discussed.

Renal Physiology in Lobar Pneumonia.—Farr and Abernethy observed twenty-eight patients, admitted consecutively to the Rockefeller Institute Hospital for treatment of pneumonia, for periods up to six months. On admission a urea clearance test was done; the following day a sediment count was performed. Urea clearances were repeated every three days until crisis and on the day of crisis. During the acute illness, twelve hour clearances were done. Another urea clearance was done five days after crisis and at the time of discharge. Following discharge, urea clearances were done on the patients in the outpatient clinic once a month until renal function had been normal for two months. Sediment counts were done on the first and on the sixth day after crisis. Quantitative estimations of urinary protein by the method of Shevky and Stafford were performed daily during the febrile period and as long thereafter as protein was present. Blood pressure determinations were done daily, and retinal examinations were made on each patient during the acute illness as well as in convalescence. None of the patients gave any history of pre-existing renal disease. During the febrile period the average urea clearance for eleven patients in the age group 10 to 29 years was elevated to 147 per cent of normal. The average for four patients from 30 to 39 years of age was 111.8 per cent of normal; of five patients from 40 to 49 years of age, 97.7 per cent normal, and of five patients from 50 to 65 years of age, 82.6 per cent of normal. The clearances done immediately after crisis and while the patient was still in the hospital did not show a rapid return to normal. At no time during the acute illness did any of the younger patients have a urea clearance below 110 per cent of normal. In the age group 30 to 40 years there was only moderate hyperfunction during the first ten days of the disease, but in no instance was hypofunction noted. In the age group 40 to 50 years there was no increase of the urea clearance during the acute and convalescent periods of the illness. The clearance returned to an average value for this group in about three months. In the oldest group there was no definite shift in the clearance below normal minimum, but the values during the acute illness were in general somewhat below normal average. The blood urea nitrogen in all but two of the patients at the time of admission was within normal limits. The amount of protein lost in the urine by these patients during the febrile period was negligible. The majority excreted less than 0.1 Gm. of protein daily throughout their entire hospital stay. In no instance was the number of red blood cells excreted in twelve hours greater than the normal values defined by Addis. Casts, however, were uniformly increased in number, with the hyaline type predominating. When the patients were extremely ill, the proportion of granular casts increased. In the two patients who died, the differential cast count revealed 100 per cent granular casts with a large number of casts excreted in both instances. There was no significant alteration in the blood pressure accompanying the alteration in the urea clearance. In general, the blood pressure tended to be a little below normal during the febrile period of the disease, returning to the usual normal levels during convalescence. Daily measurements of fluid intake and output were made on these patients and no deviations from the expected relations were noted. There was no relation between fluid intake and clearance, or between fluid intake and the number of observed formed elements in the urine. Sodium chloride in therapeutic doses had no demonstrable effect on the urea clearance. There was no demonstrable difference between the effects of different pneumococcus types on renal function. Nor did the early and effective use of therapeutic serums have any demonstrable effect on the renal function during the acute illness or during serum disease.

Clinical Changes Produced by Diarrhea.—Hill declares that clinical changes result from diarrhea only when the diarrhea is of a severe type. Mild types of diarrhea produce little or no evidence of illness beyond fretfulness. The symptoms produced by a severe type of diarrhea are usually described under the terms of "alimentary intoxication" or "intestinal toxemia." The clinical changes entering into the picture of alimentary intoxication are subdivided into athrepsia, anhydremia and dehydration, acidosis and toxicosis, and are discussed separately. The therapeutic indications for restitution of the clinical changes brought about by severe diarrhea are the replacement and maintenance of the fluid and mineral balance of the blood plasma and tissues of the body. Protein milk, acidified milk and raw apple are suggested as measures to be used in dietary management.

Vitamin C and Tuberculosis.—Petter administered vitamin C in a chocolate-malt-milk base. The preparation contains 50 mg. of chemically pure cevitamic acid and 7½ grains (0.5 Gm.) of dibasic calcium phosphate in two heaping teaspoonfuls, or 20 Gm. This amount was given three times daily in 7 ounces (200 cc.) of milk. The preparation as given in milk supplied 150 mg. of vitamin C daily and added 654 calories to the regular diets. Of the forty-nine adults treated, thirty showed definite improvement, in twelve there was no change, and seven were definitely worse. Twenty-one children showed improvement in weight and general condition. Elimination of cevitamic acid was found to be below normal in cases of advanced tuberculosis and was brought up to normal by feeding this vitamin in the foregoing doses.

Osteitis Fibrosa and Precocious Puberty.—Albright and his colleagues report five cases of a syndrome characterized by (1) bone lesions which have a marked tendency to be unilateral and which show osteitis fibrosa on microscopic examination, (2) brown nonelevated pigmented areas of the skin which tend to be on the same side as the bone lesions and (3) an endocrine dysfunction which in the female is associated with precocious puberty. The multiple bone cysts have a distribution suggesting a relation to nerve roots or to an embryologic defect in the myotomes. The precocity is unusual in that it does not lead to sterility or to other endocrine disturbances. Certain circumstantial evidence, especially the fact that the precocity apparently does not occur in males, suggests the hypothesis that this part of the syndrome is due to a disturbance in the follicle-stimulating hormone of the anterior pituitary. Small testes with normal secondary sex characteristics were present in the one case occurring in a male. The bone lesions consist of multiple circumscribed areas of what appears to be osteitis fibrosa with normal bone elsewhere. The term osteitis fibrosa disseminata is suggested to differentiate the condition from osteitis fibrosa generalisata (hyperparathyroidism) and osteitis fibrosa localisata (solitary bone cyst). Several cases observed elsewhere were confused with hyperparathyroidism. The bone manifestations, however, differ from hyperparathyroidism in that they are spotty rather than generalized and are not attended by changes in calcium and phosphorus metabolism. The suggestion is made that the endocrine disturbance as well as the bone lesions and pigment spots may be manifestations of an underlying neurologic disturbance or of an embryologic defect.

Trichinosis.—Hall and Collins examined 300 diaphragms from patients representing practically all parts of the United States. With these cases as a basis, they expect to be able to study the correlations of the incidence of trichinae with such data as military or civilian status, association with land and sea, high and low economic-social status, mental derangement associated with long hospitalization, and the absence of any such derangement associated with prolonged hospitalization, as well as to study correlations with sex, race and age. Their study of incidence by the use of the microscopic and digestion-Baermann technics affords an opportunity to check the value and limitations of each technic and to make a tentative estimate of the probable error in previous studies. If they take their unweighted average of approximately 12.5 per cent (on the basis of 1,778 cases reported up to the present time and the forty-one cases in their 300 diaphragms examined), a figure which for several reasons is obviously too low, it implies that one out of every eight persons in our population of 130,000,000 persons is infested with trichinae, or approximately 16,000,000 persons above the age of infancy, provided the incidence in cadavers examined gives the incidence for the general population. The United States, so far as data are available, has the greatest problem in trichinosis of any country in the world, even though the supposed incidence in some other countries is greater than it is thought to be. Meat inspection of a quality equivalent to that of the federal meat inspection system should be extended to all meat produced in the United States. The swine sanitation system should be used much more widely by hog raisers. The campaign to educate the public against the use of any raw pork, or of any pork products customarily eaten uncooked that do not originate in establishments under federal inspection, should be more intensive.

Tuberculosis and Malignant Tumors.—In 354 consecutive necropsies on individuals 1 year of age or older Moore and Neal found seventy-three instances of malignant growths and eighty-nine of active tuberculosis. In these there were twenty cases in which active tuberculosis and a malignant tumor existed concurrently. If a comparison is made between this double lesion group and the total number of cases in each of the two diseases, it is found that a malignant neoplasm also was present in 22.47 per cent of this series with active tuberculosis, while active tuberculosis was present in 27.4 per cent of those with a malignant growth. Because of the high cancer incidence in this series, 20.62 per cent, the percentage relationships are unquestionably out of proportion for the general population. Comparison reveals that the incidence of active tuberculosis and malignant tumors, each as an entity, was higher in the female than in the male, and consequently the incidence of the double lesion group was greater in the female. The incidence of the double lesion as well as that of malignant manifestation in general was appreciably higher in the white than in the Negro race. The seventy-three cases of malignant growths were found to be carcinoma fifty-three, sarcoma ten, hypernephroma four, mesothelioma two, Hodgkin's disease two, malignant glioma one, and malignant thymoma one. The concomitant occurrence of active tuberculosis and carcinoma, particularly when the patient is 35 years of age and older, in many cases is due to the breakdown of a previously existing inactive or latent tuberculous lesion rather than to a reinfection. The high incidence of association, 21.42 per cent, of active pulmonary and tracheobronchial lymph node tuberculosis with carcinoma of the esophagus and stomach is due in the majority of such cases to the activation of a latent tuberculous focus as a result of the cachexias, toxemias and malnutrition; that develop from cancers at these sites. The unaccountable rapidity and unfavorable clinical progress of many cases of cancer is due to the activation of a latent tuberculous lesion. In the reactivation of tuberculosis in elderly patients, a malignant condition is to be considered a factor in more than 20 per cent of the cases. There is almost a four times greater incidence of active tuberculosis, with a concurrent malignant neoplasm, in the age group above 35 than in that below, the respective percentages being 7.25 and 1.88.

Angina Innocens.—Bourne suggests the term angina innocens for the condition usually labeled pseudo-angina. Angina innocens is descriptive of the cardiac and at the same time the innocent nature of the pain. It is associated with no definite cardiac disease, is apparently of functional origin and has a favorable prognosis. A study of thirty-eight patients suffering from such pain, who have been under investigation for varying periods since 1929, is given. Simultaneously a study of a large number of patients complaining of the other forms of cardiac pain has served as a background, against which the present syndrome has stood out more clearly with the passage of time. Of the thirty-eight patients, twenty-two were females and sixteen males. The ages at which the syndrome manifested itself were between 12 and 65 years. In the past history two facts stand out: the high incidence of rheumatic infections and tonsillitis, and the frequency of psychologic disorders. In addition to the precordial pain the other symptoms were as follows: Marked lassitude was complained of in thirty cases, shortness of breath of a not very pronounced degree occurred in twenty-nine cases, orthopnea was found in seven cases, palpitation was complained of by twenty-nine patients, giddiness was a symptom in twenty-seven cases, faintness, without loss of consciousness, in seven, and thirteen patients gave a history of fainting. Twenty-nine patients complained of a sense of left-sided constriction. Dyspepsia was present in fourteen cases and in several appeared to be a predisposing or trigger symptom, for successful treatment of the dyspepsia generally led to considerable diminution in the severity of the cardiac pain. In no case, however, could it be said that the dyspepsia by itself was the cause of the cardiac pain. In thirty-three of thirty-eight cases the pain was felt on the left side of the chest, either over the apex of the heart or higher over the precordium. The pain of angina of effort is characteristic, and a careful history will in all cases differentiate the condition from angina innocens. If pain is complained of as occurring only during exertion, if it is related to exertion and never arises at rest or at night, it may be taken that the patient is not suffering from angina innocens but from angina of effort. The syncopal type of angina innocens may suggest an epileptic attack with a visceral aura. The onset, however, is less abrupt than that of epilepsy. Convulsions do not occur. There is no incontinence of urine. The course of the disease is unlike that of epilepsy, for there is no progressive increase in the severity of the symptoms. The patients generally show steady, if slow, improvement. It is difficult to understand how the pain of angina innocens is produced. There is quite obviously no coronary disease. The severe spasmodic type of attack may just possibly be associated with some temporary coronary spasm, but of this there is as yet no evidence. An overactive central nervous system, due to psychologic or endocrine factors, may be a contributing cause. A final factor, the mechanism of which still remains obscure, is the known association between chronic infection and "irritable heart."

Effects on Electrocardiogram of Calcium and Potassium Introduced into Blood.—Harris and Levin have attempted to ascertain the effects produced on the human electrocardiogram by alterations in the concentration of the bases normally present in the blood. The method employed consists in administering intravenously various bases to individuals and taking electrocardiograms and blood samples before and after such administration. Various calcium preparations were used for intravenous injections. The quantities of calcium in the blood serum were determined by the technic described by Clark and Collip in 1925. Intravenous injections of various quantities of a 5 per cent solution of potassium chloride were used in all the experiments. The quantities of potassium in the blood serum were determined by the method of Kramer and Tisdall. The authors did not succeed in raising to any pronounced extent the serum sodium by injection of sodium chloride. A rise in blood magnesium of from 2.8 to 5.2 mg. per hundred cubic centimeters did not affect the electrocardiogram in any particular way. When calcium or potassium salts are introduced into the blood stream of human subjects, the heart rate is definitely reduced, and this reduction may persist for a considerable time. No definite correlation could be found between the magnitude of the changes in the electrocardiogram and the concentration of calcium or potassium in the blood serum.

Ancylostoma Anemia.—Fikri and Ghalioungui investigated the dextrose tolerance of eighteen cases of pure ancylostoma infestation. In twelve there was some abnormality in the extent of the hyperglycemic response, its duration or its fall. In nine of these, two or more defects were associated. The blood sugar curves after intravenous injection of dextrose were determined in eight cases. They were normal and did not correspond to the respective oral responses. Interference with absorption caused in some way by the presence of the ancylostoma worms and by their bites in the duodenum is presented as a possible explanation.

Pulmonary Cysts in Adults.—Ameuille and Rendu believe that air cysts of the lungs may be congenital as well as acquired. Many infants with congenital cysts die young. In those who survive, the cyst becomes larger with increasing age. This is the reason why pediatricians see mostly congenital cysts and internists treating aged persons say that cysts of adults are acquired. There are naturally also differences in structure distinguishing them from normal air cavities or from hydatid or dermoid cysts. Difficulties in diagnosis arise when air cysts are the seat of inflammatory processes. Roentgenologic examinations cannot differentiate between ordinary cavities and cysts, even with the use of opaque substances, which do not always penetrate through the bronchi. Some authors have even mistaken cysts for a pneumothorax, and Vallebona had little success with his "stathographic" roentgenograms. Air cysts are not seen in middle aged persons. Unilocular cysts are of mediocre size, but all around them there may be found large emphysematous vesicles which become smaller as their distance from the central cyst increases. To give them a valid interpretation, it is necessary to know to which vascular system of the lungs they belong and what relation they have with other lesions.

Splenectomy in Chauffard-Still's Syndrome.—Loeper and his associates describe a case of polyarthritis with enlarged spleen and lymph nodes and increased temperature, which in the beginning was temporarily relieved by salicylates. The recurrence resisted all medication, and splenectomy was decided on. After a transfusion of 300 cc., a curvilinear incision was made on the left side of the abdomen just above the umbilicus. The spleen was found to be firm and adherent. The splenic vessels were ligated close to the hilus at the edge of the pancreas, and a few isolated vessels were attended to. Then the spleen was taken out and the gastrosplenic omentum sutured. Microscopic examination showed that the sinuses of the spleen were devoid of cellular elements in the midst of a hyperplastic reticulum. Their endothelial lining had proliferated, showing numerous karyokinesis; some foci of degeneration seemed to be due to hyaline transformation of vessels. The postoperative improvement of the patient was rapidly progressive, functional impairments disappeared and the joints became freer in their movements. Five weeks after the operation there was a sudden onset of bilateral bronchopneumonia, from which the patient died. This splenectomy for Chauffard's polyarthritis is, according to the authors, the third of its kind mentioned in the literature. Both preceding cases were rewarded with permanently favorable results.

- *Fragility of Capillaries in Pulmonary Tuberculosis: Modifications by Action of Vitamin C. G. Borsalino.—p. 273.

Fragility of Capillaries in Pulmonary Tuberculosis.—Borsalino made determinations of the resistance of the capillaries in 140 patients suffering from pulmonary tuberculosis, with and without hemoptysis. The determinations were made

before and after administration of an intravenous injection of 100 mg. of cevitic acid. Patients with grave hemoptysis as well as those suffering from intestinal complications or a cachectic condition were excluded. The resistance of the capillaries is almost normal in patients who do not have a tendency to suffer from hemoptysis. In hemoptoic patients it is low. In both instances the resistance of the capillaries increases immediately after administration of cevitic acid. The increase progresses for the first twelve hours after the injection. Then it diminishes slowly, and about twenty-four hours after the injection it is the same as it was before. Cevitic acid also proved to have a favorable symptomatic action by which the general condition and appetite of patients improved and the fever and quantity of sputum were favorably modified. The anatomic condition of the lungs, however, remained unchanged. In cases of actual hemoptysis the latter stopped but frequently reappeared when the cevitic acid treatment was discontinued.

- Twisted Ectopic Testicle in Infant: Case. J. Vizziano Pizzi.—p. 179.

Ether Enemas in Whooping Cough.—The treatment advised by Leone Bloise and Alvariza Perez consists in daily enemas of a solution prepared according to the following formula: 20 cc. of a 10 per cent solution of camphor in ether, 30 Gm. of eucalyptol and 100 cc. of a 4 per cent solution of aromatized oil in liquid petrolatum. The enema is given through a No. 14 or 16 Nelaton catheter introduced 15 cm. into the rectum. The dose for each enema is 5 cc. for infants, 10 cc. for children from 2 to 8 years of age and 15 cc. for older children. The treatment consists of eight enemas (one a day) and in grave cases, fifteen. The authors conclude that the ether enemas favorably modify the evolution of whooping cough and prevent the development of complications, especially of the respiratory tract. The number of attacks and duration of the disease are greatly diminished. The technic for administration of the enemas is easy and they may be given at home by the mother. Infants and children have complete tolerance to the treatment, which can be given with specific vaccines (freshly prepared) or with antispasmodic drugs, such as belladonna, for instance. Satisfactory results from the treatment were attained by the authors in 80 per cent of the cases in a group of eighty children who received the treatment.

Symptomatic Improvement of Emphysema from Pneumoperitoneum.—Piaggio-Blanco and his collaborators advise performing pneumoperitoneum, with repeated administration of large amounts of oxygen (2 liters at a time), in the treatment of grave emphysema associated with chronic bronchitis and asthmatic crises. After the treatment dyspnea diminishes, expectoration is more easy than before, the vital capacity increases and the patient can rest in the dorsal decubitus and feels greatly relieved. The improvement caused by the treatment is due to the elevation of the diaphragm with consequent restoration of its functions and regulation of the intra-abdominal pressure. During emphysema the equilibrium of intrapleural and intra-abdominal pressures is disturbed. The latter is negative. Pneumoperitoneum controls the disequilibrium and brings intra-abdominal pressure from negative to positive. Two cases are reported.

Specificity of Serologic Tests for Tuberculosis.—

Gerhartz demonstrates that the complement fixation reactions, which employ specific antigens obtained either from the pathogenic organism or from the tuberculous tissue, have proved specific in the animal experiment as well as in the clinical application. In the presence of tuberculosis, they are as a rule positive. If they are positive in the absence of tuberculosis, other organs may be tuberculous. They demonstrate biologic tuberculous activity, which is not necessarily identical with clinical activity. In case of negativity, the tuberculous tests should be repeated and, since different tests do not always produce identical results, several should be made on the same patient. Analysis of the cases in which positive tuberculous complement fixation reactions were obtained revealed that the reactions are positive not only in pulmonary and extrapulmonary tuberculosis but also in a number of other disorders, such as iritis, ulcer of the cornea, nonsyphilitic keratitis, hemorrhage and turbidity of the vitreous humor, retinal hemorrhage, neuritis of the optic nerve, Ménière's disease, angiospastic processes, lupus, polyserositis, multiple sclerosis and amyotrophic lateral sclerosis. The author says that it is not justified to designate a positive reaction as nonspecific merely because no typical tuberculous tissue changes can be found, for there are factors which suggest that these disorders might be of a tuberculous nature. He reaches the conclusion that the serologic tests for tuberculosis are a valuable aid in the differential diagnosis of tuberculosis and in the detection of hidden tuberculosis. However, for the estimation of the activity of the tuberculous process or for the prognosis, they are of slight value.

Aspects of Pseudobulbar Paralysis in Younger Persons.—Bini points out that the literature reports cases in which foci in the basal ganglions caused pseudobulbar paralytic manifestations. After citing some of these, he shows that most of these cases have in common a lesion on the external surface of the putamen, which partly involves the external capsule and the claustrum. The nucleus caudatus is less often involved. Occasionally the process spreads to the thalamus and in rare cases also to the internal capsule. However, the characteristic aspects of these cases are the foci on the external surface of the putamen. These foci may produce the symptoms of pseudobulbar paralysis, even if the process on the putamen does not involve the capsule, the thalamus or the nucleus caudatus. It is also noteworthy that rigidity predominates in these cases and that they are related to the arteriosclerotic muscular rigidity described by Förster. In the majority of cases, including those observed by the author, there exist severe degrees of calcification of the vessels so that the trophic factor plays a part in the genesis of the symptoms. A second group of cases of pseudobulbar paralysis concerns pontile foci and they are usually of an arteriosclerotic nature. The author says that among the most interesting cases of pseudobulbar paralysis are those in which the basal ganglions or only the corpus striatum are involved. It has been suggested by some that in these cases it is not so much paralysis as dystonia and Parkinson-like symptoms which predominate. To such cases, however, the term pseudobulbar paralysis could not properly be applied. Nevertheless, the older as well as the more recent literature reports cases in which the paralytic symptoms predominate over the striopallidal symptoms. Thus the question arises whether the striatum, in addition to its action on the tonus, may not also influence the motility. The author gives his attention to this question on the basis of two case reports concerning men aged 45 and 44 respectively. In the discussion of these cases he points out that there is no reason to assume that the striatum in addition to a tonic has also a motor function, for in the

majority of cases of pseudobulbar paralysis in which the striatum showed a lesion other parts of the brain were also involved, such as the pons in one of his cases. The pontile involvement seems to indicate that in such cases the striatum exerts only a modifying, not a determining, influence.

*Polycythemia Vera Ending in Agranulocytosis and Thrombocytopenia. H. Schnetz.—p. 110.

Salivary Glands and Pernicious Anemia.—Because perhaps other portions of the digestive tract, besides the stomach and the intestine, might play a part in the pathogenesis of pernicious anemia, Tempka gave his attention to the salivary glands. He describes his observations on a patient with pernicious anemia, in whom he resorted to the oral administration of saliva from normal persons. Over a period of seventy days, 20.33 liters of saliva was administered. A tabular report indicates the gradual improvement of the blood status and of the weight under the influence of the administration of saliva and also the renewed impairment of the blood status when administration of the saliva was interrupted for a while. The typical reticulocytic crisis developed on the sixth day of the treatment with saliva; that is, at about the same time it occurs in hepatogastrotherapy. The time of appearance of the reticulocytic crisis and several other factors indicate that the improvement which took place during the administration of saliva was not a spontaneous remission. In summarizing his observations the author says that the oral administration of normal saliva effects remission in a typical case of pernicious anemia. He cites several questions concerning the saliva therapy which require further investigation.

Polycythemia Vera Ending in Agranulocytosis.—Schnetz describes his observations on the involvement of the white blood picture in polycythemia. One case, which is described in detail, reveals (1) the typical symptoms of a polycythemia vera that could be traced back for five years and (2) the clinical aspects and the course of an acute (aleukemic) myelosis or agranulocytosis, respectively. As regards the symptom of polycythemia, which becomes manifest in a predisposition to thrombosis, this case is of interest because of a new localization. A thrombocytopenia pulmonalis was observed which, if watched for, might be found to occur with considerable frequency in such cases, the more so since some of the symptoms of polycythemia (attacks of cyanosis, dyspnea and so on) are identical with those of sclerosis of the pulmonary arteries (A. Posselt). In the literature to which they had access, the authors found no other case of polycythemia vera with such a severe leukopenic, agranulocytic reaction as in the first case described in this report. In a second case with typical symptoms of polycythemia there developed a phlegmon of the hand and a mild agranulocytic reaction. The latter subsided again, together with the phlegmonous process, apparently in response to the administration of vitamins C and A.

*Effect of Autohemotherapy on Agranulocytosis and Its Mode of Action. T. Sakurai.—p. 564.

Mistakes in Evaluation of Sternal Puncture.—Von Domarus emphasizes the necessity of recognizing the limits of the diagnostic use of the sternal puncture. He describes two cases which demonstrate that the result of the sternal puncture

may be misleading. In the first case the sternal puncture erroneously indicated a good regenerative capacity of the bone marrow, when the patient had an aplastic anemia or a myelophthisis, which terminated in death. The second case took a favorable course, although the two sternal punctures indicated a defective regeneration capacity of the bone marrow. On the basis of these cases, the author warns against an overestimation of the diagnostic value of sternal puncture.

Criticism of Sternal Puncture.—Hespap points out that the diagnostic use of the sternal puncture presupposes two factors: (1) that the sternal marrow is homogeneous in its cellular structure and (2) that there is a parallelism between the condition of the sternal marrow and the marrow of the other bones. After reviewing the scant literature about these two questions, the author reports his own studies on the sternal marrow of thirty-two cadavers, in none of which had there been a disease of the blood. Only twenty-two of the examined sternums had a homogeneous red marrow. In eight cases the sternal marrow was nonhomogeneous in that the cells from three distinct sites of puncture were different. In order to obtain information about larger portions of the bone marrow, the marrow of both femurs was examined in twenty-four of the cases. These observations prove that in one and the same patient the marrow in the long bones and in the sternum is not necessarily of a uniform character. The bone marrow apparently is not a homogeneous organ like the blood, and the diagnostic value of a sample of marrow taken at random should not be overestimated.

Autohemotherapy in Agranulocytosis.—In citing several case histories, Sakurai demonstrates that the severe as well as the mild forms of agranulocytosis, which occasionally develop after treatment with arsphenamine, can be counteracted by the injection of the patient's own blood. The author withdraws from 10 to 20 cc. of blood from the vein of the patient's arm and injects it immediately into the gluteal muscle. To avoid coagulation of the blood, the syringe is first moistened with citrate solution. The site of injection is massaged. The blood is injected every day or every second day until four or five injections in all have been given. The case histories indicate that the first injection effects a reduction in fever. The author suggests that the agranulocytosis after treatment with arsphenamine is a drug anaphylaxis. He also discusses the mode of action of autohemotherapy.

- Cardiac Neurosis. G. Tidow.—p. 605.

Chemotherapy in Brucella Abortus Infection.—In view of the favorable effects that had been obtained with prontosil in various infections, Berger and Schnetz decided to try this form of chemotherapy also in Brucella abortus infection. They report the clinical history of a man, aged 35, in whom the Brucella abortus infection did not respond satisfactorily to treatment with neoarsphenamine. After the neoarsphenamine treatment was discontinued, the patient was given daily three tablets of prontosil and three times each week an intramuscular injection of an ampule of prontosil. The response to this treatment was so favorable that the authors felt justified in reporting this case, realizing of course that a single case does not permit generalizing conclusions about the value of a treatment. They think that the prontosil should be tried in other cases of Brucella abortus infection.

Nystagmus in Tumors of Thoracic Portion of Spinal Medulla.—Hoff and Pözl observed spontaneous nystagmus in three out of six patients with tumors in the thoracic region of the spinal medulla. They admit that because of the small number of cases the figures are of no significance, but they think that the characteristics of the nystagmus which appears in these cases deserve attention. They observed that it has a slow and a rapid component. The rapid component is in the direction of the visual movements; it is entirely horizontal and appears

especially when the patient is standing, sitting or in the abdominal or dorsal positions. Turning the pelvis or rotating the legs arrests the nystagmus. These seem to be the only movements that cause cessation of the nystagmus. To be sure, in one case the completion of the lateral position was necessary to arrest it. After the surgical removal of the tumor from the thoracic portion of the spinal medulla, the nystagmus disappeared completely or only slight traces of it remained. As long as the nystagmus was at the peak of its development, pelvic movements toward either side and both lateral positions had the same effect, in spite of the fact that in the first two cases the spastic and parietic conditions were not equally severe on the two sides. In evaluating the significance of the described observations, the authors point out that they indicate the need of a careful examination of the nystagmus that develops in case of spinal tumor. Even if a spontaneous nystagmus is absent, it is advisable to subject these patients to the same examinations in order to determine whether some change in the position might not perhaps elicit a latent nystagmus. The differential diagnostic significance of this type of nystagmus is slight, because it occurs also in rare cases of multiple sclerosis; but it should be impressed on the nonspecialist in this field that the existence of a nystagmus does not necessarily speak either against a tumor of the thoracic spinal cord or for a multiple sclerosis.

Changes in Pancreas Following Roentgen Irradiation.—Seino made experimental studies on the hypertrophy of the islands of Langerhans and its relationship to the assimilation of sugar. He produced hypertrophy of the islands in rabbits by partial extirpation of the pancreas, by ligation of a part of the organ, by chronic starvation, by roentgen irradiation or by the combination of the two latter methods. Later the animals were subjected to oral and intravenous sugar tolerance tests. In the rabbits that had been subjected to partial extirpation or ligation of the pancreas, the assimilation of sugar proved to be greatly impaired; but in those in which the pancreas had been subjected to roentgen irradiation there was no noticeable deviation in the assimilation of sugar, in spite of the fact that the irradiation with the large dose of roentgen rays had produced atrophy or complete destruction of the pancreatic parenchyma. The islands of Langerhans showed no hypertrophy following roentgen irradiation, but there was a compensatory new formation of islands. A rabbit that had been subjected to chronic starvation showed hypertrophy of the islands of Langerhans but no hypoglycemia. He never observed hypoglycemia in connection with hypertrophy of the islands. Roentgen irradiation severely impaired the rabbit pancreas, but the effect of this impairment on the assimilation of sugar is less severe than in case of extirpation or ligation of a part of the pancreas. The irradiation was followed by hypoglycemia, but this had no connection with the condition of the islands of Langerhans.

Cutaneous Temperatures During Day and Night.—Scheurer and Zimmermann report their observations on fifty-eight men and women who were free from fever. Over 10,000

temperature measurements were made in all. Whereas the rectal temperature remained practically constant, the graph recordings of the cutaneous temperatures revealed small and large indentations. The fluctuations in the cutaneous temperatures are not dependent on the changes in pulse frequency. Moreover, the cutaneous temperature takes its course independent of the body temperature; it is always lower than the body temperature. Persons, whose cutaneous temperature was measured on the same day in the same room, with few exceptions gave identical curves of the cutaneous temperature. The same persons tested on different days showed a different course of the curves. A comparison of the cutaneous temperatures of men and women showed that during the day the cutaneous temperature of men is approximately 0.8 degree C. (1.4 degree F.) higher than that of women. During the night the cutaneous temperature of men decreases, whereas it seems to remain constant or increase slightly in women.

Serum Phosphatase in Carcinoma.—Baumert studied the modification of the serum phosphatase by activating and inhibiting substances in noncancerous and in cancerous patients. He describes activation experiments with magnesium chloride and inhibition experiments with calcium ions, sodium fluoride and so on. He thinks that, although the demonstrated activation and inhibition of the phosphatase of the carcinoma serum seems to indicate that this is characteristic for carcinoma serums, the behavior of the carcinoma serum in other respects does not support the unequivocal or diagnostic estimation of these aspects. An increase in the phosphatase values develops not only in carcinoma but also in obstructive jaundice, uremia with secondary contracted kidney and septic conditions. Moreover, other authors have observed it in degenerative bone disease and in tuberculosis. On the other hand, there were relatively low values in carcinoma of the upper respiratory and digestive tracts. Since in most cases the phosphatase values increase together with the progressive metastasization, it may be assumed that the high phosphatase values are the manifestation of a cytolytic process. In this connection the author calls attention to a parallelism between the phosphatase values and the cholesterol content in the serum. An increase in the cholesterol content is observed in obstetric jaundice, uremia, severe diabetes and carcinoma, and it is considered the result of cell impairing processes, in that the cholesterol which is liberated in cell disintegration enters the blood. A similar cause may be assumed also for the increase in phosphatase, particularly since phosphatase concerns chiefly the anaerobic metabolism, which is characteristic for carcinoma with its inadequate oxygen supply.

Prolonged QT Interval in Electrocardiogram.—Hegglin and Holzmann describe their investigations of 700 normal electrocardiograms. They observed a lengthening of the systole regularly in case of hypocalcemic conditions such as tetany, hepatic coma and uremia, but as the calcium content of the serum increases again it is reversible. Under toxic influences and metabolic and endocrine disturbances, the lengthening of the QT interval signifies a grave condition but the prognosis is not entirely unfavorable. In case of hypertrophic hearts in patients with hypertension and in the early and late stages of cardiac infarct, a slight prolongation of the QT interval is relatively frequent as the manifestation of a longer lasting stimulation in the pathologically changed portion of the heart. The lengthening of the QT interval, which occurs in pulmonary embolism and in collapse-like and comatose conditions, remains unexplained as regards its mechanism and significance. As can be seen from the ST-T portion of the electrocardiogram, in hypocalcemia the total process of excitation is abnormally prolonged, whereas in the other groups with QT lengthening it is chiefly the retrogressive phase that is abnor-

mally long. The authors conclude that the lengthening of the systole in the electrocardiogram occurs in various disorders. It may be a harmless accompanying symptom for instance of hypocalcemia, but also the manifestation of a severe impairment of the myocardial function.

Respiratory Quotient in Hyperfunction of Thyroid.—Bansi and Wolter say that the relation of carbon dioxide elimination to the intake of oxygen is dependent chiefly on the coordination of the combustion processes in the organism. After citing the respiratory quotient of the different basic foodstuffs (carbohydrates, fats, proteins) they state that in normal persons who take a mixed diet the respiratory quotient is usually around 0.85. An abnormal height of the respiratory quotient, that is, an increase to over 1, is observed in case of forced feeding with carbohydrates, when as the result of the transformation of carbohydrates into fats an excess of carbon dioxide is eliminated by the expiration. During starvation, on the other hand, the respiratory quotient often decreases to less than 0.7. However, the respiratory quotient is influenced not only by the food intake but also by other factors, such as the voluntary increase in the ventilation, observable during metabolic tests on frightened persons. In taking up the question of the respiratory quotient in patients with exophthalmic goiter, the authors point out that the scanty literature on this problem indicates that surprisingly often it is low. They decided to determine the respiratory quotient of patients with exophthalmic goiter and with other hyperthyroid conditions in their large material (225 cases). They observed a noticeable dependence of the respiratory quotient on the increased basal metabolic rate. The fact that with the increasing severity of the case the respiratory quotient is reduced almost to the level of the pure fat combustion indicates that the thyrotoxicosis severely taxes the carbohydrate metabolism and the carbohydrate stores of the organism. If, as the result of treatment of the hyperthyroidism, the basal metabolic rate decreases, there is nearly always a corresponding increase in the respiratory quotient up to normal values.

Histidine Treatment of Hemophilia.—Kohl observed that the enteral and parenteral administration of histidine considerably shortens coagulation (reaction time). This reduction was most noticeable in the sphere of the capillaries. Histidine also effected a noticeable reduction in the reaction time of the hemolyzed venous blood. It was possible to produce a greater and more lasting reduction of the reaction time by a combination of histidine with calcium and vitamin C. In three cases of true hemophilia, the reaction time of the capillary blood could be reduced or normalized by means of the oral administration of histidine, at least for the duration of the treatment, which may be carried out at intervals of from one to two days. The course of hemophilia is most favorably influenced by combining the permanent histidine treatment with the administration of calcium and vitamin C. One hemophilic patient, who was treated with histidine for a whole year, showed a considerable lessening in the hemorrhagic tendency. This hemophilic patient, who in the years from 1929 to 1935 had been confined to bed on account of articular hemorrhages for an average of 121 days annually, during 1936 when he received histidine treatment required only ten days of rest in bed on account of articular hemorrhages, which occurred during the intervals between the treatments. The two other hemophilic patients up to the time of this report had received a combination treatment with histidine, calcium and vitamin C for periods of six and eight weeks, respectively; during this time they had no serious hemorrhages.

- Male Sex Hormone and Estrogenic Hormone.**—Kun and Peczenik developed a modification of the so-called electrical ejaculation test, which enabled them to determine the

potency of androgens. They first determine the sexual potency of the animals by means of electrical stimulation, which elicits ejaculation in all normally developed male animals. Following castration, however, the electrical stimulation has this effect only after the animal has been treated with androgen. By means of this test the authors determined the marginal doses of various androgens and compared them with the doses that are required if they are given in combination with a constant quantity of estrogen (600 international benzoate units). They found that the addition of estrogen definitely reinforces the effect of androgen.

True Allergic Joint Diseases.—Aside from the allergic-hyperergic mechanism, which is assumed to play a part in the pathogenesis of chronic infectious arthritis, Maliwa directs attention to a small group of chronic articular changes for which a special pathogenesis must be assumed. He reports the clinical histories of two cases which represent two types of this special form of articular changes. In summarizing the characteristics of these two types he says that following allergic cutaneous or intestinal disorders first fleeting and later permanent articular swellings develop. These swellings are usually extremely painful. Even after they have existed for several years, the roentgenogram reveals no bone change, with the exception of an occasional moderate decalcification. There is usually no fever even in times of sudden exacerbations of the articular disorder. The sedimentation speed of the blood is never accelerated and may even be slightly retarded. The author stresses the importance of the differentiation of this process from chronic infectious arthritis. Exacerbations occur in both forms, but in the allergic form they are extremely sudden and occur often over night and without fever. A dietetic indiscretion may have preceded. The absence of allergic cutaneous changes does not indicate the absence of an allergic cause, for allergy may become manifest in diverse forms. In discussing the pathogenesis of the allergic articular disorders, the author suggests that an insufficiency in the fermentative decomposition of foods may play a part. He found the administration of a substance that inhibits histamine formation of therapeutic value.

*Agranulocytosis and Arsphenamine. H. Möschl.—p. 472.

Agranulocytosis and Arsphenamine.—Möschl points out that agranulocytosis has been observed repeatedly following antisyphilitic treatment with arsphenamine, but the combination with bismuth has often been regarded as the offensive factor in these cases. Cases in which arsphenamine exerted a therapeutic effect on an already existing agranulocytosis are relatively rare. Such a case is reported in this paper. Since a Plaut-Vincent angina seemed to be the cause of the agranulocytosis, it was decided to administer a dose of neoarsphenamine. Following this, the tonsillar membranes were cast off, the fever subsided and the blood picture improved. Since the sternal puncture revealed a normal bone marrow, it may be assumed that the excretion of the granulocytic elements from the bone marrow was blocked and not that the bone marrow had been impaired. The sternal puncture is an important diagnostic factor in such cases. In those that are similar to the reported one and whenever the sternal puncture reveals a well functioning bone marrow, a therapeutic attempt with arsphenamine seems advisable. In cases of impaired bone marrow the administration of arsphenamine does not seem desirable, although the question should be taken into consideration whether perhaps the arsphenamine would counteract the infectious process. The reported case is noteworthy also with regard to the relationship between aminopyrine and agranulocytosis. The patient had been given twice 0.3 Gm. of aminopyrine, but it is doubtful that such small doses would elicit agranulocytosis, especially since there were no signs of an allergy to aminopyrine.

- *Occurrence of Myelocytes in Normal Human Thymus and Relation This Observation to Theories of Genesis of Blood Cells. A. Bertelsen.—p. 397.

Bandaging in Fracture of Clavicle. E. Madsen.—p. 419.

Myelocytes in Normal Human Thymus.—Bertelsen states that promyelocytes, myelocytes and leukocytes were found in not inconsiderable quantities in the thymus in all cases examined in fetuses in the last third of pregnancy, in the new-born, children and in adults. The myelocytes divide and all stages up to leukocytes were seen. The number, the immature myelocyte forms and the preponderance of eosinophil types testify strongly against a vasogenic and for a local origin. In fetuses and children there were often in the interlobar septums large non-granulated mononuclear cells, from which many of the myelocytes established in this age group are assumed to develop. In adults this cell type was encountered only occasionally and in small numbers, but in the parenchyma large nongranulated cells were seen in direct relation to promyelocytes and myelocytes. The cells are believed to originate from the small lymphocytes and to be the most important mother cells for myelocytes. In spite of the frequent occurrence of "trachychromatic" myelocytes, direct granulation is not considered probable, since transition forms are lacking and since this myelocyte type occurs also in nonlymphatic tissue. Myelocyte formation from the thymus reticulum was not demonstrated.

*Investigations on Reliability of Friedman Test as a Test for Pregnancy. B. Heiberg.—p. 387.

Friedman Test for Pregnancy.—Through questionnaire addressed to attending physicians on the relation between the Friedman test and the clinical results with regard to pregnancy, Heiberg ascertained that there was complete agreement between the clinical diagnosis and the reaction in 98 per cent of 957 reactions, uncertain diagnosis in about 1 per cent and erroneous reaction in about 1 per cent. In the four erroneous positive reactions the differential diagnosis was between pregnancy and the climacterium; three of the five erroneous negative reactions were in women in the middle of pregnancy. The author says that in abortion and missed abortion the reaction may be negative or positive, depending on the functionality of the retained chorion tissue. In no case in this material was the diagnosis of extra-uterine pregnancy maintained in the face of a negative Friedman reaction, but according to earlier statistics the reaction is often negative in extra-uterine pregnancy.

Hypercholesterolemia in Castrated Men. G. Teilum.—p. 437.

Is Solution of Posterior Pituitary Misused? S. Horneman.—p. 440.

Galactosemia and Galactosuria in Hepatic Diseases.—Nissen reports the course of galactose tolerance in twenty-three patients with acute diffuse parenchymatous hepatitis. He states that galactose can always be established in the blood, also in normal persons, even when galactose is not eliminated. The galactose elimination in the blood therefore has to exceed a certain threshold before sugar can be demonstrated in the urine by the usual reduction methods. The blood galactose curve in hepatitis increases mainly in height, not in length. Elimination can vary greatly in hepatitis with the same loading of the kidneys, and as a rule it reaches its height corresponding to the acme of the parenchymal disturbance, showing that, parallel with the hepatic disorder, changes occur in the mechanism of galactose elimination. This explains the earlier failure to establish an agreement between the blood sugar values and the elimination after administration of galactose in hepatitis, and also that measurement of the galactose elimination as by Bauer's test must be a more reliable measure of the liver function than determination of the concentration of the blood galactose.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, F. G. Blake, New Haven, Conn.; Vice Chairman, T. H. Coffen, Portland, Ore.; Secretary, Fred M. Smith, University Hospitals, Iowa City.

SURGERY, GENERAL AND ABDOMINAL—Chairman, Hugh H. Trout, Roanoke, Va.; Vice Chairman, Frederick L. Reichert, San Francisco; Secretary, Henry W. Cave, 107 East 67th Street, New York.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY—Chairman, E. D. Plass, Iowa City; Vice Chairman, Harvey B. Matthews, Brooklyn; Secretary, Norman F. Miller, University Hospital, Ann Arbor, Mich.

OPHTHALMOLOGY—Chairman, Parker Heath, Detroit; Vice Chairman, A. Ray Irvine, Los Angeles; Secretary, Derrick T. Vail Jr., 441 Vine Street, Cincinnati.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY—Chairman, Gordon B. New, Rochester, Minn.; Vice Chairman, C. Coulter Charlton, Atlantic City, N. J.; Secretary, Leroy A. Schall, 270 Commonwealth Avenue, Boston.

PEDIATRICS—Chairman, Clifford D. Sweet, Oakland, Calif.; Vice Chairman, Edward B. Shaw, San Francisco; Secretary, Albert D. Kaiser, 16 N. Goodman Street, Rochester, N. Y.

PHARMACOLOGY AND THERAPEUTICS—Chairman, Russell L. Haden, Cleveland; Vice Chairman, Erwin E. Nelson, Ann Arbor, Mich.; Secretary, Irving S. Wright, 115 E. 61st Street, New York.

* Deceased.

PATHOLOGY AND PHYSIOLOGY—Chairman, Roy R. Kracke, Atlanta, Ga.; Vice Chairman, Maurice B. Visscher, Minneapolis; Secretary, J. J. Moore, 55 E. Washington Street, Chicago.

NERVOUS AND MENTAL DISEASES—Chairman, Samuel D. Ingham, Los Angeles; Vice Chairman, Groves B. Smith, Godfrey, Ill.; Secretary, Paul C. Bucy, 950 E. 59th Street, Chicago.

DERMATOLOGY AND SYPHILOLOGY—Chairman, Joseph V. Klauder, Philadelphia; Vice Chairman, H. J. Templeton, Oakland, Calif.; Secretary, Bedford Sheldire, 1719 Pacific Avenue, Dallas, Texas.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, Robert T. Legge, Berkeley, Calif.; Vice Chairman, Charles V. Craster, Newark, N. J.; Secretary, I. C. Riggins, State Office Building, Richmond, Va.

UROLOGY—Chairman, Albert J. Scholl, Los Angeles; Vice Chairman, George G. Reinle, Oakland, Calif.; Secretary, William P. Herbst, 1726 I Street, N. W., Washington, D. C.

ORTHOPEDIC - - - - - Pasadena, Calif.
 Vice Chairman, Os - - - - - etary, Robert V.
 Funsten, Universit; - - - - - Va.

GASTRO-ENTEROLOGY AND PROCTOLOGY—Chairman, Henry L. Bockus, Philadelphia; Vice Chairman, Descum C. McKenney, Buffalo; Secretary, A. H. Aaron, 40 North Street, Buffalo.

RADIOLOGY—Chairman, B. R. Kirklin, Rochester, Minn.; Vice Chairman, R. G. Taylor, Los Angeles; Secretary, John T. Murphy, 421 Michigan St., Toledo, Ohio

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1937

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1927. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2316.

For index to Organization Section see page 207B.

from professional secrecy standpoint, 1354
handbook, supplement to *Journal of the Medical Society of New Jersey*, 1183
organization, France, 1189; (3 methods) 1902
PRIAPISM, 322
PRIDE of Egypt Brand Tomato Juice, 885
PRISM Exercises: See Strabismus
PRIVACY: See *Medicolegal Abstracts* at end of letter M
PRIVIES: See *Organization Section Index*
PRIVILEGED COMMUNICATIONS: See also *Medicolegal Abstracts* at end of letter M
bill concerning professional secrets rejected, England, 983
preventive medicine from standpoint of, 1354
PRIZES, Alpha Omega Achievement Award Medal, 733
Alvaenga, (awarded) 648; (competition for) 980
American Association for the Advancement of Science, 214
Anderson-Berry (David) Medal, 1980
Argentine, 133
Belgian Mining Association prize for cancer, 1356
Casselberry Fund, 402
Citizens' Service Award, 211
Davidson lecture (competitive), 810
De Roaldes, 2147
Eisenman Award, 892
Fischer (L. C.), 732

PRIZES—Continued

German National Prize for Art and Science established, 1354
Gibson (Frank E.), 2146
Harben Medal, 2149
Hillebrand, 1346
Kober Medal, 1807
Lilly Award, 212
medal presented to Prof. Lemaitre, 311
National Safety contest winners, 1350
New England Obstetrical and Gynecological Society, 1268
New England Society of Psychiatry, 481
New York State health department for reports on pneumonia, 1127
Newman award, 979
Nobel (no more for Germans; list of those so honored) 1354; (1936 award to Dale and Loewi) 1443
Pennsylvania Society Medal, 1898
Phillips (John) Medal, 400; 1270
Radiological Society of North America, 127
Scott (John) medals, 1128
Southern Minnesota Medical Association medal, 1897
Strittmatter Award, 1549
University of Bern, 1900
University of Buffalo, 649
Wellcome, 1980
PROCAINE HYDROCHLORIDE crystals for spinal anesthesia, 206
ampoules—Abbott, 2203
injections: See Ankle, sprained; Sciatica
PROCTOLOGY, American Society, 1900
PROFESSIONAL SECRECY: See Privileged Communication
PROFESSIONS: See also Medicine, profession of compulsory retirement (Pomaret bill), France, 57; 486; 897
marriage among young professional men, Germany, 1554
price of professional liberty, [Ford] 1204—ab
regulation in public interest, [Wickenden] 1203—ab
PRONE Posture: See Posture
PRONTOSIL, Council report, 1888
red, prevention and treatment of puerperal infection, 1443
treatment of erysipelas, [Gottlib] 1382—ab
treatment of streptococcus infections, [Long & Bliss] *32; 48—E; 976—E; [Mellon & others] *1858
treatment of streptococcus meningitis, [Anderson] *151; [Weinberg & others] *1948
treatment of undulant fever, [Berger] 2262—ab
PRONTOSIL ALBUM: See Sulfanilamide
PROXYLIN: See Sulfanilamide
PROPRIETARIES, continuous fight with pharmacists, Germany, 654
PROSTATE: See also Urethra, prostatic abscess, [Drucker] 2086—ab
cancer, 742; [Kolmert] 1226—ab
cancer metastases, generalized osteoplastic form, [Van Bogaert] 513—ab
cancer metastases to bone with increased phosphatase activity, [Gutman] 235—ab
disorder (obscure) of tuberculous origin, 663
hypertrophy, estrogen treatment, [Cunéo] 601—ab
hypertrophy, 557 Gm. prostate removed surgically, [Middleton] *1967
hypertrophy, treatment, 322
regrowth after enucleation, 321
tuberculosis, [Moore] 1835—ab
PROSTATITIS, chronic, 321; 2160
chronic, may cause bleeding after coitus, 2159
Gonorrheal: See Gonorrhea
treatment of non-gonorrheal form, 751
Tuberculous: See Prostate, tuberculosis
PROSTIGMIN as aid in diagnosis of myasthenia gravis, [Harvey & Whitehill] *1329
treatment of myasthenia gravis, [Thorner] 1449—C
treatment, oral, warning, [Goodman & Bruckner] *965
PROSTITUTES, bismuth prophylaxis of syphilis in, 752
houses of prostitution, closing, France, 217
in Soviet Union, 2239
new penal code, Rumania, 408
venereal disease in, 1274; 1729
PROTAMINE Insulin: See also Diabetes Mellitus
Zinc & Helin (Insulin, Lilly), 641
Zinc Insulin, (N. M. R.) 640; 644—E
Zinc Insulin—Mulford, 641; 973
PROTEIN: See also Insulin; Thyroid protein allergy (specific) as cause of gout and rheumatism, [Gudzen] 1928—ab
consumption of 1,000 New York residents, [Ashe & Mosenthal] *1160
deficiency, [Jones] 597—ab
glycemic response to, [Conn] 150—ab
in Blood: See Blood proteins
in Milk: See Milk
in Vegetables: See Vegetables
of foodstuffs, nutritional value, [Swaminathan] 1838—ab
therapy (nonspecific), Council investigation, 1513
therapy (nonspecific), sensitization to milk from, [Bernstein & Ginsberg] *193; 209—E
PROTEOLYSIS Test (Fuchs): See Cancer diagnosis
PROTHROMBIN: See Blood coagulation

PRURITUS ani; triple distilled water treatment, [Bacon] 2165—ab
vulvae, achlorhydria an etiologic factor, [Swift] 1754—ab
without primary skin lesions, [Mount] 1833—ab
PSEUDARTHROSIS, treatment, [Martin] 2084—ab
PSEUDO-ANGINA: See Angina Pectoris
PSEUDO-ATROPHY: See Nerves, optic
PSEUDOTUMOR, hemophilic, [Fior] 149—ab
PSITTACOSIS outbreak in Buenos Aires and Tandil, 1555
PSORIASIS, arthropathia psoriatica, [Jeghers & Robinson] *949
of finger nails, 1738
treatment, injecting emulsion prepared from scales, 579
PSYCHIATRISTS, All-Union Conference of (second), 988
Congress of French Alienists, 2236
PSYCHIATRY: See also Organization Section Index
American Association, 1662
American Board examinations, 815
Belgian Congress, 1815
conference on, Colorado, 1805
diagnostic services to federal courts, U. S. Public Health Service report, 894
International Congress on Child Psychiatry (first), 1980; 2052
neuropsychiatry, course at Menninger Clinic, Topeka, 648
New England Society of, awards, 481
research, A.M.A. resolution on, 2225
PSYCHONEUROSIS; aeroneurosis, "pilot error," [Barach] *1868
gastric, 496
PSYCHOSIS: See also Mental Disease
circumscribed cranial osteoporosis with, [van der Helde] 344—ab
Depressive: See Melancholia; Mental Depression
etiology, atabrine, [Allen] 1217—ab
in identical twins, 2160
indigestion and tube feeding, 1737
thyrotoxicosis with, [Friedman] 842—ab
treatment, narcosis, [Alexander] 76—ab
PSYCHOTHERAPY, cooperation with medical schools, 1726
PTERYGOPALATINE FOSSA, phlegmon from injury to hard palate with lollipop stick, [Schonfeld] *194
PUBERTY: See Adolescence
PUBIS: See Alopecia, pubic
PUBLIC HEALTH: See Health
PUBLIC SPEAKING course at Indiana Medical School, 1127
